THE ENGINEER.

The Shipping, Engineering and Machinery Exhibition at Olympia.

The Shipping, Engineering, and Machinery Exhibition at Olympia.

THE twelfth Shipping, Engineering and Machinery Exhibition at Olympia, London, which was opened yesterday by the Earl of Athlone, occurs towards the end of that part of the year when the meetings of institutions, societies, and other bodies are least numerous and therefore provides engineers with the opportunity to meet their friends and acquaintances after a separation possibly extending to several months. Fresh subjects are available of which to talk, there are holidays, good or bad, to discuss, and should the conversation languish there are always the objects on a nearby stand to reinvigorate it. In fact, for a fortnight Olympia becomes the meeting place of engineers from all over the country, from the Continent, and, we hope and believe, from many other parts of the world as well. Each biennial Exhibition, though similar at first sight to its predecessors, has an individual character. This year, for instance, electrical engineers may suffer some slight disappointment, for the names of several familiar firms are absent from the catalogue. But against this loss may be placed the outstanding merit of the oil engine exhibits. Practically every well-known oil engine firm in the country is represented, while at least one firm not previously interested in the high-speed type has such an engine on its stand. Looking at the oil engine exhibits as a whole, it is interesting to note that a revival of interest in the horizontal type appears to be on the way, for several examples are to be seen, one of considerable size. The development of the high-speed type is proceeding as rapidly as ever, and an examination of the stands is sufficient to show that it is applied to a range of duties in the marine, industrial, and transport fields almost, if not quite, as wide as that of its slow-speed cousin. At the same time it is finding new spheres of usefulness for which the greater weight and size per horse-power of the slow and medium speed engines makes them unsuitable. In consequence of the importance of the oil engine exhibits a considerable proportion of this Supplement is devoted to them.

In other directions the Exhibition is not wanting in interest. There is the usual display of steam engineering plant. The instrument section will be particularly interesting to those with a liking for cunning mechanisms and the ingenious application of physical and chemical facts to engineering usage, and there are pumps and refrigerators, welding and metal cutting devices, and a host of such things as belting compounds, soldering fluxes, &c. British machine tools are unfortunately absent for the most part, owing to the affiliation of the majority of the firms in Associated British Machine Tool Makers, Ltd., while the display of foreign tools is not, we think, so good as in previous years, possibly as a result of the imposition of tariffs. Some visitors, no doubt, will consider the Exhibition less good than its predecessors; others will claim it to be the best of many. We leave our readers to judge for themselves.

KELVIN, BOTTOMLEY AND BAIRD, LTD.

One of the principal exhibits of Kelvin, Bottomley and Baird, Ltd., of 18, Cambridge-street, Glasgow, is the authentic "Lord Kelvin" dry card compass with all the latest improvements, including the coach spring suspension and mattress pivot. It is suitable for use where there is severe vibration. Liquid compasses, including the "Stabol" standard dead beat instrument, which is claimed to be remarkably free from disturbance under the most exacting conditions of vibration, and liquid steering compasses, including the "Vertical Card" pattern, in which an optically projected image of the card is shown in the vertical plane, are other exhibits. There are also compasses for use in small yachts and motor boats, and on aircraft, and sounding machines with all the latest improvements. The latter are of the motor and hand-driven types for sounding from the bridge or aft. Among them is a $2\frac{1}{2}$ H.P. machine with 500 fathoms of wire, for use in high-speed vessels.

A new hotwell gauge exhibited has been designed to overcome the difficulties associated with the application of such a gauge to hotwell tanks working on totally enclosed systems. These difficulties arise chiefly from the vacuum in the vapour space above the water surface in the tank, necessitating a pressure equalising connection between this space and one side of the gauge and from the liability of this connection to become partly flooded by condensation from the warm hotwell vapour. When this connection is of considerable length and when for the sake of convenience the pipe is small this tendency is serious. Consequently a system has been devised in which the connections between the gauge and tank are maintained in a "drowned" or intermittently filled condition. Essentially the gauge consists of a mercury U tube, the respective sides of which are connected to the hotwell tank at its lowest and highest points by means of two brass pipes. Both pipes pass through the bottom of the tank, but while one terminates just above the bottom, the other passes up as an internal standpipe and ends in an overflow orifice near the top of the tank. Near the gauge a water circulating pump is inserted in a short by-pass line provided with two cocks, disposed between the two ends of the tube. With a single setting these cocks serve to by-pass the U tube and to establish a continuous circuit from the bottom to the top of the tank *viâ* the external pipe line.

By operating the pump this circuit can then be entirely flushed and filled with the hotwell water drawn from the bottom point and be delivered to the top point of the hotwell tank, where it overflows freely into the main body of the tank. The cocks are then made to close the by-pass and to introduce the U tube into the "drowned" circuit. Under these conditions the vacuum within the tank operates equally on each side of the gauge and produces no effect on the reading. On the side connected to the top point of the tank the gauge is subjected to the head of water corresponding to the height between itself and the top of the tank, whilst on the other side connected to the bottom point of the tank it is subjected to the head of water corresponding to the height between itself and the actual level of the water in the tank. As the gauge reading is the difference of these two quantities, it is a direct measure of the distance from the tank top to the existing water level; in other words, the quantity of water contained in the tank.

Other gauges shown are suitable for indicating the quantity of fuel oil or other liquids in tanks and for giving boiler water levels at any convenient position. Space does not permit us to make reference to several additional exhibits, which consist, among other things, of a vibrometer for vibration tests, semaphores, morse lamps, petrol gauges for aircraft, clocks, and telescopes.

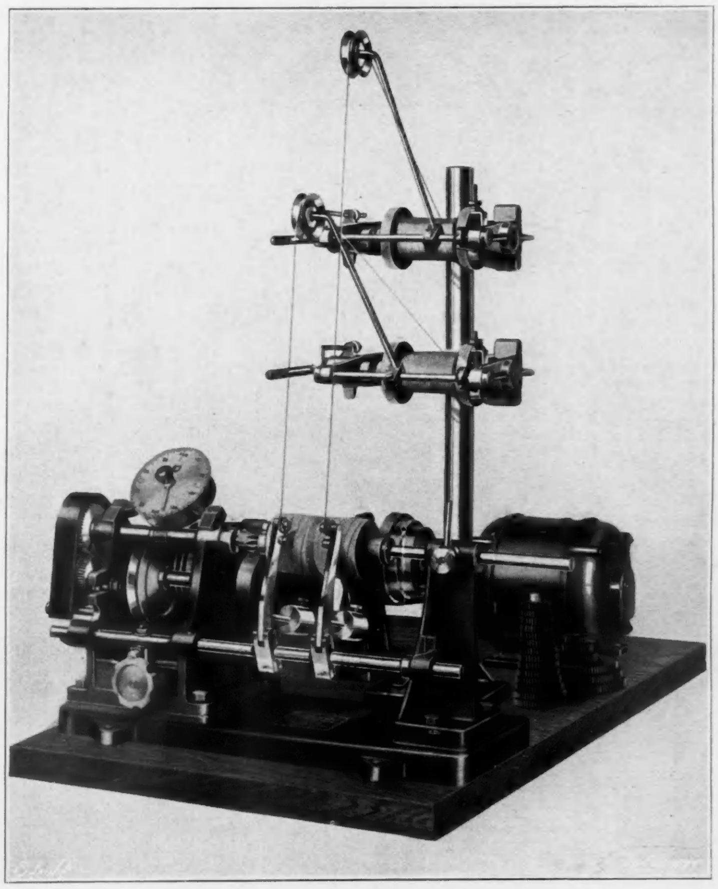

FIG. 1—CRISS-CROSS COIL WINDER—AUTOMATIC COIL

THE AUTOMATIC COIL WINDER AND ELECTRICAL EQUIPMENT COMPANY, LTD.

A comprehensive range of coil winding machines is being shown by the Automatic Coil Winder and Electrical Equipment Company, Ltd., of Windsor House, Douglas-street, S.W.1. Two new machines are the criss-cross coil winder and the Douglas multiple winder, shown in Figs. 1 and 2 respectively. The former, which can be hand or power driven, winds self-supporting wave-wound coils composed of from $\frac{3}{32}$in. to approximately $1\frac{3}{4}$in. width of covered wire of 46–20 S.W.G. As the wire reel carriers form separate units and as the stand will accommodate from one to four of them, one coil can be wound alone or two, three, or four coils may be wound simultaneously. Each of the reel carriers can be adjusted independently and can be made to take up any required position. The winder is driven through machine-cut gears. A sliding back centre is provided and any type of driving mandrel can be fitted to the driving spindle, or tubes can be held between the centres. Automatic brakes give the required tension on the wire and prevent overrun of the supply wheels when the machine is stopped. A worm-driven revolution counter to be seen on the left of the machine can be set to zero on the completion of winding.

The "Douglas" multiple-coil winder shown in Fig. 2 is for winding small coils from $\frac{1}{8}$in. to $\frac{3}{4}$in. in width and any number of coils within the range 1 to 4 can be wound simultaneously, according to size with wires of 48 to 32 S.W.G. A special motor, capable of running at 6000 r.p.m. and controlled by a foot pedal, forms the winding head, whilst an adjustable back centre supports the winding mandrel. The wire guide arms are capable of lateral adjustment. As in the case of the other machine, the wire reel carriers form separate units and the stand will take from one to four of them. Each reel carrier can also be independently adjusted to any required position and is fitted with an automatic brake which gives the wire the required tension when the machine is stopped. A five-figure direct-reading counter is to be seen on the extreme left of the machine.

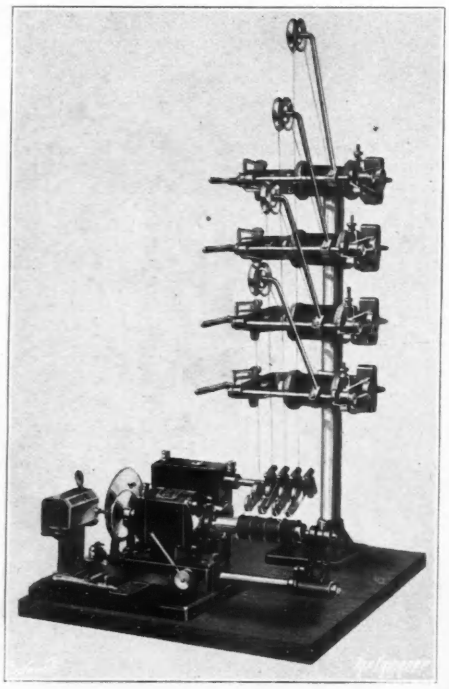

Fig. 2—Multiple Coil Winder—Automatic Coil

The Bergius Company, Ltd.

The range of engines displayed on the stand of the Bergius Company, Ltd., of 254, Dobbies Loan, Glasgow, C.4, includes a Kelvin sleeve valve engine for petrol, gasoline, or benzine fuels, Kelvin-Ricardo engines for paraffin, petroleum, or kerosene fuels, and Kelvin-Diesel engines for heavy fuel oils.

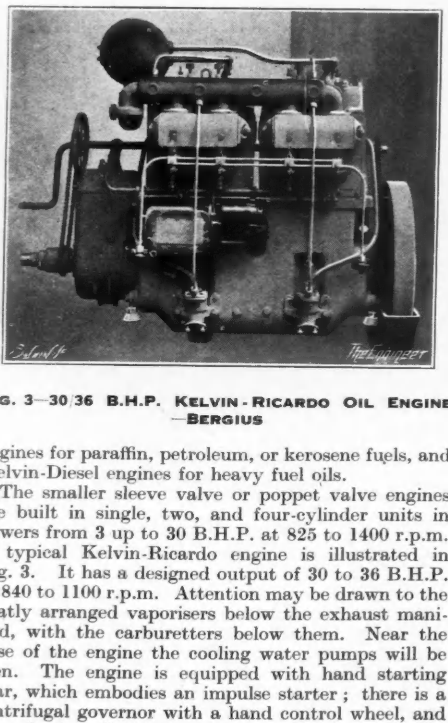

Fig. 3—30/36 B.H.P. Kelvin-Ricardo Oil Engine —Bergius

The smaller sleeve valve or poppet valve engines are built in single, two, and four-cylinder units in powers from 3 up to 30 B.H.P. at 825 to 1400 r.p.m. A typical Kelvin-Ricardo engine is illustrated in Fig. 3. It has a designed output of 30 to 36 B.H.P. at 840 to 1100 r.p.m. Attention may be drawn to the neatly arranged vaporisers below the exhaust manifold, with the carburetters below them. Near the base of the engine the cooling water pumps will be seen. The engine is equipped with hand starting gear, which embodies an impulse starter; there is a centrifugal governor with a hand control wheel, and the spherical silencer is water cooled. This engine is the largest Kelvin-Ricardo shown, the other three being two 15 to 18 B.H.P. engines with two and four cylinders and a $7\frac{1}{2}$ to 9 B.H.P. twin-cylinder unit. The two largest engines on the stand are of the Kelvin-Diesel type, the design of which has been developed by Mr. Walter Bergius in collaboration with Mr. H. R. Ricardo. We illustrate on page ix, Fig. 34 the four-cylinder 88 B.H.P. unit. The complete range includes one to six-cylinder units, designed with an output of 22 B.H.P. per cylinder at 750 r.p.m. The bore of the cylinders is 6in., with a stroke of 9in. A deep narrow crank case is employed, to which the cylinder casings are bolted. The valve gear is of the overhead type, operated by push-rods. The balanced crank shaft is of large dimensions and the whole of the lubrication for the bearings and running parts is automatic, with a plunger pump feed. The water circulating pump is of the ram type and works with a large air chamber. Means are provided to regulate the flow of water to the jackets, thereby facilitating starting operations and running at low engine speeds. The reverse gear is of the standard Kelvin pattern.

The Submarine Signal Company (London), Ltd.

The majority of our readers are already familiar with the principle of the "Fathometer" depth sounding apparatus manufactured by the Submarine Signal Company (London), Ltd., of 9, Victoria-street, and exhibited at Olympia. It will be remembered that, to put it very briefly, an electric oscillator is installed in a suitable position near the keel of a ship and sends out a sound at convenient intervals. Each sound, as reflected from the sea bed, is received by a hydrophone, and the time elapsing between the emission and reception of the sound is electrically measured. This time interval is, of course, directly proportional to the depth beneath the keel of the vessel, and, in fact, the electrical indication is automatically converted at once into a visual one on an instrument, usually mounted in the chart-room. Since they were first produced, considerable improvements have been made to "Fathometer" sounding devices. Costs of manufacture have been reduced, while at the same time ease of installation has been so carefully studied that it is now possible with very little trouble to fit such ships as small trawlers and the like with the device. For instance, the "Coastal" type, indicating depths up to 90 fathoms, has an all-mains amplifier; and a transmitter and hydrophones sufficiently small to be mounted between the frames of the ship. No cutting of the ship's skin, and therefore no dry-docking, is necessary. The instrument illustrated in Fig. 4 is especially designed for such craft as Channel steamers and coastal shipping, and gives a finer and more accurate indication of shallow water depths up to 45 fathoms. It is interesting to note that among other ships fitted with this particular type of instrument is the m.y. "Trenora," recently described in our columns.

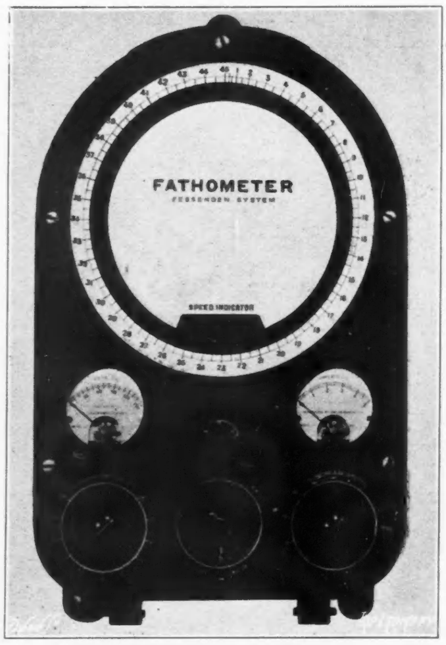

Fig. 4—Shallow Water "Fathometer"—Submarine Signal

B.E.N. Patents, Ltd.

The exhibits of B.E.N. Patents, Ltd., consist of a selection from the complete range of portable and fixed spray-paint plant and equipment. Two particularly interesting exhibits are the "Pneu-Matic 12" portable two-gun spray-paint plant, and the "Handi-Spray" outfit. The "Pneu-Matic 12" is designed for multi-gun spray work, as well as for the operation of pneumatic scrapers, riveters, and light chippers, and for all cases where mobility is of much importance. The single-cylinder, air-cooled compressor is belt-coupled to a $1\frac{1}{2}$–2 H.P. air or water-cooled petrol engine, both being securely bolted to a rigid all-steel channel base mounted on pneumatic-tired wire wheels. The two air receivers are of tubular construction and are carried lengthwise along the underside of the channel base, thus affording an exceptionally long passage for the compressed air. An oil and water separator is fitted at the forward end of the machine, and is provided with two outlet cocks for air hoses, thus ensuring the delivery of dry air that is cool and free from oil or condensed water, for which latter drainage cocks are provided. Regulation of air pressure is effected by means of a diaphragm head unloader, the controller being fitted alongside the pressure gauge in a position convenient to the operator. The engraving—Fig. 5—shows a side view of the equipment.

The "Handi-Spray" outfit is a self-contained and compact unit capable of handling cellulose lacquers, paints, and distempers. It comprises a B.E.N. type A.O. single-cylinder, air-cooled compressor, a $\frac{1}{4}$ H.P. electric motor controlled by a convenient double-pole switch, and an efficient oil and water separator with pressure gauge and relief valve. The outlet from the compressor is connected to the oil and water separator by a coiled copper after-cooler carried round the fan fly-wheel in such a manner that the air is thoroughly cooled and cleaned before being delivered to the spray gun. The complete unit is mounted on a light, rigid steel base carried on four rubber buffers, the drive from the motor to the compressor being taken by an endless silent "V" belt. Provision is made for belt tensioning. As it is only 18in. long, $9\frac{3}{4}$in. wide, 16in. high, and weighs 74 lb., the outfit justifies its title.

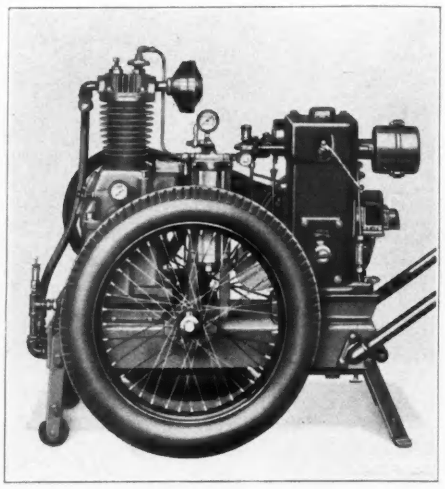

Fig. 5—"Pneumatic 12" Spray-Paint Plant —B.E.N. Patents

The Renold and Coventry Chain Company, Ltd.

Chains in an almost bewildering variety of applications are to be seen on the stand taken by the Renold and Coventry Chain Company, Ltd., of Didsbury, Manchester. For power transmission chains suitable for horse-powers up to 1200 are to be seen, while the standard range of conveyor chains covers breaking strengths from 1700 lb. up to 85,000 lb. Together with chain couplings for horse-powers up to 600 and speed transformers for increasing or decreasing speed, there is altogether an excellent demonstration on the stand of the capabilities of chains.

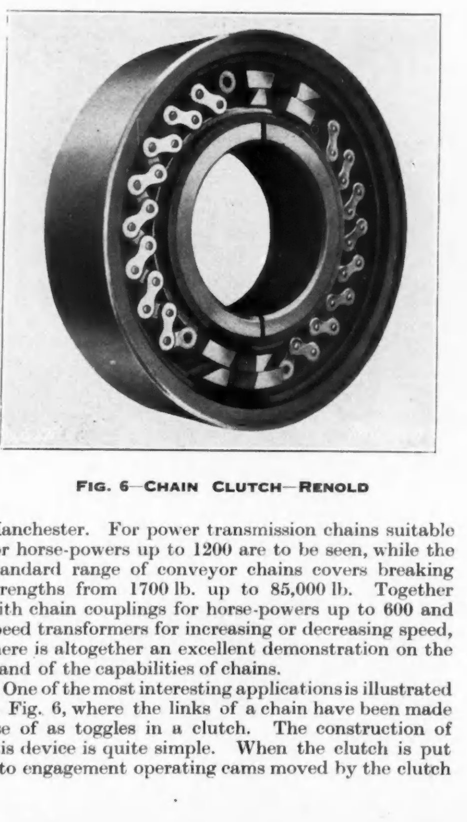

Fig. 6—Chain Clutch—Renold

One of the most interesting applications is illustrated in Fig. 6, where the links of a chain have been made use of as toggles in a clutch. The construction of this device is quite simple. When the clutch is put into engagement operating cams moved by the clutch fingers compress the chain. Each link then acts as a toggle pressing outwards on to an expanding friction ring that grips the internal diameter of one member and pressing inwards to contract a friction ring to grip the external diameter of the other member. The numerous points of contact which the chain makes when under compression ensure uniform pressure throughout the circumference of the friction rings. Although either side of the clutch may be the driver, it is normally mounted on the driven shaft as close as possible to the shaft bearing. A double engagement bobbin is also made for use where alternate engagement between two drives is required. The largest clutch is made for a maximum rating of 50 H.P. at 600 r.p.m. Another interesting application of chain to be seen on this stand is the push-pull remote control gear suitable for the operation of clutches and similar units. The roller chain is enclosed in weldless steel tubing and the system may be applied with a neatness comparable with that of an electric wiring system. A maximum effort of 100 lb. may be exerted in one direction and of 20 lb. in the other and a maximum of three bends can be used in any installation. These bends may be in two planes.

Murex Welding Processes, Ltd.

On the stand of Murex Welding Processes, Ltd., of Ferry-lane Works, Forest-road, Walthamstow, E.17, there is a comprehensive range of welding plant, electrodes, and welded objects. A full-sized portion of a cargo ship's midship bilge section shown is similar to that exhibited some months ago in Glasgow and described in a paper read by Mr. Adam, chief ship surveyor for the British Corporation Register of Shipping and Aircraft, before the Scottish Institution of Shipbuilders and Engineers. The exhibit at Olympia differs from that at Glasgow, in that the vertical tank side plate is shown as it would appear in laying off; and by the carrying outboard of the tank top strake to form a girder flange and the under scarfing thereof by the side frame knees. This assembly offers a jointing system impossible of attainment in a riveted ship without the introduction of a line or lines of rivets in a particularly undesirable position.

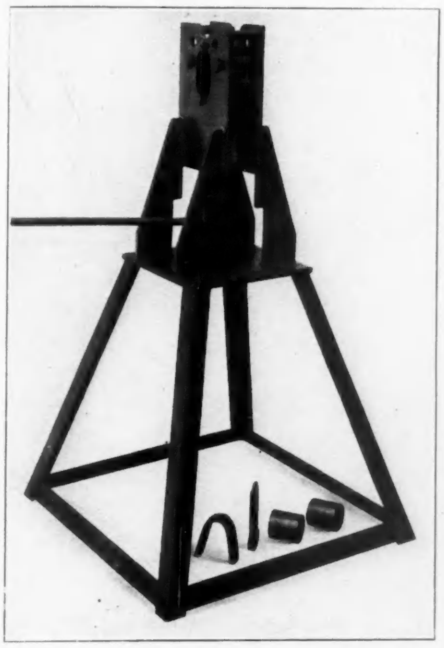

Fig. 7—Machine for Testing Welds—Murex

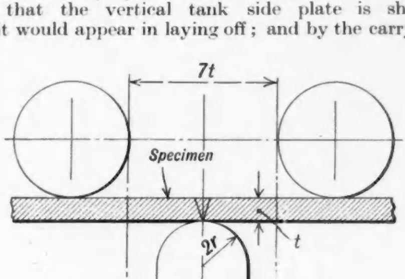

Fig. 8—Diagram Showing Arrangement of Weld Testing Machine—Murex

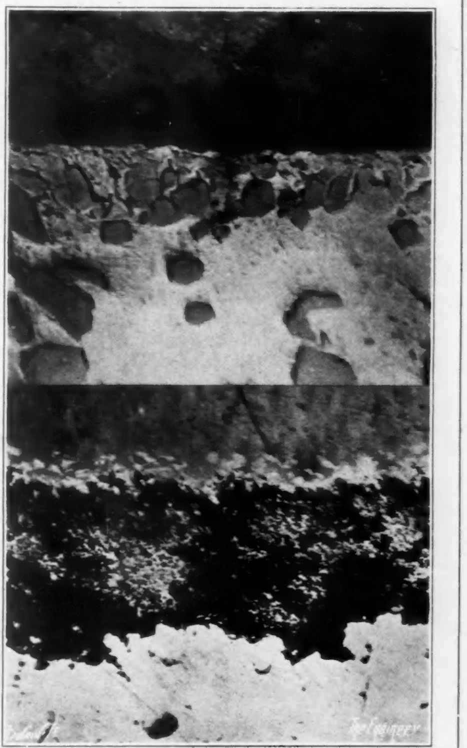
The welding plant shown includes a 600-ampère single-carcase motor generator set for high-speed welding, a portable static transformer welding set, and a detachable unit motor generator set for welding railway crossings, structures, &c. An automatic coal gas cutting machine lent by the British Oxygen Company, Ltd., is another exhibit. Demonstrations are being given of the welding of all kinds of special steels and alloys by the company's patented electrodes, including one of straight gap welding in thick plate. Several new types of electrodes for arc welding are being used. A hand operated testing machine shown has been designed to provide a simple, rapid, and inexpensive method of carrying out a bend test as a measure of the ductility of weld metal and welded joints. The bend test as applied to weld coupons (usually butt-welded plates with a single V) is said to be the most suitable method of evaluating that quality of weld metal or of a welded joint. The bend test offers the advantage that by a single test the ductility of the weld metal as deposited in practice and that of the joint as a whole can always be obtained, whereas in the tensile test no measure of ductility is obtained if the specimen breaks outside the gauge points. The machine shown in Fig. 7 consists of a mild steel table on which a hydraulic jack is mounted, the head of the jack being slotted to take a plunger which makes contact with the underside of the specimen along the welded joint, as shown in Fig. 8. The radius of the plunger is usually $2t$, as indicated, whilst the clearance between it and the rollers shown in Fig. 8 should be approximately $1\frac{1}{2}t$, the specimen being tested so that the upper part of the V is in tension. The most suitable methods of determining the degree of ductility consist of (1) measuring the angle of bend, and (2) the elongation of the outer fibres. The first method is well known and does not call for description, but the second method may need explanation. It consists in scribing, or preferably marking with a rubber stamp, fine lines across the specimen equidistant from the centre line of the weld and at a distance of t, $2t$, or $3t$ apart. During the testing of a specimen bending is continuous until any defects which open up are enlarged to a width of $\frac{1}{16}$ in., when the test is stopped and the specimen removed for the determination of the ductility of the welded joint, measurement with a flexible rule being a convenient method of determining the elongation.

The Soldo Company.

The compound known as Soldo, and made by the Soldo Company, of Sicilian House, Southampton-row, London, is non-acid and consists of a powder which is a combination of fluxes and metal. It is claimed to be suitable for tinning all metals, except aluminium, even when rusty, corroded, greasy or oily, with no previous preparation whatsoever. The method of use consists of heating the metal to be tinned in a gas flame to a temperature judged to be sufficient. It is then removed, and "Soldo," which is a greyish white powder, is sprinkled over the area. Fumes are evolved, the compound appears to melt, and a continuous tinned surface is produced. Tests were conducted at the National Physical Laboratory on the tinning of phosphor bronze commercial rolled strip, "Ohmal" strip, manganese bronze commercial rolled strip, steel, cast iron, and rusty steel. Microscopic examination of the joints showed in all cases interpenetration between the metal and tin. With manganese bronze the extent of the interpenetration was observed to be four to five times, and with phosphor bronze about twice as great as when ordinary workshop methods of tinning were employed. The upper microphotograph—Fig. 9—shows tinned manganese bronze at a magnification of × 600. Diffusion has proceeded to a considerable depth. The other engraving—Fig. 10—at a smaller magnification (× 200) shows manganese bronze jointed to cast iron. The upper part is the bronze, the lower part cast iron, and the central region consists of tin, the black areas, according to the N.P.L. report, being probably the results of interpenetration with the cast iron.



Figs. 9 and 10—Microphotographs of Tinned Surfaces—Soldo

C.A.V.-Bosch, Ltd.

Magnetos as shown in Fig. 11, with stationary windings and cobalt steel magnets, are being exhibited by C.A.V.-Bosch, Ltd., of Acton, W.3. The contact breaker and distributor form a separate unit which on a four-cylinder engine runs at half the usual speed and at one-third of that speed on a six-cylinder engine. A considerable reduction in the wear of the moving parts is claimed to be secured and maintenance is reduced to a minimum. Automatic advance mechanism can be fitted to the distributor instead of to the main driving shaft, with the result that the automatic mechanism is not subjected to the relatively large moment of inertia and large driving torque associated with the main rotor. As on the fixed part of the machine space is not restricted, a heavy primary winding is permissible and the secondary can be provided with a liberal amount of insulation. A greatly improved slow-speed performance and a wide range of ignition advance are the makers' principal claims. Other exhibits consist of car dynamos, switchboards, starters, and fuel injection equipment.

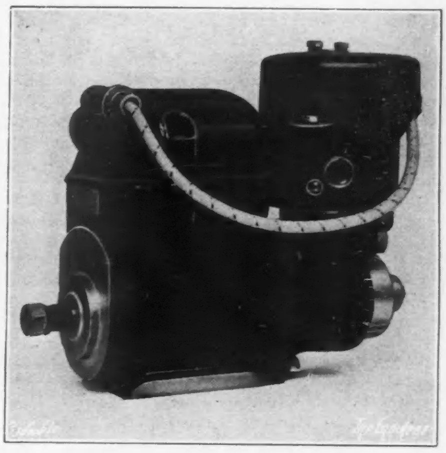


Fig. 11—Magneto—C.A.V.-Bosch

John Lilley and Son, Ltd.

Nautical instruments of many kinds are to be seen on the stand taken by John Lilley and Son, Ltd., of North Shields. The "Unit" compass in its several forms takes pride of place, but the many other instruments such as the "Q.E.D." pelorus for taking bearings and the measuring of horizontal angles, &c., and the "Sceptre" depth recorder, particularly in its adaptation for the use of yachtsmen, deserve attention.

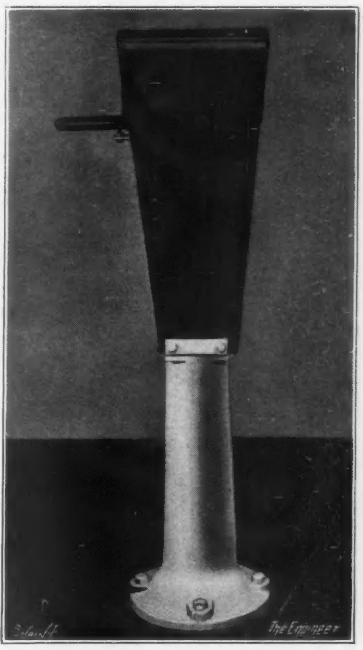

Fig. 12—Stern Fog Signal Emitter—Lilley

It may be remembered that in January, 1934, under the new International Agreement for the

Safety of Life at Sea, vessels over 350ft. long will have to carry a stern fog signal. It will easily be appreciated even by those whose seafaring adventures have been limited to an occasional trip in a cross-Channel boat, that if a stern fog signal is to be effective the noise it gives out must readily be differentiated from other similar signals at present in use, such as Klaxons, steam whistles, syrens, and the bell mounted forward. In the approaches to all seaports there is inevitably a considerable congregation of shipping at the coming down of fog to limit visibility. Although an experienced sailor hearing the sound of the foc'sle bell through the fog and knowing how the tide is flowing, may be able to guess successfully how the vessel lies, there can be no doubt that he will be greatly assisted in avoiding the invisible ship and finding a safe anchorage for his own if the noise of the bell is immediately followed by the sounding of a gong on the poop. John Lilley and Son, Ltd., have designed and are showing at the Exhibition the gong illustrated in Fig. 12. It has been designed to fulfil all the requirements of the Board of Trade, is compact, has no loose parts, such as hammers and clappers, and is capable of being fixed permanently to the ship in the best position. While its audibility at a distance is as great as that of the bell, the sound it gives out is readily distinguishable. Extra value is given to the equipment by the fact that it is capable of emitting two notes, one high and the other low. Thus distinctive sounds may be made, the Morse alphabet used, or the name of the vessel announced.

PETTERS LTD.

A wide range of oil engines designed for stationary, marine, and lighting services is displayed on the stand of Petters Ltd., of Westland Works, Yeovil. In the series of Atomic two-stroke airless-injection oil engines, which now comprises sizes from 5 B.H.P. up to 540 B.H.P., two examples are shown running. These include a four-cylinder 195 B.H.P. direct-reversing and cold-starting marine engine, and a two-cylinder 180 B.H.P. engine designed for industrial purposes, while the smallest of the series, a new engine of 5 B.H.P. output, is exhibited for the first time. The marine engine serves to show the single wheel control system, which consists of a single hand wheel mounted at the forward end of the engine, which enables all manœuvres, both ahead and astern, to be carried out by the attendant in a minimum of time. Demonstrations that the complete reversal from full ahead to full astern or *vice versâ* can be carried out in approximately four seconds are being given on the stand. The special means of governing is combined with a controlled fuel admission for starting and enables the engine to be worked smoothly over a wide range of speed variation, always remaining under the control of the governor. The principle of the single-wheel control system for starting and manœuvring was fully described in our issue of February 20th, 1930, but the engine shown at Olympia embodies the firm's newest practice both in design and manufacture. It has a designed output of 195 B.H.P. at 375 r.p.m., with 10in. bore cylinder and 14½in. stroke.

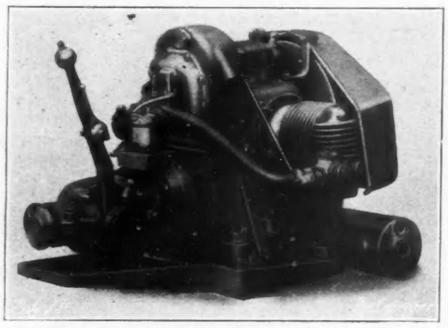

FIG. 13—4 B.H.P. MARINE PETROL ENGINE —PETTERS

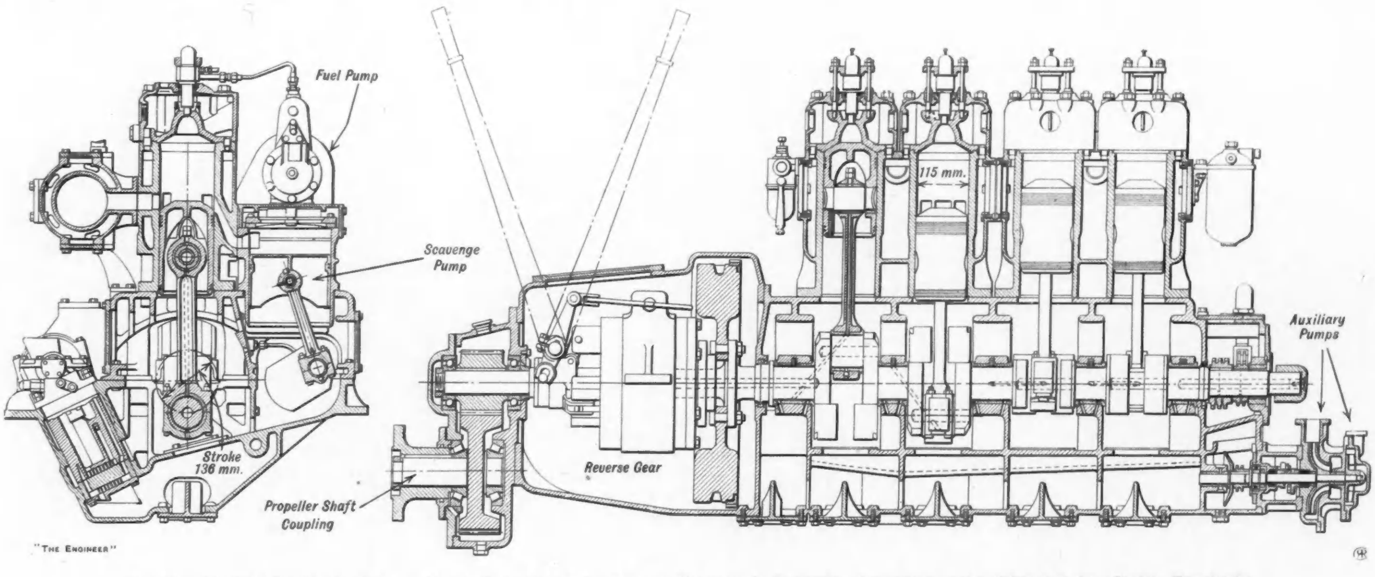

FIG. 14—40 B.H.P. HIGH SPEED TWO-STROKE C.I. ENGINE WITH GLENIFFER REVERSE AND REDUCTION GEAR—PETTERS

A special feature of the 180 B.H.P. two-cylinder engine is the improved water-jacketed cover for the cylinder head. The upper portion of the jacket is made of steel, and is so constructed that it can be easily and quickly removed to give free access to the water spaces in the cylinder head. In districts in which the cooling water is hard and there is a tendency towards "furring up," or in muddy estuary waters, the new type of head which has been adopted in all the larger engines has been found to possess many advantages. The fuel atomisers are also arranged in such a way that the area in the cylinder heads around the nozzles is well cooled, thus minimising the possible formation of carbon deposits on the injection nozzles.

Another exhibit of interest is the new two-stroke, four-cylinder, high-speed compression-ignition engine, which is shown in section in Fig. 14 and complete with a Gleniffer reverse and reduction gear in Fig. 29, page viii. It has an output of 40 B.H.P. at 1000 r.p.m. and a cylinder bore of 115 mm. with a stroke of 136 mm., operating on the two-stroke airless-injection principle with Bosch fuel injection pumps and nozzles. As will be seen from the drawing, the engine is of the separate scavenge pump type, which eliminates crank case compression. The neat arrangement of the scavenge pump chain drive is notable, and the strongly ribbed crank case and the engine-driven auxiliary pumps can be seen in the drawing. The fuel pump is mounted on the top of the scavenge air casing and is also chain driven from the crank shaft. A standard governor gear with hand speed control is attached to the fuel pump. Alongside can be seen the twin air filters, which are of the Vokes pattern. The Gleniffer type reverse and reduction gear, which is shown in section in Fig. 14, is designed to reduce the running speed of 1000 r.p.m. to a propeller speed of 500 r.p.m.

In Fig. 13 we illustrate the new four-stroke 4 B.H.P. 1500 r.p.m. air-cooled marine type petrol engine, which has a cylinder bore of 65 mm. and a stroke of 82 mm. The cylinders are offset 180 deg., so that a large main bearing area is given. The self-contained drive and clutch gives a propeller speed of 750 r.p.m. Our engraving clearly shows the deep ribbing of the cylinder casing and head, and the cowling which deflects over the ribs the air current generated by the fly-wheel, which is furnished on the outer side with a series of turbine nozzles to which air is fed through the centre of the cowl cover. Extensive tests with this engine have shown excellent results under widely varying conditions. The elimination of water cooling with the necessity for a water circulating pump with the piping and controls certainly gives a considerable saving in weight. With this type of engine a Zenith carburetter and a B.T.H. magneto are employed, the fuel control lever being attached to the clutch handle by means of a Bowden wire connection.

Another new exhibit is the 1-kW automatic lighting set, working on the floating battery principle, which we illustrate in Fig. 15. It is also made in a 2-kW size. The plant comprises a Petter "Universal" air-cooled petrol engine working on the four-stroke principle coupled direct to a shunt-wound dynamo with special series coils for starting. When the dynamo has attained its ordinary speed, to give the correct voltage, the starting coils are cut out and the dynamo runs as a shunt machine suitable for battery charging. The voltage is controlled by a special governor connected in series with the load, which maintains a constant voltage within reasonable limits by varying the engine speed according to load.

The switchboard, which is shown in the upper part of Fig. 15, is of the wall mounting type and contains both a charge and discharge ammeter, a voltmeter, charge and discharge fuses, and a master relay for starting and stopping the plant, with a safety switch to prevent the battery from being over-discharged in the event of failure of the plant. The first few lights are taken from the battery, but upon the load reaching a certain predetermined point the set starts up and the dynamo takes over the load, thus relieving the battery. Provided the load demanded is not greater than the output capacity of the dynamo, the battery also receives a charge, which keeps it ready for carrying the lighter loads and again starting the set. When the load is reduced to a predetermined low point the engine stops, the light being again supplied from the battery.

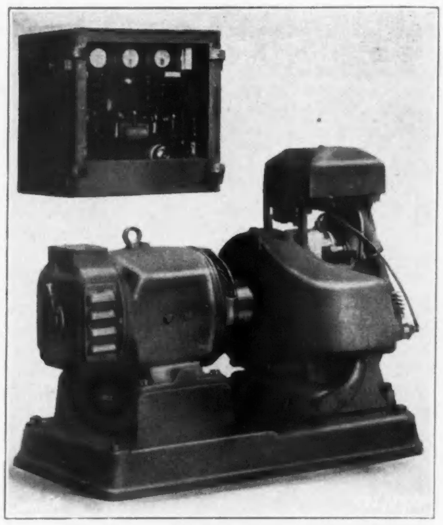

FIG. 15—1-kW LIGHTING SET—PETTERS

PHILIPS LAMPS, LTD.

Visitors interested in the use of X-rays in connection with engineering should not fail to inspect the exhibits of the X-ray and welding department of Philips Lamps, Ltd., of 145, Charing Cross-road, W.C.2. Simple and compact apparatus is shown for the examination of ship's plates and welds in steel up to ¾in. thickness. The use of the apparatus does not call for special skill, and, needless to say, the method is non-destructive. The apparatus is claimed to be invaluable in shipyards and in the testing department of engineering works. Mobile and stationary examples of the largest unit—the "Makro 200," with which 4in. of steel can be penetrated—are made for the examination of castings, forgings, riveted and welded boilers.

An exhibit of interest to metallurgists and works chemists is the Philips crystallographic equipment, which has brought X-ray crystal analysis within the range of the ordinary works laboratory. Like all the X-ray equipment made by the firm, it is completely shockproof and very compact. Pictures are also on view showing the results of X-ray tests on welds, rivets and castings.

Another exhibit is the rectifier welding set described in our issue of August 18th. The apparatus is smaller than a motor generator set of the same capacity, namely, 200 ampères, and as it operates from three-phase mains, it gives rise to a balanced load. A smaller set, working on the same principle, for welding thin plate, is also shown.

FOSTER INSTRUMENT COMPANY.

Among the indicating and recording temperature measuring apparatus shown by the Foster Instrument Company, of Letchworth, Herts, is a new multi-point recorder with a 7in. strip chart on which as many as six records can be produced, each printed in a different and clearly distinguishable colour. The instrument—shown in Fig. 16—is operated by an electric motor, through change-speed gearing, which enables the chart to be run at a suitable normal speed for production work or at a considerably higher speed for research purposes or for special batches of work demanding a high degree of temperature accuracy. Special automatic devices serve to lock all moving parts during transport and to protect the sensitive movement whilst the chart is being changed. Models of the "Introscope" for the detailed examination of the internal surfaces of tubes, rifle bores, high-pressure gas cylinders, &c., are also shown.

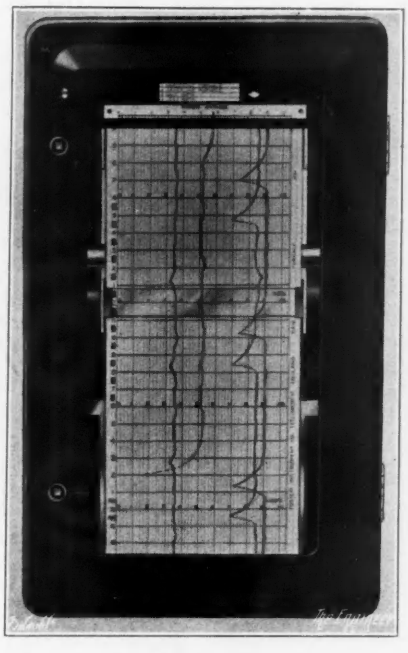

FIG. 16—MULTI-POINT TEMPERATURE RECORDER—FOSTER

L. GARDNER AND SONS, LTD.

Several engines of the high-speed variety are exhibited by L. Gardner and Sons, Ltd., of London and Patricroft, and also a three-cylinder 54 B.H.P. 400 r.p.m. heavy oil engine of the vertical marine type running on the two-stroke cycle. The high-speed engines comprise an eight-cylinder, giving 136 B.H.P. at 800 r.p.m.; a six-cylinder of 102 B.H.P. at 1700 r.p.m.; and a four-cylinder unit delivering 38 B.H.P. at 1000 r.p.m., all of which are adapted for marine use; and a $9\frac{1}{2}$ B.H.P. single-cylinder engine coupled to a dynamo and running at 1000 r.p.m. Although primarily designed for marine use, these engines are quite suitable for a number of other purposes, such as electricity generation, rail transport, ships' auxiliaries, and road transport. The engine illustrated in Fig. 32, page ix, is the six-cylinder, and the type in the makers' nomenclature is L.W. This engine is much used for road vehicle propulsion and many of its details have been specially studied from the point of view of a lorry driver. By the fitting of compression relief and inlet valve timing alteration devices it is claimed that to start the engine by hand is less arduous than to perform the same operation on a petrol engine. So easy is hand starting, in fact, that many lorries are not equipped with electrical gear. The engine has a cylinder bore of $4\frac{1}{4}$in. and a stroke of 6in. and the R.A.C. rating is $43\frac{1}{2}$ H.P. It is of the single-cell type and, according to the makers, has a fuel consumption of less than 0·380 lb. per B.H.P. per hour. The weight of the six-cylinder model under discussion, without dynamo or electric starter, is 150 lb. inclusive of the fly-wheel, so that it has a very low power to weight ratio. It will be noticed from the engraving that the cylinders are cast in blocks of three. For making up four-cylinder engines twin blocks are also made. The cylinder heads are made in blocks to correspond. There is, we think, no need to refer in detail to the design of the engine, which is, of course, constructed on sound principles in accordance with modern practice. As we have already mentioned the engine exhibited is intended for marine purposes. It is therefore fitted with a reverse gear.

THE NATIONAL GAS AND OIL ENGINE COMPANY, LTD.

The largest exhibit on the stand of the National Gas and Oil Engine Company, Ltd., of Ashton-under-Lyne, is a vertical six-cylinder "F A" type heavy-oil engine, designed to develop a constant output of 335 B.H.P. at 428 r.p.m. The cylinders have a bore of 11in. and a stroke of 15in., and at the full rated load the guaranteed fuel consumption is 0·39lb. per B.H.P.-hour. The bed-plate is a one-piece casting, which carries within it the crank shaft bearings, while the one-piece column which is bolted to it is bored to receive the loose liners. A feature of the cylinder covers is their deep section, which allows for the housing of the exhaust and air inlet valves, which have loose cages and operate directly over the pistons. The metal employed for the cylinder covers is a steel mixture of cast iron, incorporating cold-blast charcoal iron melted in a rotary furnace. Each cylinder has its own fuel pump, and the fuel valves are of the spring-loaded needle type. The fuel valve casing and seating is so designed that the cooling water is brought close to the seating and extends around the body of the atomiser, thereby ensuring a reasonable temperature for the fuel needle valve. There is a centrifugal governor of the crank shaft pattern, and a new feature which is specially useful for engines driving air compressors is the provision of a variable-range governor for controlling from half to full engine speed. Pressure lubrication is employed throughout. The lubricating pump is of the gear type, and is driven from the crank shaft by means of a chain. The engine is started on compressed air. Although a totally enclosed engine, special attention has been paid to the inspection covers, and doors, which give easy access to all working parts. They are of light weight and can be removed by one man. The range of engines represented by this example includes multi-cylinder units with five, seven, and eight cylinders, and, in addition, similar engines of the "B A" series provide a range from 240 up to 840 B.H.P.

Among the engines which are shown in operation we have specially chosen for mention the 120 B.H.P., six-cylinder vertical engine running at 800 r.p.m., which is illustrated in Fig. 27 on page viii. It differs in construction from that previously referred to, in that the valves are horizontally disposed in the cylinder heads, the air inlet valve being carried in a renewable cage, while the exhaust valve operates in a renewable guide, which is lubricated. The general construction of the cylinder head and the valve arrangement is illustrated in Fig. 18, which shows the valves of one of the smaller-powered engines, two of which will be shown in operation. In the case of the 120 B.H.P. engine, illustrated on page viii, a Bendix drive is used for starting, utilising the power from a small auxiliary engine through a belt drive. As an alternative a small compressed air motor may be employed.

The water circulating pumps and auxiliary bilge and deck-washing pumps are run at quarter engine speed, and are furnished when necessary with a disengaging clutch. The hand wheel shown at the end of the engine remote from the fly-wheel is for priming the lubricating oil system, and alongside it is an oil-pressure control valve. The air inlet manifold carries an air filter, and from it the air is delivered directly into the valve casing. Both the air and exhaust valve casings have removable covers. The engine is shown with an oil-operated reverse reduction gear-box, the standard reductions being 2 to 1 and $4\frac{1}{2}$ to 1. The clutch is furnished with operating and lubricating oil under pressure by a small gear-wheel type pump driven from the engine, and the manœuvring operation can be carried out by the finger light movement of the control cock, which can be arranged for remote control if desired.

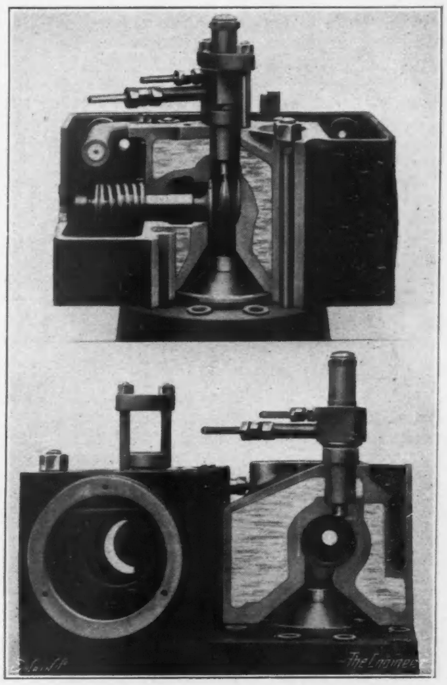

FIG. 18—CYLINDER HEAD AND VALVES—NATIONAL

In Fig. 17 we show a four-cylinder engine, one of two small marine oil engines also exhibited in operation, one of which has an output of 37 to 40 B.H.P. at 1000 to 1200 r.p.m., and the other, which is a two-cylinder unit of the same type, an output of $18\frac{1}{2}$ to 20 B.H.P. at the same speed. The four-cylinder engine is equipped with a patented spring starting device, which reduces any strain in starting up by hand. The engines we have referred to have shown good service at sea, especially in the fishing industry, and they are also being applied for lighting and auxiliary pumping on the Iraq petroleum pipe line installation.

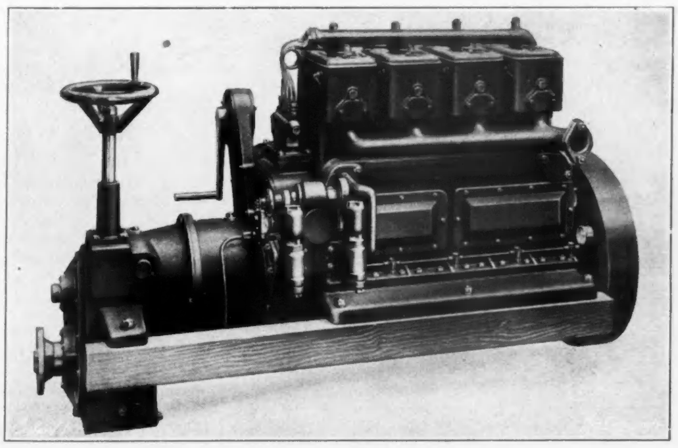

FIG. 17—37-40 B.H.P. MARINE OIL ENGINE—NATIONAL

THE ATLANTIC ENGINE COMPANY (1920), LTD.

The exhibit of the Atlantic Engine Company (1920), Ltd., of Wishaw, Scotland, comprises two examples of the company's high-speed oil engines, which are manufactured for marine propulsion, auxiliary lighting services, and for industrial driving.

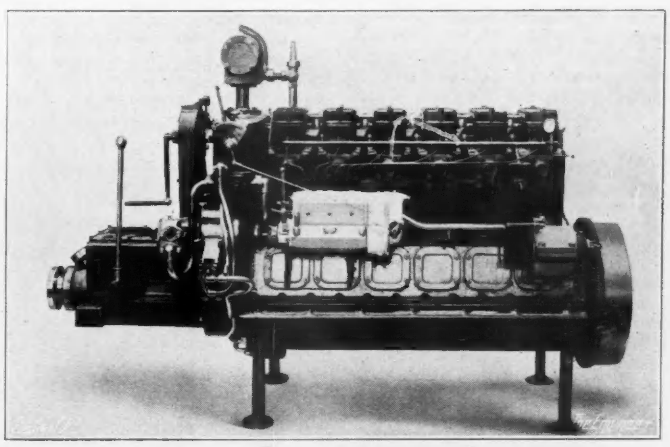

FIG. 19—55 B.H.P. MARINE OIL ENGINE—ATLANTIC

Both examples at Olympia are of the marine pattern, and are complete with plate clutch reverse gears of the company's own design. They are further arranged to illustrate three methods of starting, by electric starting motor, by air, or by hand. The accompanying illustration—Fig. 19—shows a six-cylinder engine which has a cylinder bore of 4½in. and 6in. stroke, and a designed output of 55 B.H.P. at 1000 r.p.m. The cylinders are of mono-block construction, and are made of a special close-grained cast iron. The liners are of centrifugal cast metal and are hardened. Drop forgings of high tensile steel are utilised for the connecting-rods, and the steel crank shaft corresponds to Lloyd's special requirements. In the case of the model we illustrate, both hand and electric starting is fitted. Two batteries of high power are used, which are designed also to meet the lighting services of the vessel in which the engine is installed. The other engine, a view of which is reproduced in Fig. 35 on page ix, is a four-cylinder, 70 B.H.P. unit, running at 800 r.p.m., with cylinders 6in. bore and a stroke of 8in. It is equipped with a compressed air motor starting arrangement geared to the flywheel, the air being carried in a receiver designed to have ample capacity for twelve starts. These engines represent types which have seen considerable service both at sea and on land, and have shown, we learn, a high degree of reliability in every respect.

The company also manufactures engines using petrol and paraffin fuels having a range of 5 up to 150 B.H.P. Many of these sets have been supplied for motor lifeboats and emergency lighting sets. The heavy-oil engines above referred to are built in standard units ranging from 24 up to 150 B.H.P.

ELLIOTT BROS. (LONDON), LTD.

Electrical and mechanical measuring and testing apparatus, of the indicating and recording types, for use in various industries is exhibited by Elliott Brothers (London), Ltd., of Century Works, Lewisham, S.E.13. The Siemens programme transmitter shown in Fig. 20 is used in conjunction with an automatic regulator and enables a definite and predetermined programme of operation to be followed in connection with manufacturing processes. If it is necessary, for example, that the temperature of a furnace shall first rise, then remain constant for a definite period, and finally drop at the end of the process, the apparatus may be employed to meet these conditions. It has been used for the control of annealing and carburising furnaces in the steel industry, for control in connection with drying and firing ceramics and porcelains, the treatment of cellulose in celluloid, and vulcanisation in the preparation of rubber. The mechanism, which controls the regulator electrically, consists of a number of cams cut in accordance with the required programmes and driven by a clock or an A.C. synchronous motor.

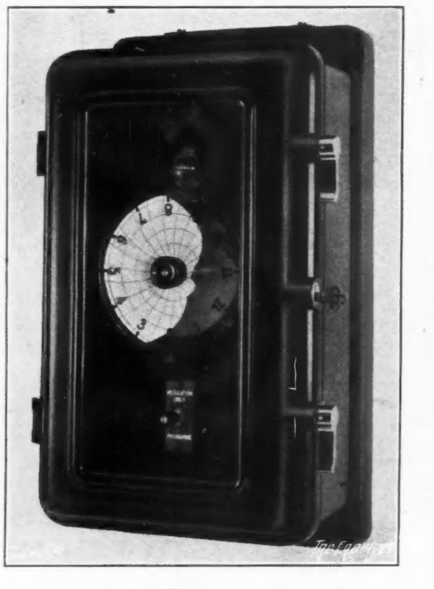

FIG. 20—PROGRAMME TRANSMITTER—ELLIOTT

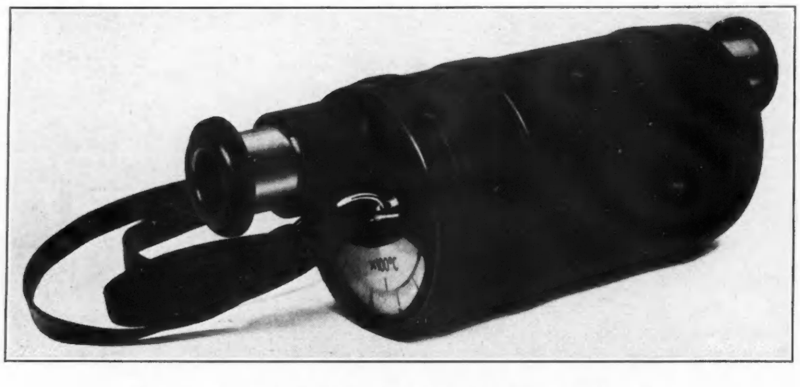

FIG. 21—OPTICAL DIRECT-READING PYROMETER—ELLIOTT

The Tollemache bin level indicator shown in Fig. 22 is used for indicating the level of the contents of a bin or bunker containing powdered or granulous substances. The instrument, which is only one of its kind, has been primarily designed for use with pulverised coal, but it can be employed to show the level in storage bins or bunkers of practically any powdered or granulous substance, such as chocolate, cement, grain, flour, or small coal or coke. The transmitter operates in conjunction with a signalling unit with a coloured lamp or lamps or a Klaxon horn, and may be part of the transmitter or a separate unit, placed in any convenient position. The pressure produced in the bin or hopper operates on a spring-loaded diaphragm attached to a plunger, the movement of which opens or closes a set of contacts which cause the signal unit to indicate when the predetermined level in the storage bins or hoppers has been reached or when they are ready for replenishing.

Another exhibit is a power factor finder and circuit analyser, shown diagrammatically in Fig. 23. The current coil comprises the field circuit of the wattmeter and is wound on a stator composed of iron stampings. Two moving coils rigidly connected together form a differential element, one moving coil being connected to a resistance and the other to a condenser. Across the combination a potential divider is joined, and across the terminals of this part of the apparatus the voltage of the circuit under test is applied. Assuming the power factor of the circuit is unity, then the travelling contact of the potential divider will have to be moved to point A on the potentiometer, since the current in E will then be zero and the current in D will be at 90 deg. out of phase with the flux due to the current circuit and will therefore exert no torque. The position of balance must then be at point A. For any other power factor within the range of the instrument the contact of the potential divider is moved along to some point between A and B until a new balance is obtained. By marking against the various points of balance equivalent power factors a direct-reading scale of power factor is obtained. If in one position of the change-over switch balance cannot be secured the switch should be reversed. If the power factor under test is beyond the range of the instrument balance is unobtainable with the switch in either position. In analysing the power factor of a three-phase circuit the power factor of each phase is measured in turn, and by noting the current the vector relationship can be laid out. If, at the same time, the voltage is noted, then the kilowatts can also be obtained.

The instrument shown in Fig. 21 is a new type of optical direct-reading pyrometer self-contained in a small portable case. It is known as the Siemens cross-filament pyrometer, and the principle involved is that of maintaining the filament of an electric lamp at a known constant temperature and reducing the incoming radiation of the hot body under test until the filament disappears into the background. The reduction of radiation is obtained by the interposition of a wedge-shaped graduated absorption screen calibrated in terms of temperature between the standard lamp and hot body.

The method of obtaining and maintaining the standard lamp temperature is ingenious. Actually the lamp has two filaments crossing each other and consisting of a ribbon and wire flattened at the junction point. The filaments, which are connected in series, are composed of two materials having diverse temperature-current characteristics and are supplied with current by a battery incorporated in the instrument through an adjustable resistance. The two filaments are equally brilliant at one particular temperature, which is easily obtained by adjusting the resistance. For short-duration readings the battery incorporated in the instrument is sufficient, but for longer tests a plug and socket are provided to enable an accumulator to be used. The cross filaments and observed object can be sharply focussed by the position of the lenses. Instruments are available for temperatures of 800–1500 deg. Cent. and 900–1800 deg. Cent. As none of the parts are in actual contact with the furnace, deterioration is eliminated. Other exhibits consist of a frequency recorder, speed indicators and recorders, current transformers, &c.

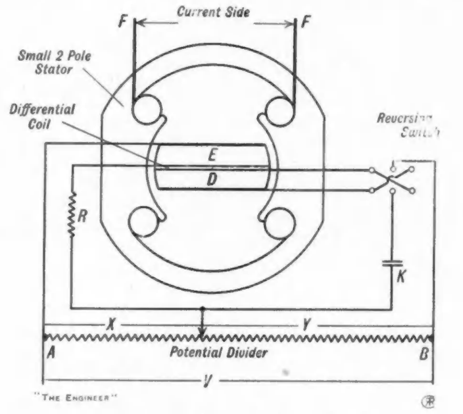

FIG. 23—POWER FACTOR FINDER—ELLIOTT

HANCOCK AND CO. (ENGINEERS), LTD.

It must have become almost a habit among engineers interested in flame cutting machines to go straight past other stands in the Exhibition to that taken by Hancock and Co. (Engineers), Ltd., of Croydon, for almost without fail some new machine or other device is to be seen here at each biennial exhibition. This year two devices are attractive. Firstly, there is the improved type of machine known as the "Simplex" universal, which we illustrate in Fig. 24; and secondly, there is the portable "Auto" cutting machine. To take the "Simplex" model first, unlike the U arm type, this machine has the work piece on one side of the centre and the template or drawing table on the other. The tracer head is fixed to a carriage upon which is also mounted the burner on an extended arm. This carriage is able to run for the full width of the machine on two tubes, which, being mounted on wheels at each end, are able to move back and forth on rails. To keep the tubes in axial alignment coupled pinions at each end engage with racks in the rails. Automatic straight line cuts, vertically or at a bevel, can be made parallel to the axes of the machine and, if required, two cutter heads can be fitted to allow dual regular or irregular cutting to be carried out from one template or drawing. In addition, circles may also be cut automatically. In conjunction with the universal tracer head a reversible table makes it possible to change over from template to drawing operation in a few seconds. The tracer head has three interchangeable forms of drive: directly from a drawing; from a template of strip aluminium; or from a wooden template. All the controls for the gas, heating, and cutting oxygen, starting and stopping and reversing the motor, and vertical adjustment of the burner can be operated from either the front or the back of the machine, while the cutting speed in inches per minute is shown by a speed indicator mounted on the tracer head.

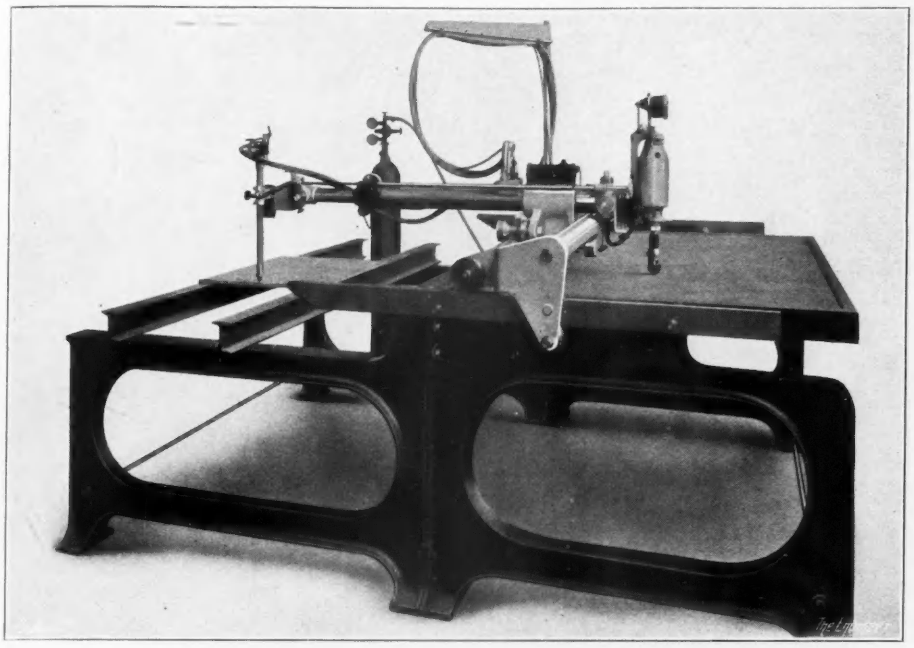

FIG. 24—"SIMPLEX" UNIVERSAL CUTTING MACHINE—HANCOCK

The other machine to which we have referred is illustrated in Fig. 25. It is particularly suitable for shipyard work and the like and is shown for the first time. For straight cutting the machine is fitted with two spring guide wheels which normally engage with a 1½in. angle guide or similar device. Bevels up to 35 deg. may be cut by swivelling the head. Additional usefulness is given to the device by the provision of a radius bar, which may be fitted on either side. The machine may thus be made to rotate round a centre held in position by means of a spring-operated centre point. Circles from 2in. radius upwards may be cut. As will be seen from the drawing, the driving motor is enclosed within the main body. It can, however, easily be removed, and since it is connected up by means of plugs and sockets, no electrical connections need be disturbed by the operation. If required, the direction of rotation of the motor may be reversed. From the motor the drive is taken through worm and worm wheel reduction gearing to the front shaft to drive directly the wheel nearest the burner. In order to obviate the disadvantage of driving both wheels directly, an arrangement which would cause the machine to have a tendency to run straight when hand guided, a friction device is placed between the driving shaft and the other wheel. This clutch may be adjusted to be free, partially locked, or completely locked. Thus when the machine is hand steered, slip at the clutch occurs when rounding curves. A copper-asbestos shield protects the nearer driving wheel from sparks emanating from the burner. Control is effected from a grip handle. The first grip opens the heating oxygen and the second starts the motor and turns on the cutting oxygen. A dial in the top of the box-shaped aluminium body records the travelling speed in inches per minute. As will be seen from notes on the drawing, the burner has a 1½in. transverse movement on the slide and the height of the burner from the plate may be adjusted.

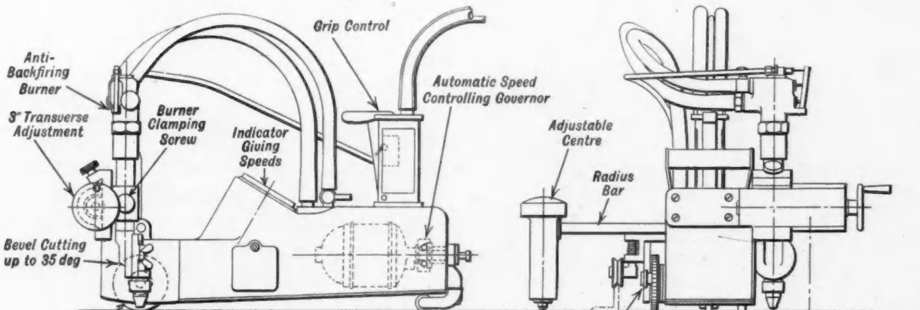

FIG. 25—PORTABLE "AUTO" CUTTING MACHINE—HANCOCK

THE TURBINE FURNACE COMPANY, LTD.

In bringing to our notice its exhibit at Olympia the Turbine Furnace Company, Ltd., of 238B, Gray's Inn-road, London, states that every job with which the firm comes into contact in this country requires special consideration of the various factors involved. For instance, at collieries and works situated near collieries a type of furnace such as the steam jet forced draught with extension grate, suitable for burning the low-grade fuel with high ash content cheaply available in such districts is called for, whereas it is futile to transport such a high proportion of ash to centres far removed from collieries, and a furnace suitable for the use of good or washed fuel is then required. In the firm's experience fan forced draught, either with hand or mechanical stoking, can on ordinary standard boilers be expected to give an all-round efficiency of 70 per cent. The firm's exhibit is a full-size Lancashire boiler front. The left-hand flue is fitted with a furnace and extension grate arranged for machine firing by sprinkler stoker and fan forced draught; and the right-hand flue has a standard furnace arranged to suit a marine boiler with steam jet forced draught. The line engraving reproduced in Fig. 26, although actually referring to an installation on the s.s. "Cormorant," is exactly the same in all particulars as that shown at the Exhibition. The fire-bars have forwardly inclined blades, which deflect the air through the air spaces with the minimum of resistance and, together with the diminishing cross-sectional area of the troughs, reduce the amount of steam or power required for forced draught. For a typical Lancashire boiler evaporating between 9000 lb. and 10,000 lb. per hour a figure of 2 H.P. is given by the makers for this service. According to figures the makers have obtained as a result of six months' working on a number of small steamers, the tonnage of low-grade fuel burned in the furnaces supplied is no greater than that of better quality fuel consumed on ordinary bars under natural draught conditions.

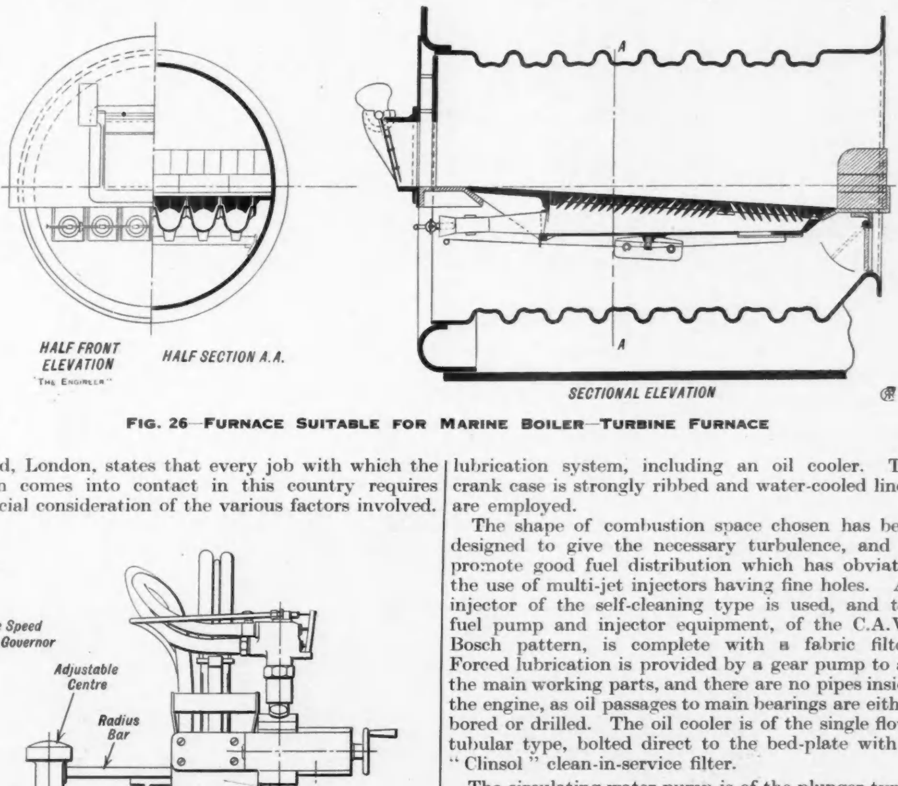

FIG. 26—FURNACE SUITABLE FOR MARINE BOILER—TURBINE FURNACE

J. SAMUEL WHITE AND CO., LTD.

Oil-firing equipment for boilers and furnaces on the mechanical jet pressure system forms the principal exhibit on the stand of J. Samuel White and Co., Ltd., of Cowes, Isle of Wight. The main exhibit is a pressure oil pump and heater, with suction and discharge strainers, complete with a hand pump for lighting purposes, the whole equipment being designed for use with furnace fronts, fitted with pressure-type oil burners. Various patterns of furnace fronts are illustrated.

The type of burner used is, it is claimed, specially useful for lighting up purposes, as it will burn cold oil. An interesting type of burner carrier is also shown, which enables burners to be quickly withdrawn and replaced; a safety hook cutting off the oil supply before the burner can be taken out.

The firm is also showing a four-cylinder, cold-starting marine type oil engine working on the compression-ignition principle, which is complete with reverse gear. It is illustrated in Fig. 30 on page viii. It is rated at 24 B.H.P., 1000 r.p.m., and has a fuel consumption of 0·45 lb. per B.H.P.-hour. It is totally enclosed and works with a pressure-feed lubrication system, including an oil cooler. The crank case is strongly ribbed and water-cooled liners are employed.

The shape of combustion space chosen has been designed to give the necessary turbulence, and to promote good fuel distribution which has obviated the use of multi-jet injectors having fine holes. An injector of the self-cleaning type is used, and the fuel pump and injector equipment, of the C.A.V.-Bosch pattern, is complete with a fabric filter. Forced lubrication is provided by a gear pump to all the main working parts, and there are no pipes inside the engine, as oil passages to main bearings are either bored or drilled. The oil cooler is of the single flow, tubular type, bolted direct to the bed-plate with a "Clinsol" clean-in-service filter.

The circulating water pump is of the plunger type, and is mounted on the crank case, but is so arranged as to prevent any water from contaminating the lubricating oil. Starting is effected by hand with the aid of a tinder cartridge or electric plugs.

The reversing gear incorporates ahead and astern multi-plate clutches, and is mounted upon an extension of the engine bed-plate and crank case. It is of the epicyclic spur wheel type, with pinions running in self-aligning ball bearings. Heat-treated steel is employed for the gearing, and the use of ball bearings has reduced the number of bushes to a minimum. The gear is fully lubricated from a passage in the crank shaft, which is fed from the main pressure oil supply. Models and photographs of vessels constructed by the firm, including naval, commercial, and pleasure craft, are also shown.

Negretti and Zambra.

As usual, upon the stand taken by Negretti and Zambra, of Holborn-viaduct, London, there are exhibited various instruments for a very wide range of purposes. The number of different instruments manufactured by this firm is indeed almost bewildering in its variety, although the number of principles on which they are all built is comparatively small. Out of such a display it is a matter of some difficulty to make a choice. Prominent, of course, is the mercury in steel dial thermometers, well known to many besides actual users of the firm's products. These instruments are suitable for a very wide range of temperatures, and it is claimed that the direct-action movement and the "micro-bore" capillary construction, together with other devices, eliminates or renders negligible all errors due to friction, back-lash, hysterisis, barometer variation, bulb level, and vibration. In view of the widespread knowledge of their construction, a description of a typical instrument is not called for. Operating on the same principle, however, the firm has recently produced the "Mersteel" recording thermometer, illustrated in Fig. 38. It has been designed to give at a lower price an accuracy and reliability comparable with older designs. It takes a chart 9½in. in diameter and has a pen travel of 4in. The chart may be graduated to any standard range, and may be suitable for daily or weekly records. A moisture and fume-proof cast iron case carries the rustproof movement within. As may be noted from the engraving, the instrument can be supplied with two pens if desired.

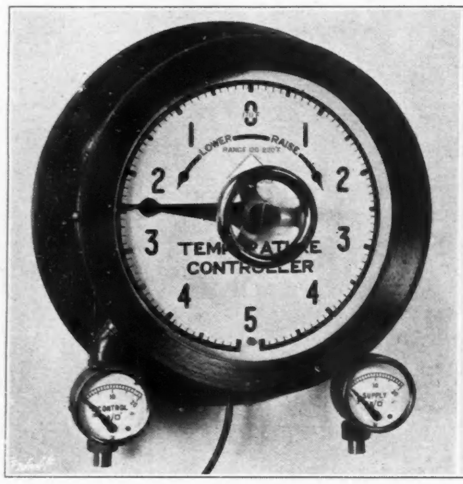

Fig. 37—Temperature Controller—Negretti

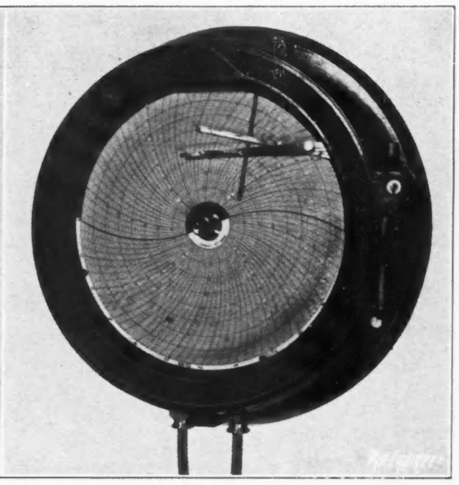

Fig. 38—Recording Thermometer—Negretti

Space precludes any lengthy mention of many of the other exhibits shown on the stand. Numbers of electrical thermometers, recording thermo-couple pyrometers, humidity controllers, and boiler-house instruments are to be seen in various mountings. One of the most interesting devices is the temperature controller illustrated in Fig. 37. The principle on which it acts is shown diagrammatically in Fig. 39. Main control is obtained from a mercury-in-steel thermometer, the movements of which, however, are not directly concerned in altering the supply of fuel to the heating burner. For this purpose compressed air at a pressure of 15 lb. per square inch is utilised. Each controller requires about 0·5 cubic feet per minute for its satisfactory operation. Referring to Fig. 39, the main fuel supply pipe is shown at the bottom and the temperature controller E at the top. The compressed air is admitted to the pipe J through a restriction valve C. Should the temperature to be controlled vary, the bourdon element H of the thermometer, of which the bulb is shown at G, alters its position, thereby altering the setting of a leak valve E and causing the air pressure in the pipe line J to rise or fall. This air pressure acts upon the diaphragm which controls the opening of a valve in the fuel supply pipe, and its alteration thereby causes a change in the rate of supply of the fuel. Since the leak valve E can be adjusted to give a fine throttling action, periodic peaks of temperature are avoided. Two air pressure gauges are fitted to the instrument showing respectively the inlet pressure and the pressure in the pipe line J. Besides those mentioned, many other instruments are to be seen on the stand.

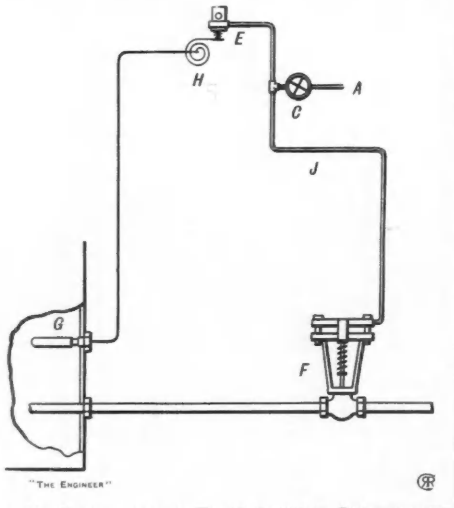

Fig. 39—Operation of Temperature Controller

The Stream-Line Filter Company, Ltd.

Upon the stand taken by the Stream-Line Filter Company, Ltd., of 45, Horseferry-road, London, there is a very interesting portable filter set similar to that illustrated in Fig. 41. Another of the same type is mounted on castors. These portable sets are intended for filtering, de-hydrating, and de-aerating the insulating oil of transformers and other electrical equipment, and the arrangement of the various parts within the plate metal casing mounted on the trolley is shown diagrammatically in Fig. 40. Two cocks, suitable for the reception of hoses, are mounted on one side of the outfit, and provide for the inlet of dirty and the outlet of cleaned oil respectively. From the inlet cock the dirty oil is admitted to a chamber containing an electric heater. This latter is provided with tubular immersion elements of ample capacity controlled by triple-pole switches in groups of three, and serves to raise the oil to a temperature of 60 deg. to 80 deg. Cent. From the heating chamber the oil is drawn by an oil pump, which delivers at a steady rate into the filter chamber. As engineers will be well aware, the filter made by the Stream-Line Filter Company employs the principle of edge filtration between paper discs mounted on rods and maintained under suitable compression by end loading. When liquid is forced between the papers from the outside to the inside, all traces of solid and even colloidal carbon from switches, it is claimed, are retained at the edges, so that the liquid, in this case oil, passes onward absolutely clean. The solids, of course, build up as a cake on the outside of the filter columns, and are easily removed by reversal of pressure as will be described later. As the papers are cleaned without removal, the same packs last for many years. The possibility that loose fibres might be carried forward by the oil is removed by a suitable "running in" period in the manufacturer's works. Having passed through the filter, the now clean oil enters a vacuum chamber. Here it falls over a series of shallow trays dripping down from one to the next. A certain degree of moisture has already been removed from the oil in passing through the filter in layers of molecular dimensions. In the vacuum chamber the temperature of the oil is well above the boiling point of water, corresponding to the vacuum, and consequently the last traces of moisture are removed. Together with air and gases also removed from the oil, owing to the low pressure, the moisture is drawn out of the top of the receiver by a dry pump of the vacuum type. The cleaned and renovated oil, meanwhile, is withdrawn from the bottom of the chamber by a special pump, the rate of delivery of which is controlled by a float valve in order to maintain an adequate level of oil in the chamber. Although shown separated in the diagram, the two oil pumps and the vacuum pump are all mounted together on a convenient bed-plate and driven by a single motor. The plant, it will be seen, can be operated continuously, and having cleaned, dried, and de-aerated the oil, delivers it without exposure to the atmosphere to whatever place it may be required. It remains to be described how the pressure is reversed for cleaning the filter columns. It will be noticed in the diagram that there are four three-way cocks controlling the flow at various points. It should also be noted that the vacuum pump is adaptable to work as a compressor. Before shutting down the plant after a spell of work, the position of the cock A is reversed, so that the atmosphere is put into connection, not only with the interior of the vacuum receiver, but also with the suction side of the vacuum pump. At the same time the air delivered by the vacuum pump cannot escape from the air bottle, since the passage through cock A is now blocked. Consequently, an air pressure is built up. Concurrently, the filter chamber is drained of unfiltered oil by turning cock B to open it to atmosphere, the connection with the vacuum chamber being by the same operation broken. So soon as sufficient pressure has been built up in the air bottle, the cock C is turned to interconnect the air bottle with the discharge side of the filter chamber. As a result, air is blown through the filter in the reverse direction, and the cake of solids is thereby removed to drain with the remnant of the unfiltered oil as a sludge out of the chamber. Cock D, which has so far remained unmentioned, is made use of when starting up to re-circulate the oil in the heating chamber until a sufficient degree of temperature has been attained for the plant to be put on continuous operation.

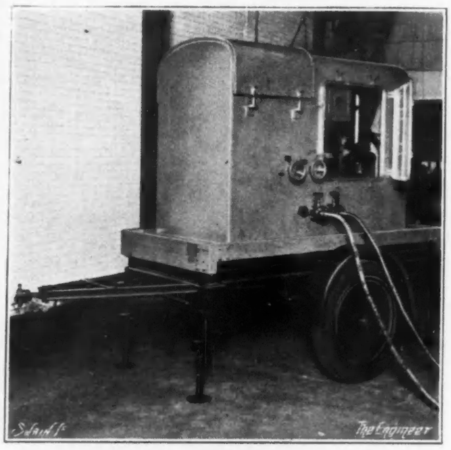

Fig. 41—Portable Filter—Stream-Line

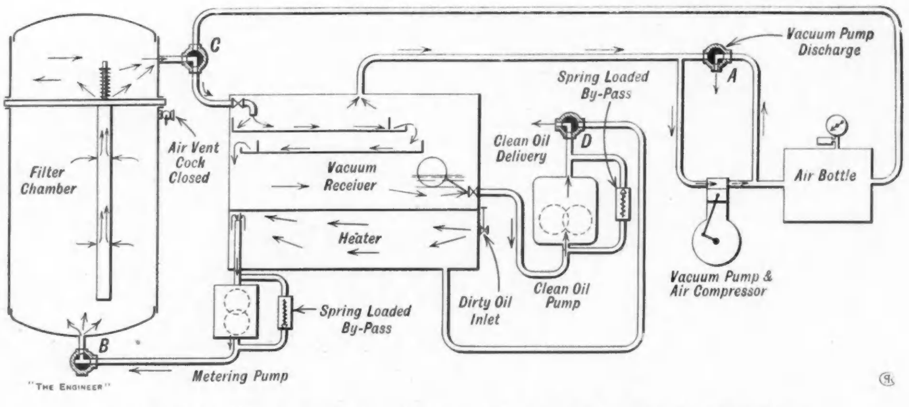

Fig. 40—Diagrammatic Arrangement of Portable Filter—Stream-Line

Besides the plant just described, the firm is on this occasion making a special exhibit of devices for direct attachment to engine lubricating systems, as distinct from the self-contained type, which deals with batches of oil quite apart from the engine. Some time ago a distinct preference was shown for the latter arrangement, but we are informed by the makers that there has been a gradual growth of favour for the attachment type of recent years.

A range of six such plants suitable for engines of 50 to 1500 B.H.P., and capable of by-passing 2 per cent. of the oil in circulation per hour, is therefore being shown.

W. KENNEDY.

Tube and bar bending machines in several sizes and types are exhibited by W. Kennedy, of West Drayton, Middlesex, and we have chosen for illustration in Fig. 42 one of the smaller machines utilising direct leverage. It is suitable for bending, cold and unloaded, wrought iron gas, steam and water tubing up to 1in. bore. With suitable formers brass, copper, and steel light-gauge tubing may also be bent, while work upon angles, tees, channels, &c., is within its capacity if special formers are provided. The principle of operation is very simple. Upon the main body or base there is screwed an adjustable top plate. One of the former rings is placed between the top plate and the base and the tube is bent around it by the use of a lever placed in one of the holes provided in the bending arm. Instead of a bending block a suitably shaped roller is used. Owing to the tendency of the work to expand laterally when being bent, the top plate becomes tightly fixed. In order to unscrew it, therefore, the bending arm is swung back until the pin to be seen in the engraving drops into one of the holes in the plate. The full leverage of the arm may then be used to loosen it. Larger machines made by the firm utilise a gear and ratchet principle to increase the leverage available. Machines suitable for bending still heavier material are operated through a worm and wheel mechanism.

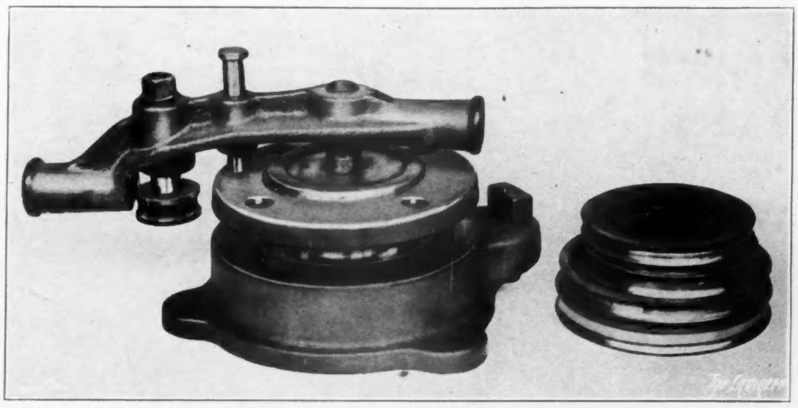

FIG. 42—TUBE BENDING MACHINE AND FORMERS—KENNEDY

J. G. SMITHSON AND CO., LTD.

Industrial motor controllers of the contactor type with new mechanically operated contactors are being exhibited in sizes ranging from 5 to 100 horsepower and suitable for A.C. or D.C. supplies by J. G. Smithson and Co., Ltd., of Nelson House, Moorstreet, Birmingham 5. The contactors are mounted on an insulated panel inside the controller, as shown in Fig. 43, and are operated by a camshaft directly coupled to the crank handle. The contacts are made of "Steb" metal, consisting of a copper base with a heavy silver face sweated and rolled in, the circuit being made and broken on the silver faces alone. Water and dust-proof cases protect the working parts and the general design complies in every way with the applicable B.S.I. specifications.

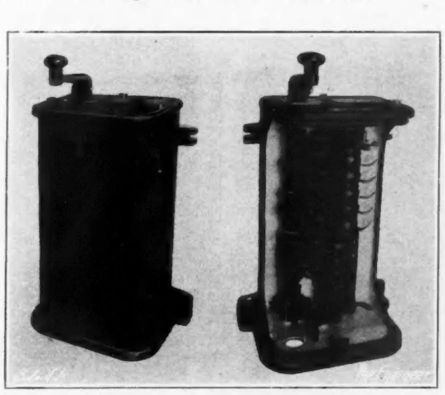

FIG. 43—INDUSTRIAL MOTOR CONTROLLER

Battery vehicle and light-weight trolley omnibus controllers are shown. The latter is a direct-acting contactor controller with eight notches for plain-series resistance or tapped field control. The contactors are trigger operated by an "over-centre" motion and are closed by means of a simple lever coupled directly to the foot pedal. As no cams or ratchets are employed, the mechanism is free from complications. Motors with capacities up to 150 horse-power at 600 volts can be controlled, the continuous rating of the trigger-operated contactors being 200 ampères. It is said to be impossible to open or close the contactors slowly even if a deliberate attempt be made to do so. Like the contacts on the industrial controllers, those on this trolley omnibus apparatus are composed of "Steb" metal and the circuit is made and broken on the silver faces.

The arc shields and blow-out coils are mounted together as single unit, which is pivoted at the top. By undoing two nuts this unit can be swung clear of the contacts, which can then easily be inspected without interfering with the connection to the blow-out coils. A separately mounted foot pedal, which can be fixed in any position convenient to the driver, serves for operating the controller, and although there is no difficulty in deciding when a notch has been passed, the pressure required to operate the apparatus is small. The total weight is only 112 lb. and the complete unit is neat and compact. A separately mounted drum type switch, electrically interlocked with the main controller, serves for reversing the motor.

THE LIVERPOOL REFRIGERATION COMPANY, LTD.

With a view to meeting the demand that is believed to exist for small horizontal oil engine-ammonia compressor sets the Liverpool Refrigeration Company, Ltd., of Colonial House, Water-street, Liverpool, together with Tangyes, Ltd., of Birmingham, has brought out the set illustrated in the accompanying engraving, Fig. 44. It is claimed that such a combination set will show a saving in fuel and initial costs over the more usual motor-driven refrigeration compressor, and that although it takes up slightly more deck space, it can be accommodated in a 'tween deck as easily. The actual capacity of the set exhibited is 20 tons refrigeration on a gas cycle of 5 deg. Fah. and 86 deg. Fah.—equivalent to 240,000 B.Th.U. per hour—and the floor space required is 8ft. by 10½ft. by a height of 4ft. 6in. The compressor is of the double-acting type with suction and delivery valves of the ring plate variety fitted in the back cover and readily accessible. Access to the cast iron piston and the interior of the cylinder is gained by the removal of the back cover, complete with its valves, and without disturbing any of the connecting piping. By altering the position of the slipper type crosshead the piston clearance can be adjusted. The compressor is driven by a single-cylinder Tangye oil engine developing 39 B.H.P. at 270 r.p.m. and coupled to the compressor through a heavy fly-wheel. The speed may be reduced to 140 r.p.m., if required, while the engine is running. The Tangye system of super-compression which we have described on previous occasions is fitted to the engine for use when starting.

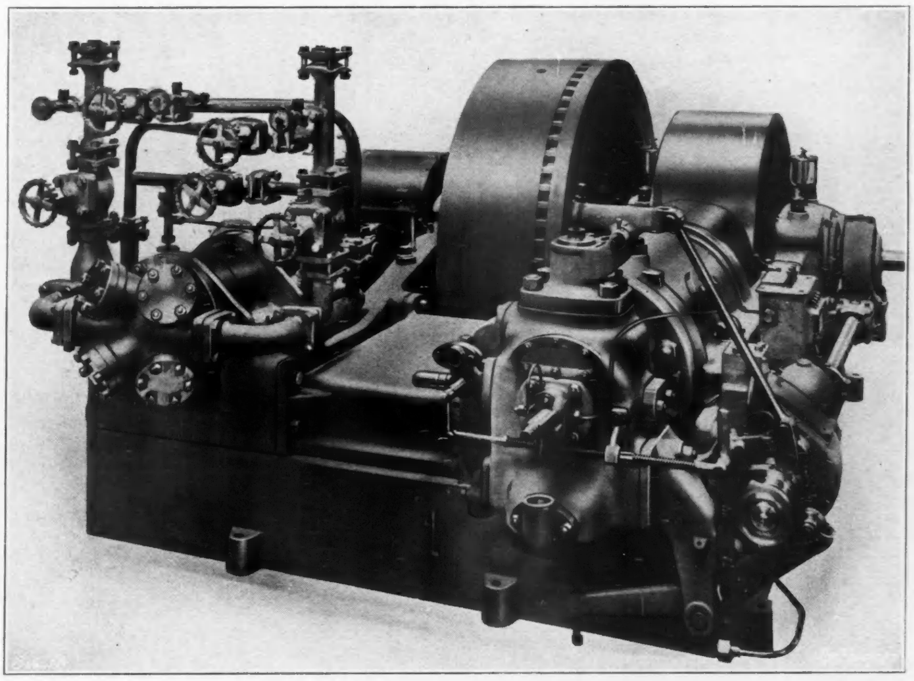

FIG. 44—HORIZONTAL OIL ENGINE - AMMONIA COMPRESSOR SET—LIVERPOOL REFRIGERATION

THE SPIRAL TUBE AND COMPONENTS COMPANY.

The Spiral Tube and Components Company, of King's Cross, London, and of Derby, has as one of its chief exhibits a combined water and oil cooler for oil-engine locomotives. Both elements are cooled by a single high-efficiency fan, which is driven at low speed by a double "V" belt. The fan spindle is provided with a belt-tensioning device. The accompanying illustration shows the back view of a cooler suitable for engines of from 200 to 250 H.P., and is representative of a range designed for engines of 100 to 600 H.P. Under normal climatic conditions it will dissipate 360,000 B.Th.U. per hour from the water, and 36,000 B.Th.U. per hour from the oil, the capacity of other sizes of coolers being in proportion. The whole of the cooling tubes and fins are made of copper in order that the efficiency may be maintained over a long period. Spiral copper fins or gills arranged to give maximum turbulence and minimum air resistance are wound on both sets of tubes, those for the oil cooler being still further provided with spiral internal baffles to promote oil turbulence. These baffles also act as oil cleaners,

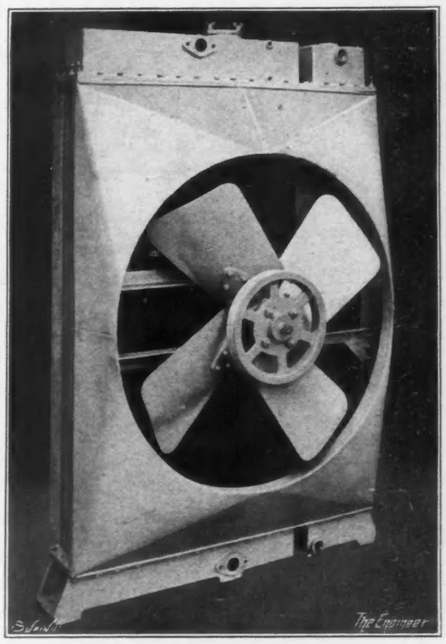

FIG. 45—COMBINED WATER AND OIL COOLER —SPIRAL TUBE

since they can be withdrawn, wiped, and replaced on removal of the top header. The fact that the guaranteed power consumption of the fan is less than 3 B.H.P., or only 1·2 per cent. of the higher engine output for which the cooler is designed, indicates the efficiency of the cooler.

Other exhibits on this stand include water coolers for internal combustion engines, Plenum type heaters for cinemas, public buildings, and for producing hot air for industrial processes up to a temperature of 370 deg. Fah.; unit heaters for garages and factories by means of which warm air is deflected to the ground level by means of electric fans; oil coolers operated by water; and copper spiral gilled cooling coils for refrigerating plants.

Crossley Brothers, Ltd., and The Premier Gas Engine Company, Ltd.

The largest working oil engine in the Exhibition is to be seen on the stand of Crossley Bros., Ltd., of Manchester. It is a Crossley-Premier horizontal *vis-à-vis* eight-cylinder four-crank marine oil engine, shown by the Premier Gas Engine Company, Ltd. (Crossley Brothers, Ltd.), of Sandiacre, near Nottingham. A view of the engine is reproduced in Fig. 31 on page viii. Its rated output is 600 B.H.P. at 300 r.p.m., or, when supercharged by an electrically driven blower, 750 to 800 B.H.P. at the same speed. The engine is of particular interest, as it is an exact duplicate of that supplied for the electrical propulsion of an electric ferry boat which has been built at the yard of the South China Motor Shipbuilding and Repairing Works, Hong-Kong, for the Star Ferry Company's Hong-Kong-Kowloon service. The normal rating of the ferry boat engine is 500 B.H.P. at 270 r.p.m., and 575 B.H.P. at 300 r.p.m. under overload conditions. It is coupled direct to a 300-kW B.T.H. generator, which delivers current to two 370 B.H.P. motors mounted on the propeller shaft, one at each end of the ship. The generator and the motors are controlled from the bridge. Drawings of this ferry boat were published in The Engineer of December 30th, 1932.

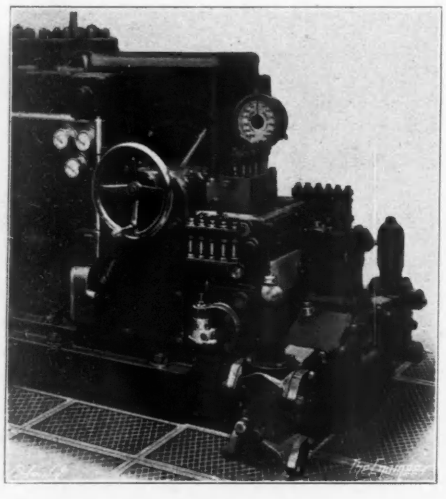

FIG. 46—CONTROL END OF 150 B.H.P. ENGINE—CROSSLEY

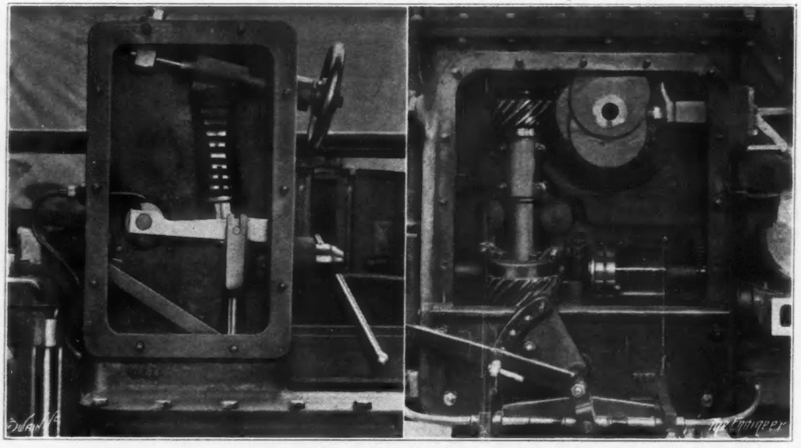

FIG. 47—SPEED ADJUSTING AND GOVERNOR GEAR—CROSSLEY

As the speed control arrangements of the engine are of particular interest we show in Fig. 47 two views, one of the governor on the side shaft and the other of the hand-operated speed adjusting gear. The governor is arranged on a vertical shaft which is driven direct from the crank shaft and is of the vertical spring-loaded type. The movement of the governor is transmitted by a side rod to a series of wedges on the fuel pumps, which by controlling the opening of the fuel pump by-pass valves regulate the fuel delivered to the cylinders in direct proportion to the load requirements. The light cams which are seen to the right of the governor spindle are for the indicating gear motion.

A Crossley engine of outstanding interest is a new six-cylinder two-stroke direct-reversing vertical marine engine with a scavenge pump mounted at the forward end of the bed-plate. It is illustrated in Fig. 36 on page ix and a view of the starting controls and auxiliary pumps is reproduced in Fig. 46 herewith. This engine is built in units of three to six cylinders and the output of the engine exhibited is 150 B.H.P. at 450 r.p.m. As will be gathered from our illustration, the whole structure is very rigid, the monobloc type crank case being bolted direct to the girder pattern base-plate, the thrust block being mounted on an extension of the bed-plate at the fly-wheel end. The cylinders are separate units and are interchangeable. Large inspection doors are provided, giving access to all running parts. The scavenge pump is operated directly from the crank shaft. As the scavenge air is delivered directly into the manifold serving all the cylinders, and a non-return valve is fitted to each cylinder, any possibility of the exhaust gases blowing back into the inlet air manifold is avoided.

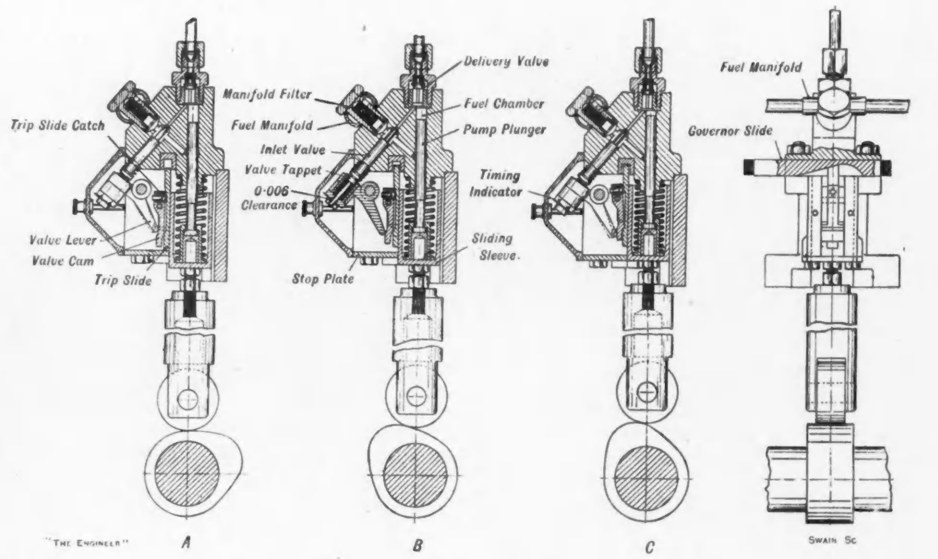

FIG. 48—OPERATION OF FUEL PUMP—BLACKSTONE

The grouping of the controls, fuel pump, tachometer, mechanical lubricators, auxiliary pumps, and air compressor for starting and manœuvring air is clearly indicated in Fig. 46. The governor controls the engine speed over the complete range down to one-quarter speed, and direct reversing is carried out in the usual way by a single hand wheel, the rotation of which brings the ahead or astern set of cams into position as required. The main parts of the engine are all lubricated under pressure and the system is fed by two ram type pumps. The provision of a separate scavenge pump not only gives, it is claimed, good scavenging with a charge of cool air, but the arrangement is also one which permits of a more copious supply of oil to the main bearings and connecting-rod bearings than is possible under conditions of crank case compression. Several of these engines have been put to work at sea and are giving, we learn, very good results in service.

Besides the six-cylinder unit referred to there is a two-cylinder unit with separate reverse gear, while another exhibit is a six-cylinder Crossley compressorless oil engine designed to develop 300 B.H.P. at 500 r.p.m. This engine has been specially built for electric lighting services and is suited for direct coupling to a 200-kW generator.

Blackstone and Co., Ltd.

Besides a 55 B.H.P. horizontal cold-starting "Spring Injection" engine similar to those we have described at previous exhibitions, there are to be seen on the stand taken by Blackstone and Co., Ltd., of Stamford, a range of engines of various horse-powers for land and marine transport, electricity production, and various other power duties. We have chosen for illustration in Fig. 33, page ix, a 40 B.H.P. four-cylinder marine engine which is shown on the stand fitted with a propeller and reversing gear. It has a cylinder bore of 4⅝in. and a stroke of 6in. and is fitted with the makers' new "CCC" injection system. The operation of this system can be followed from the series of drawings in Fig. 48. In A the fuel pump plunger is shown returning after the delivery stroke. It is constrained to follow the cam by a spring and draws in after it a supply of fuel oil from the inlet manifold, in which is situated a suitable filter. The inlet valve is automatically operated by the movement of the plunger through the valve lever, valve cam, and trip slide, which are clearly marked on the drawing. The valve cam, trip slide and plunger all move together, but the trip slide is additionally controlled by the governor, as will shortly be explained. In B the upward stroke of the plunger has begun and it will be observed that, the valve cam having risen, the inlet valve has been closed by the operation of the valve lever. Fuel oil is therefore now forced under pressure through the delivery valve to the sprayer and injected into the cylinder. At a certain point in the stroke, determined by the governor, the motion of the trip slide is stopped. Consequently, as shown in C, the valve cam falls into the recess cut in the side of the trip slide and allows inlet valve to open. Pressure is at once relieved, the delivery valve closes, and the remainder of the oil is returned to the manifold. It will be seen that the inlet valve, under the influence of this mechanism, always closes at the same point of the cycle in the engine cylinder, but the period of injection is variable according to the load on the engine. Besides serving for the inlet of the fuel and the spill for the excess the inlet valve serves another purpose. Should there be any stoppage in the sprayer or pipe line the valve tappet gives way and allows the fuel to escape and return to the manifold. The valve therefore acts as a relief to protect the pump from the effects of excess pressure. It is claimed for this mechanism that it ensures a sharp opening and rapid closing of the sprayer valve and eliminates the risk of "dribble." Less power, it is said, is required to operate the governor mechanism and thus closer governing of the speed is possible. Besides the "Spring Injection" engine and the vertical engines, which are shown as single, twin, three-cylinder, four-cylinder, and six-cylinder types, there is also to be seen the firm's "Fuelol" engine.

Babcock and Wilcox, Ltd.

The full-size boiler exhibits shown on the stand of Babcock and Wilcox, Ltd., of London and Renfrew, have been specially designed to draw attention to the modern trend of development in boiler practice for naval vessels, liners, and cargo steamers, and high-speed cross-Channel ships. It is worthy of note that within recent months several orders have been placed for marine boilers fitted with mechanical stokers. Many of these orders have followed, we are told, the successful installation of similar equipment on the L.M.S. steamer "Duke of Lancaster" on the

Heysham-Belfast run and the Canadian Pacific "Beaver" class cargo ships.

In America valuable experience has been gained with Bailey water walls, not only in power station boilers, but also at sea. In this connection reference may be made to the 638ft. limestone carrier "Carl D. Bradley," which is a turbo-electrically propelled steamer operating on the Great Lakes. In this ship there are installed two Babcock boilers, each having a heating surface of 5630 square feet with 1340 square feet of superheater surface and 52 square feet of Bailey bridge wall area. The boilers are designed to operate at 325 lb. pressure with 278 deg. Fah. superheat and are fired by Westinghouse retort type stokers. This ship has proved, we are informed, to be very economical in service.

In order to show a typical example of modern boiler construction embodying the various developments above referred to the firm is exhibiting—see the right-hand view above, Fig. 50—a full-size section of a standard B. and W. type marine boiler, four tube sections wide, fitted with an Erith-Roe stoker, one retort wide, with motor drive. The stoker is being shown in operation in such a way as to indicate clearly its manner of operation. The boiler, as our illustration shows, is complete with steel casings at the side, front, and rear, and the usual mountings and accessories, including soot blowers, are shown. The other boiler exhibit is the full-size section of the new small tube SX boiler, which we illustrate in Fig. 49. It is two sections wide and is similar in construction to that supplied for H.M.S. "Guardian," which boiler was recently subjected to extended tests at the firm's Renfrew works. The furnace is of the ordinary refractory construction arranged for oil firing and a B. and W. standard pressure type oil sprayer is fitted in the wall under the lower horizontal header. In the opposite wall there is a Babcock-Clyde single-nozzle blower, a section through which is reproduced in Fig. 51.

As Fig. 49 indicates, the SX model is complete with air casings, which deliver the heated air down the back of the boiler to the underside of the fire-grate. The design features of the small-tube SX boiler were fully described in THE ENGINEER of September 25th, 1931, and the arrangement of the pressure parts will be clearly seen from the accompanying engraving. In the shore trials at Renfrew on the SX boiler built for H.M.S. "Guardian," the boiler was steamed under low and high-power conditions, and showed rapid steaming with no priming. The boiler, which has no superheater or air heater, is fired by four 900 lb. Admiralty type burners. The heating surface is 5850 square feet with a total boiler weight of 40 tons. The following figures indicate the general run of the results which have been obtained on ratings commensurate with the latest merchant service practice :—

Working pressure	250 lb. per sq. in. (saturated)
Evaporation	50,000 lb. per hour
Overall net efficiency ..	85 per cent. on gross value of fuel
Outlet gas temperature ..	430 deg. Fah.
Evaporation per ton weight	1250 lb. per hour
Evaporation per sq. ft. of heating surface	8·6 lb. per hour
Evaporation per sq. ft. of floor space occupied by boiler	300 lb.

The boiler was also tested with a double furnace utilising eight 900 lb. burners, under conditions of high heat liberation corresponding to naval practice. The results obtained have been plotted in Fig. 52, giving boiler efficiency per cent. on a base of heat liberated in 1000 B.Th.U. per cubic foot of furnace volume. The accompanying curves for naval vessels are taken from Engineer-Captain S. R. Dight's paper on "Naval Water-tube Boilers," read at the spring meetings of the Institution of Naval Architects—see THE ENGINEER, April 28th, 1933—it being assumed that 19,000 B.Th.U. oil was used in all tests. The Scotch boiler curve has been added from tests made by the U.S. Naval Department at Philadelphia. A feature of the SX curve is the high efficiency which is maintained at widely varying loads and the flat nature of the curve, which, it is pointed out, would be further flattened out had a furnace with Bailey water-cooled walls been adopted. The fact that the adoption of such walls materially reduces the slope of the tangent seems to warrant the view held by the exhibitors that one of the next steps in the development of marine boilers will be the fitting of water-cooled walls. The utilisation of such walls has been steadily increasing since their introduction in 1924, nearly ten years ago, and the advantages gained on land boilers seem likely to be repeated at sea. Visitors to the stand will be able to examine for themselves the construction of such walls as applied to marine boilers and to a hopper type furnace for power station work.

We have often referred to the calorised Diamond soot blowers of the valve-in-the-head type, which are also fitted to the boilers referred to, but the Babcock-Clyde pattern, which is exhibited at Olympia for the

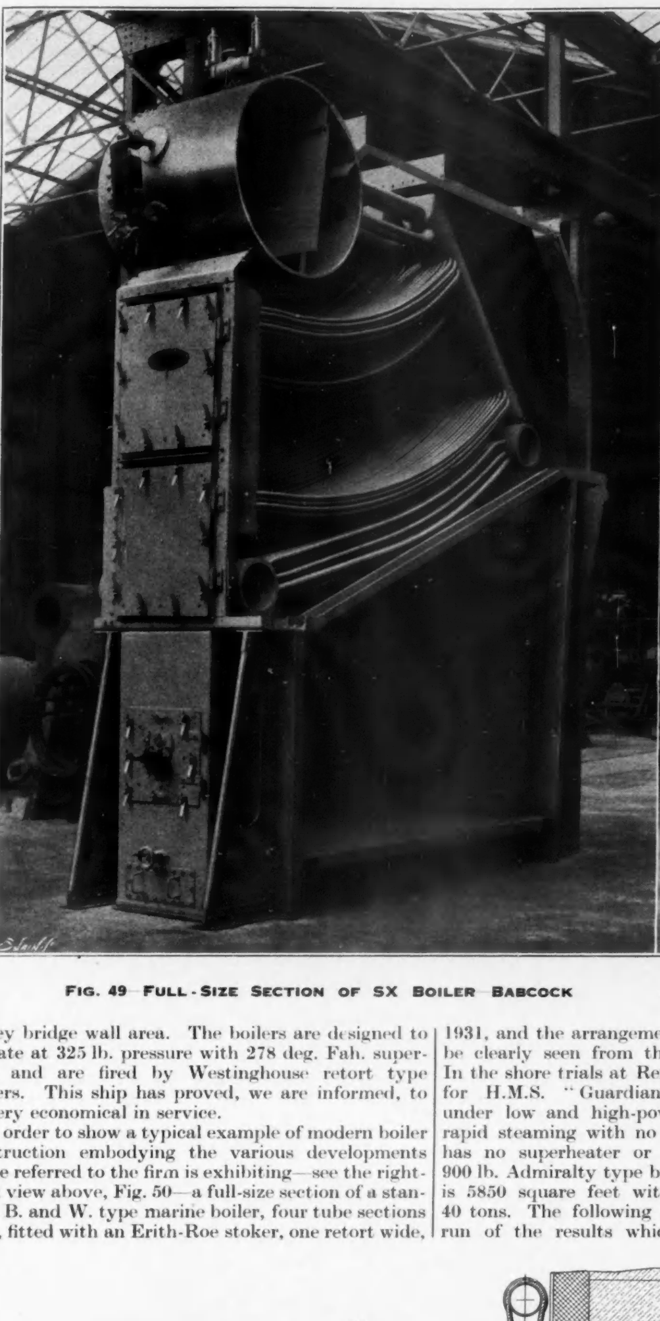

FIG. 49—FULL-SIZE SECTION OF SX BOILER—BABCOCK

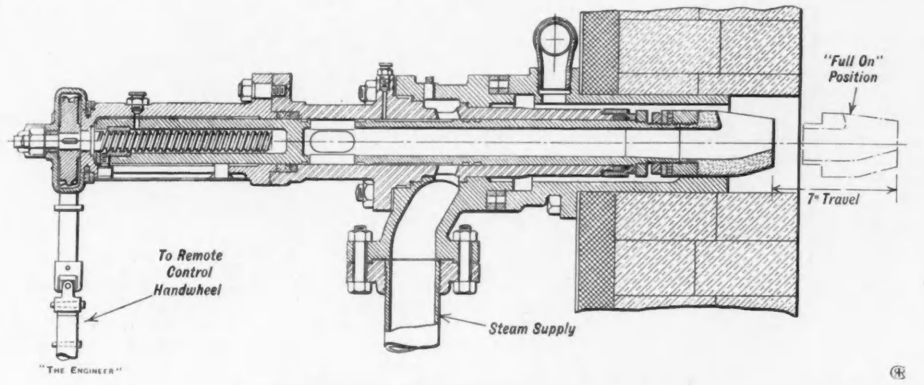

FIG. 51—SINGLE NOZZLE SOOT BLOWER—BABCOCK

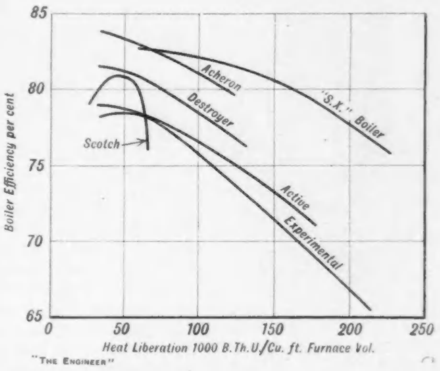

FIG. 52—RESULTS OF TESTS ON SX BOILERS—BABCOCK

first time, breaks new ground, in that by turning a wheel the steam nozzle is advanced into the furnace, steam is admitted while it is in the forward position, and the nozzle is turned through the required arc. By a reversal of the operating wheel the steam is shut off and the nozzle withdrawn. All the movements are automatic and can be read off on the indicator arranged immediately above the operating hand wheel. In the blower illustrated in Fig. 51 the operating wheel is, however, of the remote control pattern and only part of the shaft and the worm drive on the blower spindle is shown in our illustration. The working parts are protected from grit and dust and are lubricated where necessary. Air is used for cooling purposes, the air cooling inlet being on the top of the blower adjacent to the front of the boiler casing. The cover and nozzle of the blower can be withdrawn for inspection and overhaul while the boiler is under steam.

Other items on the stand relate to new developments in fusion welding and boiler specialities manufactured by the firm.

C. A. PARSONS AND CO., LTD.

In conjunction with their associated company, the Parsons Marine Steam Turbine Company, of Wallsend, C. A. Parsons and Co., Ltd., of Heaton Works, Newcastle-on-Tyne, are showing a representative collection of Parsons' products, including power station machinery, pole transformers, fabricated steel work, motor car cylinders and searchlight reflectors. A model of a 30,000-kW turbo-alternator built to a scale of one-sixteenth full size, complete with condensing plant and fuel heating system, represents the machine ordered last year by the Brighton Corporation. Designed in accordance with the firm's latest practice, the actual set runs at 3000 r.p.m. and uses steam at a pressure of 650 lb. per square inch superheated to 850 deg. Fah., which incidentally is some 50 deg. above the melting point of zinc. The steam supply is regulated by two valves working in parallel and controlled by the governor through oil relays. An independent emergency valve is, of course, also fitted to shut down the machine in the event of overspeed or loss of vacuum, whilst to ensure proper heating of the turbine while it is being started motor driven turning gear is fitted. To facilitate the work of this gear and especially to minimise the effort required to start the machine from rest, oil is admitted to the bearings at a pressure of 1000 lb. per square inch, which is sufficient to cause the shaft to float on an oil film and to eliminate static friction. The turning gear also enables the turbine to cool off uniformly and keeps it ready for instant re-starting if necessary.

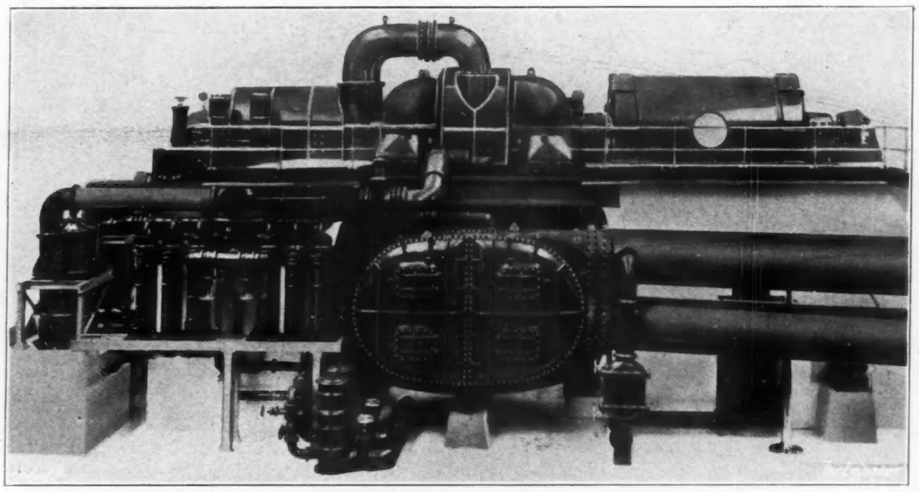

FIG. 53—MODEL OF 30,000-kW TURBO-ALTERNATOR—PARSONS

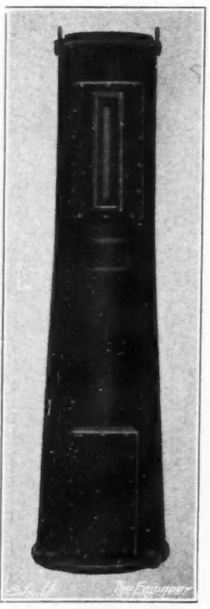

FIG. 54—WATER GAUGE PROJECTOR—PARSONS

The condensing plant is of the inverted Parsons' type with the tube nest in the centre of the shell and the steam is guided down on each side of it by baffles to the bottom of the condenser. The steam is condensed in its passage upwards among the tubes, the condensate being re-heated in falling back through the rising current of steam, so that when drawn off at the bottom of the condenser it is at full exhaust steam temperature. The air is withdrawn at the top of the shell, where it is coolest, and completely free from entrained moisture by a three-stage steam-operated ejector. As there are no baffles of any kind among the tubes, the steam and air flow is not obstructed and the entire surface of every tube can do its proper share of work. The design is claimed to result in an exceptionally high rate of heat transmission, a minimum pressure drop across the condenser, and the highest possible temperature of the condensate. The inverted condenser offers the further advantage that it serves both exhaust branches of the turbine and the need for twin condensers for a double exhaust machine does not exist. After the condensate has been withdrawn from the condenser by a motor-driven centrifugal pump it is progressively heated to a temperature of 340 deg. Fah. by steam extracted from the turbine at four points.

The continuous maximum rating of the totally enclosed alternator is 37,500 kVA at 8000 volts, and it is ventilated on the totally enclosed system, in which the same air is kept in continuous circulation and cooled after passing through the machine by an air cooler included in the circuit. Two motor-driven fans are provided, each of sufficient capacity to enable the machine to develop three-quarters of its rated capacity continuously. A view of the model as shown at the Exhibition is given in Fig. 53.

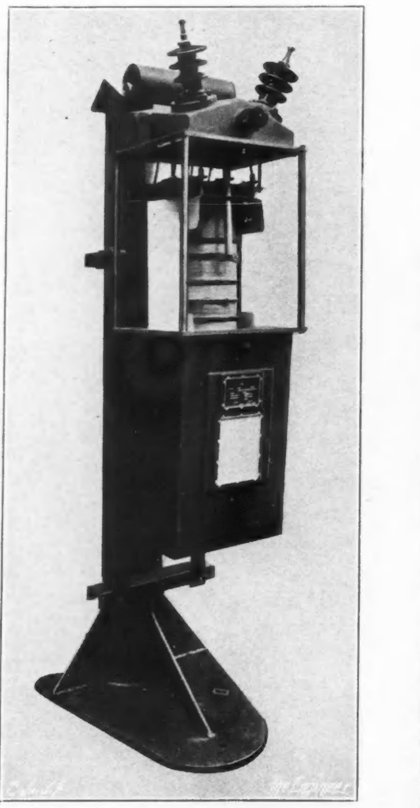

FIG. 55—25-kVA POLE MOUNTING TRANSFORMER—PARSONS

An air cooler for use in conjunction with a turbo-alternator in the manner described and capable of dealing with 36,000 cubic feet of air per minute constitutes another exhibit. To facilitate assembly and withdrawal through the sides of the foundation block it is mounted on rollers. It consists of a nest of tubes terminating in tube plates to which cast iron water boxes are attached, the tubes being held in the unit so as to permit of free expansion and contraction, and any tube may be withdrawn or replaced without disturbing the remainder. Although the tubes in the cooler shown are composed of brass, copper tubes are sometimes used, and each is wound from end to end with a corrugated fin in the form of a continuous spiral, the fins being soldered to the tubes to ensure good thermal conductivity.

The Parsons water gauge projector shown in Fig. 54 has been designed for use in boiler-houses. With its aid an attendant on the firing floor is provided with a brilliantly illuminated image of the gauge glass on the boiler drum, which may be 50ft. or 60ft. above his head. The result is obtained without interference with the actual gauge glass, the image being thrown by optical means on to a ground glass screen mounted on the pedestal on the firing floor and is visible from a considerable distance and through a wide angle. The instrument is shown working in conjunction with a Dewrance water level indicator suitable for pressures up to 700 lb. per square inch, erected together with the necessary projecting apparatus on the gallery over C. A. Parsons' stand, on which the image of the gauge glass can be seen on the screen in the pedestal.

A 25-kVA single-phase pole mounting transformer as shown in Fig. 55 is also to be seen. It has been designed for rural electrification schemes, the ratio being in this particular case 11,000/400 volts. Transformers of this kind are made, however, for primary pressures up to 33,000 volts and for outputs ranging from 10 to 50 kVA. Other electrical exhibits are specimens of the Parsons' patented concentric stator conductors as used in the Parsons' 36,000-volt alternators, and an exciter for a turbo-alternator. Details of the end winding connections for these high-voltage machines are shown in Fig. 56. The exciter is a 35-kW overhung four-pole 150-volt 3000-r.p.m. machine with the armature mounted directly on the main rotor shaft.

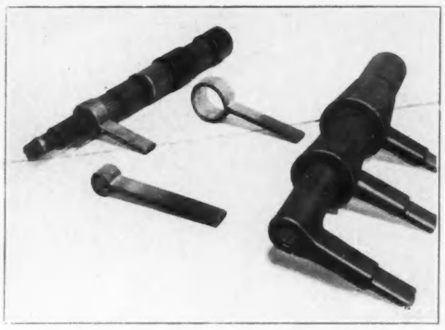

FIG. 56—END WINDING CONNECTIONS—PARSONS

Other exhibits consist of the Parsons borescope, as used at the Heaton works for the detailed examination of the interior of rotor forgings, pipes, &c.; a fabricated steel pipe and expansion piece; motor omnibus cylinders; a gun-metal tail shaft liner for a ship's shaft; silvered glass reflectors for searchlights; and other apparatus and samples of turbine blading. The ductility of the firm's stainless iron blading is illustrated by a piece of blade strip which has been twisted through five complete revolutions without showing any sign of fracture. Another interesting sample is a blade for the exhaust end of a turbine and fitted with the Parsons' patented shield to prevent corrosion. This form of protection is now employed on all Parsons' machines for blades subjected to the erosive action of wet steam and is said to give an indefinitely long life to the blades under the most adverse conditions. The shields consist of intensely hard metal and are fixed by brazing to the leading edge of the blades, and if it should ever be necessary to renew them the job can be done without removing the blades from the rotor.

EDWARD BENNIS AND CO., LTD.

The two main developments in stoker design made by Edward Bennis and Co., Ltd., of 28, Victoria-street, London, S.W.1, since the last exhibition at Olympia have been a modification of the method of supplying air for combustion to the furnaces of a boiler, and the introduction of cold air internally through the grate bars in order to prevent overheating of the metal when using preheated air for combustion. The furnace grates of the new design, which is exemplified on the stand as applied to a three-flue marine Scotch boiler, are composed of a number of hollow trough bars. While the self-cleaning action of the older type is retained, the furnace troughs of the new unit are adapted to suit the supply of air for combustion at a lower pressure and velocity than would be the case with a furnace served by steam jets. It is claimed that the new system overcomes the tendency of the bars to swell under the conditions of high temperature caused by burning fuel in preheated air. Cold air currents forced under pressure through each of the bars from front to rear keep the bars at a comparatively low temperature, while air for combustion is introduced under pressure into the front tubular end of each trough by separate nozzles. These air nozzles are arranged upon a common duct fixed immediately in front of the grate in such a way that their centres correspond with those of the fire-bar troughs. The air pressure is maintained by a fan.

THE BRITISH OXYGEN COMPANY, LTD.

Manufacturers of articles such as tanks which are made up from steel plate have hitherto found it necessary to make two cuts for preparing the bevels on the meeting edges of the plate. The edges, of course, are usually bevelled before the plate is bent into shape. If plates are purchased from the steel makers to a definite size sufficient for making up the article with no waste, the ends must each be bevelled as a separate operation. If, however, the steel plate is purchased in sufficient size to permit of two or more plates being cut from it, the separation may be made by two cuts, each of which prepares the bevelled edge ready for welding. This arrangement is made possible by the new device introduced by the British Oxygen Company, Ltd., of Edmonton, London, which consists of a two-nozzle head suitable for attachment to any of the firm's ordinary machine cutting blow-pipes. Three different angles of cut are available by means of different heads, and heads will, we understand, shortly be available for cutting angled bevels of 60 deg., 75 deg., and 90 deg. on any thickness of plate from ¼in. to 1in. The device is illustrated in Fig. 57.

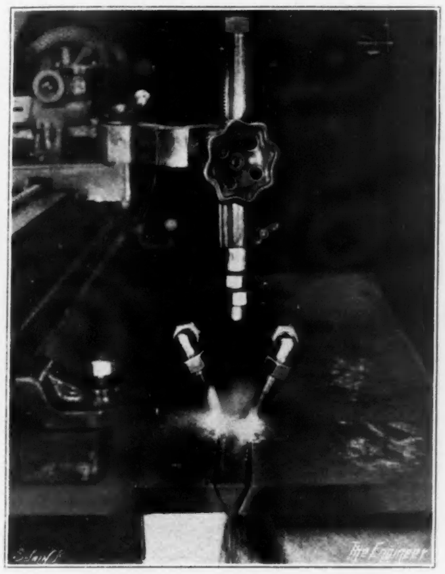

FIG. 57—DOUBLE BEVEL CUTTING ATTACHMENT—BRITISH OXYGEN

The edges left by the cut are, it is claimed, perfectly smooth and no further preparation for welding is necessary beyond a brushing to remove the loose scale which usually adheres to portions of the cut. Needless to say, this device is only for attachment to cutters working on straight-line cutting machines and is not suitable for use on profile cutting machines. Some doubt sometimes exists concerning the desirability of preparing welding bevels by gas cutting, and for several years it has been the practice in many industries to prepare welding bevels by hand operated flame cutter. If hand cutting is already employed, it is reasonable to assume that machine cutting can also be employed with a greater degree of certainty and uniformity of results. With these facts in mind, the firm recently undertook a series of comparative tests on bevels prepared in the following manners:—Saw cut; hand oxy-acetylene cut; machine oxy-acetylene cut; machine oxy-coal gas cut. The average results obtained are given below:—

	Yield point. Tons per sq. in.	Breaking load. Tons per sq. in.
Saw cut	18·25	25·35
Hand oxy-acetylene ..	18·0	25·85
Machine oxy-acetylene ..	18·6	23·95
Machine oxy-coal gas ..	18·4	23·8

It will be noticed that the results do not indicate any appreciable difference between the various methods of preparation. The welds were made using the oxy-acetylene hand process, the same welding rods being employed throughout; after welding, the weld surface was machined down flush with the surface of the plate. The welds themselves were very consistent and for each condition of bevel preparation four welds were made. The use of these special cutting heads provides many possibilities of application; apart from use on steel plates they have already been applied to the cutting of tubes used for heating and supply installations. The cutter with the heads is mounted in a special machine which traverses the cutter circumferentially round the tube.

Besides this double cutter head the firm is showing its usual large range of cutting machines of various types, together with specimens of parts cut. Demonstrations are continually being made, both on the machines and with the hand welding and cutting machines made by the firm. Among the most recent productions to be seen on the stand are new blow-pipes for glass working; blow-pipes for removing defects from semi-finished steel and also for machining slabs and bars of steel to reduce sizes; jet welding blow-pipes for increasing the speed of hand oxy-acetylene welding; and a new welding rod for depositing metal on worn or battered rails. In connection with the last-mentioned it is claimed that while the characteristic brittleness of electric welds is avoided the metal deposited is elastic and accommodates itself to the underlying rail metal to which it adheres. Provided the correct procedure is observed during the making of the deposit, the deposited metal will not flake or split away from the rail metal. The rate of deposit and its shape can be easily controlled by the operator. Furthermore, the deposit may even be hammered to obtain a smooth running surface, so eliminating the necessity for grinding. The makers give a figure of about 300 Brinell as the hardness of the deposit and claim that the rail metal adjacent to the weld is not softened.

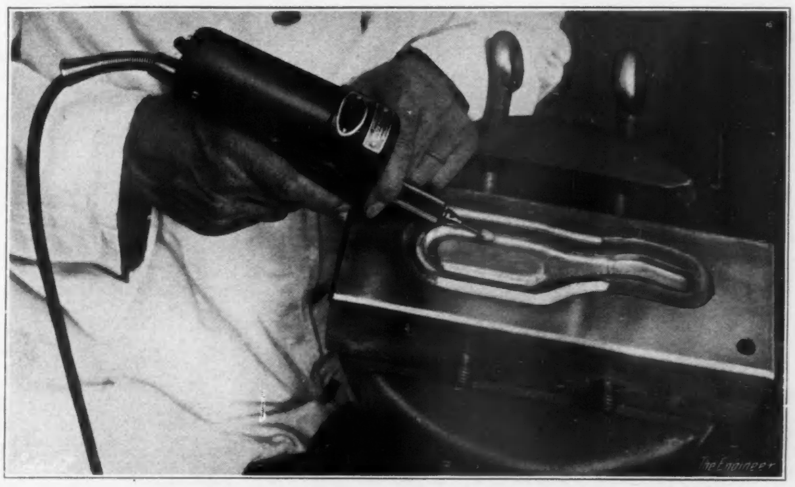

FIG. 58—ELECTRIC GRINDER FOR MOULDS AND DIES—BOSCH

BOSCH, LTD.

The principal exhibit of Bosch, Ltd., of Larden-road, Acton, W.3, consists of mechanical force feed oil and grease lubricators for the lubrication of steam and oil engines, air compressors, machine tools, colliery and brick-making plant, rolling mills, &c., and a variety of electric tools. The 50,000 r.p.m. grinder shown in Fig. 58 is suitable for re-machining press and stamp tools which have been distorted during the hardening process, for cutting from the solid irregular shaped articles, for smoothing off burrs and for polishing. The tool is driven by a universal series-wound motor, suitable for A.C. or D.C., and may be supplied for pressures of 110, 125, 150, 220, or 240 volts. At normal load the consumption is 50 watts. A built-in fan serves for cooling the machine, which transmits its power to the grinding spindle from a pulley serving as a fly-wheel, and giving a speed ratio of 1 : 4, the speed of the rotor being 12,500 r.p.m. The high spindle speed which produces the required circumferential velocity, even with very small grinding wheels, the smooth running and the good pull, combine to make the grinder suitable for performing the most accurate and delicate work. The grinder may be used for machining materials such as hardened and non-hardened steel, grey iron, bronze, brass, silver, glass crystals, and semi-precious stones. For machining glass crystal, ceramic products, &c., the machine is equipped for wet grinding, whilst for polishing, suitable polishing attachments are supplied.

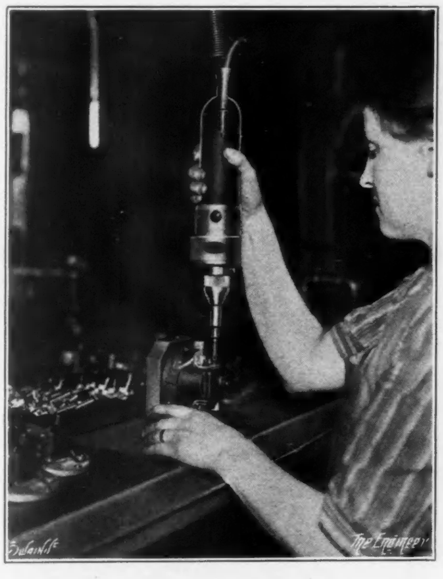

FIG. 59—ELECTRIC SCREWDRIVER—BOSCH

The electric screwdriver, shown in Fig. 59, is suitable for use in all industries in which screws of a similar nature have to be screwed tightly into metal or wood. It is light and easy to manipulate, and a slipping clutch ensures that the drive blade comes to rest immediately the screw has been driven home and when the driver has been removed from the slot. Special centring sleeves for picking up and holding any type of screw are supplied. The motor is a universal machine suitable for A.C. or D.C.

The hand motor shown in Fig. 60 may be used for numerous purposes, such as finishing off dies and moulds, machining patterns, fettling castings and welds, removing burrs, cutting oil grooves, drilling holes in steel, &c., up to ¼in. diameter and in stone, glass, ceramics and wood up to $\frac{5}{16}$in. diameter, reaming small holes, roughing rubber, and decarbonising engines by means of rotary wire brushes. The motor is a universal machine suitable for A.C. or D.C., and is supplied for pressures of 110, 150, and 220 volts, the consumption under load being 50–60 watts. The armature speed is about 20,000 r.p.m., which is reduced to 1500–1600 r.p.m. by means of reduction gearing.

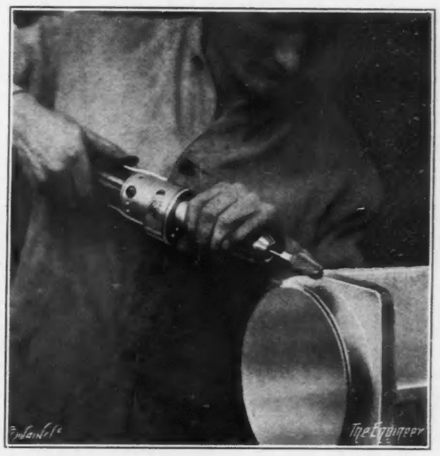

FIG. 60—ELECTRIC HAND MOTOR—BOSCH

JOHN I. THORNYCROFT AND CO., LTD.

On the stand of John I. Thornycroft and Co., Ltd., of London, Southampton, Basingstoke, and Reading, prominence is given to the firm's new compression-ignition engines of the high-speed, heavy-oil type, which are rapidly finding increasing uses for marine and land transport work. Some of the engines shown have been exhibited at previous Exhibitions, but a new addition to the series is the R M 4 engine, now on view for the first time.

In Fig. 61 we reproduce sections through the engine, and on page viii, Fig. 28, we illustrate a similar unit of the six-cylinder type which has a designed output of 50 to 65 B.H.P. at 1200 to 1600 r.p.m.

The new four-cylinder compression-ignition engine has a bore of 4in. and a stroke of 6in., with a rated output of 36 B.H.P. at 1200 r.p.m., with a brake mean effective pressure of 78 lb. per square inch.

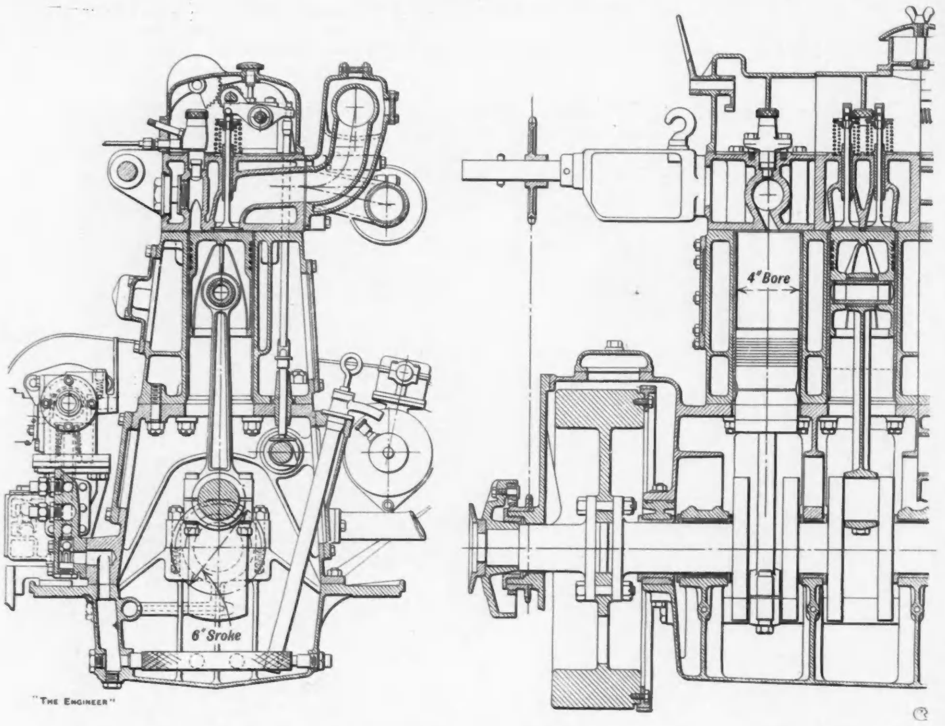

Fig. 61—Sections through 36 B.H.P. Four-Cylinder Oil Engine—Thornycroft

It can be started by hand by means of the usual overhead shaft and chain drive, or, if required, an electric starter can be supplied.

The fuel consumption per hour is approximately 2 gallons, or 9 litres, and the lubricating oil consumption per hour is approximately 0·6 pint, or 0·34 litre. The engine, generally, has been designed to meet the requirements of the British Admiralty for an engine of this type, and complies with the requirements of Lloyds and the Board of Trade as to size and materials of component parts. It can be built under survey if required.

As the drawing Fig. 61 shows, the crank shaft is carried in the bottom half of the crank case in main bearings of large diameter, supported by ribs. The top half of the crank case, which serves to transmit the stresses from the crank case to the cylinder block, is a stiff casting, strongly ribbed and provided with large doors, through which pistons, connecting-rods, and all main bearings may be removed without dismantling. The clutch and reversing gear are integral with the engine, in so far that they are contained in a separate casing bolted rigidly to facings on the main crank case. In the event of a reversing gear not being required, this casing may be replaced by an end cover, which renders the engine suitable for dynamo driving or other stationary purposes.

The main cylinder block is cast in chromium iron and is furnished with large doors, through which the jackets may be easily cleaned. It is fitted with cylinder liners of Nitralloy cast iron, honed in place after fitting.

The pistons are of an aluminium light alloy, and carry four main rings and one oil-control ring, while the gudgeon pins are a floating fit in the piston and are prevented from coming into contact with the cylinder walls by brass pad pieces at either end. Special interest attaches to the use of a flat-topped piston and an auxiliary chamber with an oblique passage connecting it to the combustion space. The arrangements are clearly shown in drawing Fig. 61.

The cam shaft is mounted in the top half casing and actuates the valves by means of rockers and push-rods. Provision is made for the lubrication of all the valve gear by pressure from the main oil pump, which is of the plunger type and runs at half-engine speed. All the auxiliaries, such as fuel pump, oil pump, bilge pump, and tachometer drive, are mounted on the engine in such a way as to be immediately accessible for examination and repair without any dismantling work having to be done. Both the governor and the control gear are incorporated in the fuel pump, which is at present of Bosch manufacture, though any other make of pump, interchangeable as regards dimensions, can be fitted.

The weight of the engine with the crank case of cast iron, as illustrated in Fig. 61, is approximately 19½ cwt., or 990 kilos., but where lightness is specially required the crank case can be manufactured in aluminium alloy, the corresponding weight being approximately 16 cwt., or 787 kilos. The above weights do not include, however, the electric starter, which, including the battery, makes an addition of approximately 1½ cwt., or 76 kilos.

In addition to the compression-ignition engines above referred to, a representative range of Thornycroft paraffin marine engines, from 9 up to 55 B.H.P., fitted with reversing or reversing and reduction gears, is displayed. There are also shown examples of Thornycroft oil-fuel-burning equipment, and ships' propellers, whilst models of naval vessels, merchant ships, and yachts built by the firm illustrate the varied products dealt with at the firm's different establishments.

Foundry Equipment, Ltd.

On the stand taken by Foundry Equipment, Ltd., of Westminster, are to be seen chain blocks and combined chain blocks and trolleys, suitable for a wide range of loads. The "Felco" triple gear chain blocks have been recently introduced by the firm, and are here exhibited for the first time. These blocks are made in a range of sizes from ½ to 10 tons, and the drawing reproduced in Fig. 62 shows the 1-ton size.

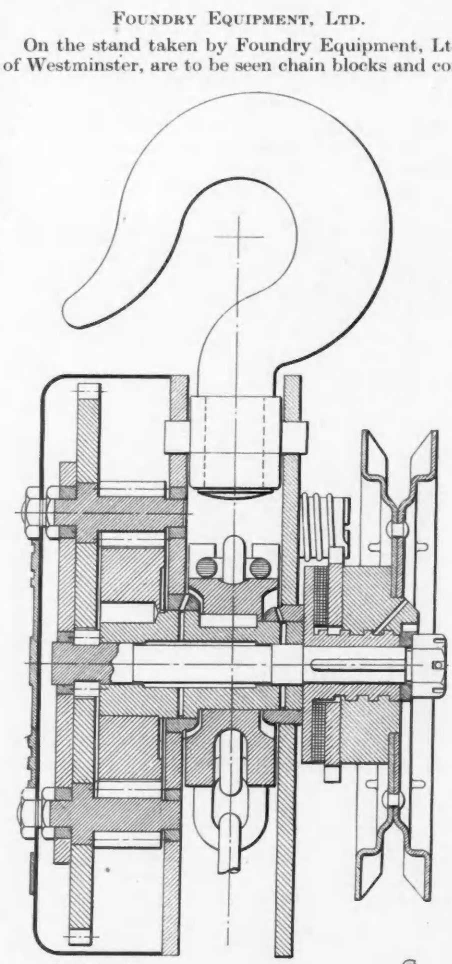

Fig. 62—1 Ton Chain Block—Foundry Equipment

The main frame is made of solid steel plates, and is so constructed that the makers claim it to be unbreakable and not liable to distortion. The hand wheel, which is a heavy gauge steel stamping instead of the casting sometimes employed by makers of these devices, is keyed on to the end of the pinion shaft. This shaft extends right across the mechanism, and carries at its further end a pinion engaging with two intermediary hardened, machine-cut gears. Pinions cut solid with the larger wheels engage with the central load wheel gear, which is keyed to a shaft encircling the pinion shaft. In the centre and keyed to the load wheel shaft is the load wheel itself. Braking is effected by a screw plate, ratchet, and pawl, all of hardened steel and special fibre friction washers. This device is mounted just beside the hand wheel. Lubrication of the gears by an ample supply of thick grease contained in the steel casing enclosing them has been adopted, while the various bearings have radial oil grooves cut in steel plates. The makers inform us that all these blocks supplied are tested to 50 per cent. overload working and 100 per cent. overload static. A photograph reproduced in Fig. 63 gives some idea of the appearance of a block of larger size—8 ton.

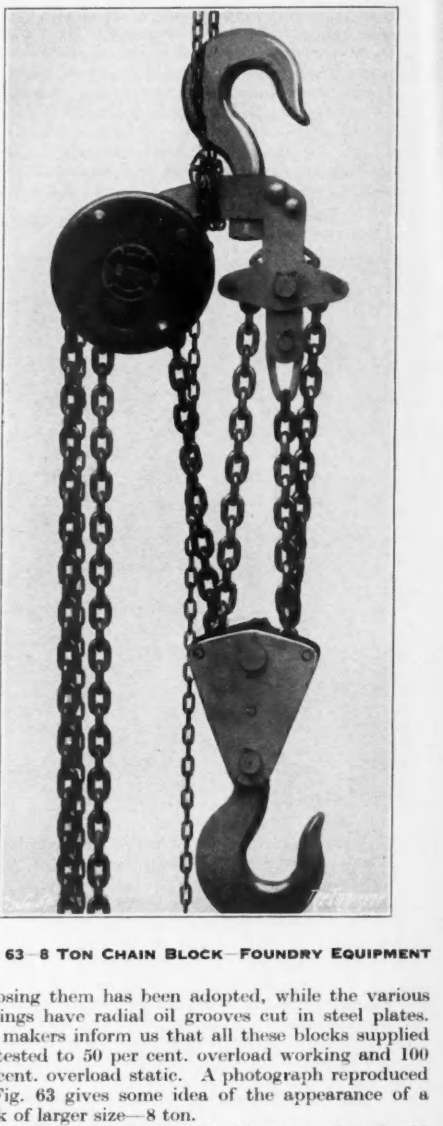

Fig. 63—8 Ton Chain Block—Foundry Equipment

In addition to these chain blocks, notice should be taken of the combined chain blocks and trolleys. By building the block into the trolley, the makers have reduced considerably the headroom from the underside of the joist to the inside of the bottom hook when in the highest position. In the half-ton size, for instance, this dimension is only 11½in. and in the 2-ton size 17½in.

Thomas and Bishop, Ltd.

The firm of Thomas and Bishop, Ltd., besides showing the "Flexo" belt dressing which it has been manufacturing for over thirty years and the "Flexo" tinning compound, for which it is claimed that two pieces soldered together by its means cannot be torn apart without risk of fracturing the metal, is also showing an entirely new range of products known as "Kester" solders. This series of self-fluxing wire solders is made of virgin tin and lead. Each wire contains within it, like the lead within a pencil, the flux suitable to the purpose for which the solder is to be used and in a proportion which has been found experimentally to give the best results. The three chief types of Kester solder are "acid core," which is of the general utility variety and is to be preferred for outdoor work; "rosin core," suitable for wireless and telephone work, which leaves only a transparent residue and prevents corrosion and electrical leakage while being harmless to metal parts; and "body solder," which is specially designed for the repair of damaged motor car mudguards and bodies.

A Seven-Day Journal

The Proposed Gibraltar Tunnel.

PRELIMINARY surveys for the proposed tunnel under the Strait of Gibraltar, show that the geological conditions are favourable to the successful carrying out of the scheme. When the surveys are completed, towards the end of next year, it is hoped to constitute an international company with British, French, and Spanish capital, but the work of constructing the tunnel will not be started until there is some assurance that the African railway projects will be put in hand at the same time. One of these is a railway along the west coast through French Morocco and the Rio del Oro to Dakar for the traffic with South America; another is the Transafrican railway across the Sahara Desert, which will be connected up with the Belgian Congo railway system, and eventually with the railway to the Cape; and, finally, there is a scheme for extending the railways across North Africa to Egypt. The lesson of the tunnel through the eastern Pyrenees, which has failed to fulfil the promise of promoting commercial activity made at its inauguration some years ago, is not lost upon the promoters of the Gibraltar tunnel, who intend to make sure that railway enterprise in Africa will justify its construction. The Spanish decree of December, 1931, which modified the character of the Commission of Inquiry formed in 1928, declared that the object of the tunnel was to make the Spanish railway system a link in a chain of communications with Europe, Africa and America. It is proposed to construct the tunnel from a point 5 miles west of Tarifa in Spain to Cale Hermosa in Spanish Morocco, a distance of about 20 miles. There will be two tunnels, with lateral tunnels every 200 m., and the maximum depth below water level will be 370 m. The maximum gradients will be 3·6 per cent. The strategical value of the tunnel will raise political problems which will have to be settled before the undertaking can be put in hand.

The Ryburn Reservoir.

ON Thursday afternoon, September 7th, the new Ryburn reservoir, near Sowerby Bridge, was formally opened by Councillor Charles Hopkinson, the Chairman of the Wakefield Corporation Waterworks Committee. The curved concrete dam which has been constructed across the valley has a height of 100ft. and a width of 600ft., the curve being on a radius of the same dimension. The capacity of the lake thus formed is 220 million gallons. The downstream face of the dam is stepped, and narrows downwards to 87ft. at the base. Over it 1,300,000 gallons per day of compensation water are allowed to flow. The whole of the work has been carried out to the designs and under the supervision of Mr. C. C. Smith, the Corporation waterworks engineer. Nearly all the concrete required was poured under gravity, and a feature of the construction was the use of bore-holes filled with cement under pressure, which extend over the parts below and adjacent to the sides of the dam. The total cost of the Ryburn dam is about £245,000, making a total of between £500,000 and £600,000 spent on the scheme so far completed, which includes a 23-mile pipe line to Wakefield with the tunnels and bridges required. A further reservoir, which is to be placed higher up the valley, will complete the scheme for the construction of two reservoirs at a cost of about £960,000, which was sanctioned under parliamentary powers in 1924.

Olympia.

ON Thursday, September 7th, the Shipping, Machinery and Engineering Exhibition was opened by the Earl of Athlone. He spoke optimistically of the general outlook in trade and industry, and gave examples to illustrate the improvement that was taking place. In shipbuilding, for instance, last month had been the best in the year on the Clyde, orders for five ships having been placed and five ships having been launched. Although the total output for the month was only a little over 9000 tons, there was a prospect that the total for the year would show an improvement on that for last year. Similar figures were true for other shipbuilding centres. That revival, coupled with the possibility of new naval orders, justified the expectation that better times were coming for engineering in all its branches. At the luncheon which followed, Lord Stonehaven, presiding, expressed the opinion that the Exhibition was a testimony to the technical skill, ingenuity, courage, and perseverance of those engaged in the shipping, engineering and machinery industries. In the evening a dinner was held in honour of and to welcome overseas visitors. It was a cheerful function, and the remarks of the various visitors who spoke gave proof of the bonds that hold the widely separated countries of the Empire together. After the toast of "International Shipping and Engineering" had been proposed by Mr. W. A. Tookey and acknowledged by Mr. J. Foster Petree, Mr. D. A. Bremner, in a speech with just that touch of humour so necessary after dinner, proposed the toast of "Our Overseas Guests." Mr. B. H. J. Tubb, of Rhodesia, and Councillor E. H. Van Whitt, of South Africa, responded. Sir Thomas Wilford, High Commissioner for New Zealand, proposed the toast of "The Chairman," and the response by Lord Stonehaven brought the day's proceedings to a close.

The Proposed Water Grid.

DURING the past week opinions divergent in character, some of them with inspired knowledge, no doubt, have been expressed on the proposed water grid, a recent subject of much non-technical writing. Speaking at the opening of the Ryburn reservoir of the Wakefield Corporation waterworks last week, Mr. Arthur Greenwood, Minister of Health in the last Labour Government, said that the problem of water supply had got beyond the scope of the single authority. We were now, he said, being led in the direction of looking at water supply from a much wider view, and he expressed the hope that in six years something like a national plan for conserving and distributing water would be adopted. In a conference of Lancashire Urban District Councils, which took place at Fleetwood on Saturday, September 9th, Professor Abercrombie, of Liverpool, expressed a similar hope, and pointed out the need of regional planning, and the saving in expense thereby attainable. Mr. G. M. Robertson, of Fleetwood, the Chairman of the British Waterworks Association, referred at the same conference to the supply problem, but pointed out that the conditions of electricity and water supply were entirely different. In water there was the question of gravitation, the source of supply, and the method of distribution. Recently the Government had been seeking information from the water authorities as to the supplies of water available, what reserves they had, and the extent of the gathering grounds, but he was personally of the opinion that it would be a long time before there was a water "grid" in this country.

Electricity Supply.

THE official returns rendered to the Electricity Commissioners show that 928 million units of electricity were generated by authorised undertakers in Great Britain during last month, as compared with the revised figure of 816 million units in the corresponding month of 1932, representing an increase of 112 million units or 13·7 per cent. The number of working days in the month, excluding Sundays and Bank Holiday, was the same as last year, namely, twenty-six. During the first eight months of 1933, up to the end of August, the total amount of electricity generated by authorised undertakers was 8329 million units, as compared with the revised figure of 7718 million units for the corresponding period of 1932, representing an increase of 611 million units or 7·9 per cent. Following the conclusion of an agreement last July for two power stations of J. and P. Coats, cotton and thread manufacturers, to be brought into the Central Electricity Board scheme, the Board had entered upon negotiations with other industrial concerns, owning their own generating stations. The number of stations in industry, coal mines, commerce, &c., is in excess of 4000, and although it is not anticipated that all people generating their own current will take advantage of the "Grid," it is expected that many of them will do so.

A B.A. Luncheon Party.

MR. R. W. ALLEN, the President of Section G of the British Association, gave, on September 12th, a private luncheon at the Grand Hotel, Leicester, at which were present the President of the Association (Sir Frederick Gowland Hopkins, Pres. R.S.), Sir Josiah Stamp (Treasurer, British Association); the two General Secretaries (Professor F. J. M. Stratton and Professor P. G. H. Boswell), Sir Henry Fowler, K.B.E., the members of the Committee of Section G, together with the Recorder, the Secretaries, and the Local Hon. Secretary, and a number of other guests. The proceedings were entirely informal, but Sir Henry Fowler could not resist the opportunity of making a short speech, in which he spoke in a quite intimate manner to and about the President, recalling with pride the work done by Mr. Allen's father in the cause of engineering progress and education. Mr. Allen replied in a similar strain, ruling Sir Henry absolutely out of order. Expressing his personal pride at having been selected as President of Section G this year, Mr. Allen commented on the enormous ramifications of the work of the various Sections of the British Association and of the difficulty of covering all the ground which was made available, especially in the way of visits. For that reason he feared that some of the works which were open for inspection did not receive such large parties as might have been anticipated. In the same way he commented on the difficulty of giving adequate time to the discussion of the papers presented to Section G. (There are those who incline to the view that Section G may itself have to be sectionalised before long in order to be able to deal with all the papers that are available.) Mr. Allen concluded by mentioning that although there were responsibilities for the President of Section G, they were considerably lightened by the work of the Recorder, Mr. J. S. Wilson, and the two Secretaries (Dr. S. J. Davies and Mr. J. E. Montgomrey)—a tribute in which we ourselves would like to join in respect of the manner in which the Press is catered for in Section G.

A Coke Problem.

IN the course of the William Young Memorial Lecture, which was delivered in Paisley on Thursday, September 7th, by Dr. F. S. Sinnatt, Director of Fuel Research, London, before the annual meeting of the North British Association of Gas Managers, the lecturer put forward a strong plea for the continuance of a united attack by the British gas industry on the coke problem. Dr. Sinnatt said that the problem of domestic heating would only be solved when an "all-purposes" coke, which would be suitable for every domestic requirement, was manufactured. Large-scale experiments were being carried out by a number of gas companies and coke manufacturers, both upon the blending and the production of special cokes. Smokeless fuel made by the carbonisation of coal at lower temperatures was, of course, suitable for ordinary household purposes. The title of Dr. Sinnatt's lecture was appropriately "Young, Beilby, and Some Experiments on the Carbonisation of Coal." In it he paid a warm tribute to the pioneer work of William Young; to Sir George Beilby, the first Director of Fuel Research, and to the late Professor Thomas Gray, of the Royal Technical College, Glasgow, who was Superintendent of the Fuel Research Station.

The Scottish Oil Industry.

SOME interesting figures with regard to the oil supplies of Great Britain are contained in the report of the Petroleum Department, which is included in the twenty-fifth annual report of the Chief Inspector of Mines, for 1932, just issued by the Stationery Office. The report states that although this country ranks as the third largest user of petroleum products, next to the United States and Russia, both large oil-producing countries, there are, apart from the oil shale field in Scotland, practically no proved natural oil supplies in Great Britain. According to the report, the Scottish shale oil industry has been seriously contracting. Oil shale is mined in Mid and West Lothian, and the output in 1932 was 1,369,000 tons, valued at £363,000, as compared with 1,733,000 tons, valued at £482,000, in 1931. The amount of crude oil treated at the refinery was 29,679,000 gallons in 1932, compared with 36,524,000 gallons in 1931. The decrease in output, it is explained, was due to the fact that in the autumn of 1931 it had been found necessary, owing to the low level of prices which petroleum products had reached, to effect a contraction in the size of the industry by the elimination of the less efficient crude oil works, shale mines, and one refinery. By the use of the most up-to-date methods, and the cracking of the heavy oil to produce larger quantities of motor spirit, the industry has, however, been maintained in existence. Reference is also made to the scheme for rationing work recently introduced. The scheme has met with an excellent reception throughout the shale oil district, and information in the possession of the Department shows that a loyal effort has been made by all concerned to ensure its success.

High Wycombe Waterworks.

ON Saturday last, September 9th, Lord Cottesloe, the Lord Lieutenant of the County of Buckingham, opened the new waterworks extensions at High Wycombe, which have been designed to supply a wide area in the southern part of the county. The new scheme, now completed, includes a bore-hole and pump-house at Pann Mill, with reservoirs at Bowerdean and Widdenton Park Wood, and interconnecting steel mains. The bore-hole has a diameter of 42in. and a depth of 268ft. It is lined to a depth of 90ft., and at the top there is a well 7ft. diameter, extending to a depth of 34ft. A yield of 150,000 gallons per hour has been obtained at a depth of 48ft. from the surface. The pumping plant comprises a two-stage bore-hole pump at a depth of 80ft., which lifts the water to the suction of the two surface pumps. One of these is a six-stage centrifugal pump designed to deliver 50,000 gallons per hour to the Widdenton Park Wood reservoir, and the other a three-stage centrifugal pump with a capacity of 100,000 gallons per hour, which serves the new low-level reservoir at Bowerdean. The interconnecting mains are 15in. diameter and are of solid drawn steel. The pumping plant was supplied by the Worthington-Simpson Company, Ltd., of London and Newark, and is electrically driven, current being taken from the local supply undertaking at 6000 volts and transformed down to 400 volts at the motors. The two reservoirs are constructed in reinforced concrete on the Hennebique system, and are each divided into two compartments. The Bowerdean reservoir has a 2,000,000-gallon storage capacity, while that at Widdenton Park Wood has half that capacity. The consulting engineer for the scheme is Mr. W. Vaux Graham, M. Inst. C.E., M.I. Mech. E., of Westminster, who collaborated with the waterworks engineer and manager, Mr. S. Young. The cost of the new works referred to above is approximately £78,000.

The Shipping, Engineering and Machinery Exhibition at Olympia.

No. II.

(Continued from page 230, September 8th.)

THOMAS MERCER.

SINCE the last Shipping, Engineering and Machinery Exhibition at Olympia, Thomas Mercer, of Eywood-road, St. Albans, engaged for many years in the manufacture of accurate time measuring instruments, has introduced a wide range of measuring gauges, many of which are exhibited at the present show. For the measurement of barrels or cylinders, gauges from ⅞in. to 36in. capacity are displayed. The former are used for measurements on tubes, &c., whilst the latter are suitable for use on oil engine cylinders and other objects with relatively large bores. There are also dial micrometers for use in printing, rubber, sheet metal, and general works. Depth gauges of the diaphragm type, for use in ship and other tanks, up to 9ft. deep, and time measuring instruments for use on ships constitute other exhibits.

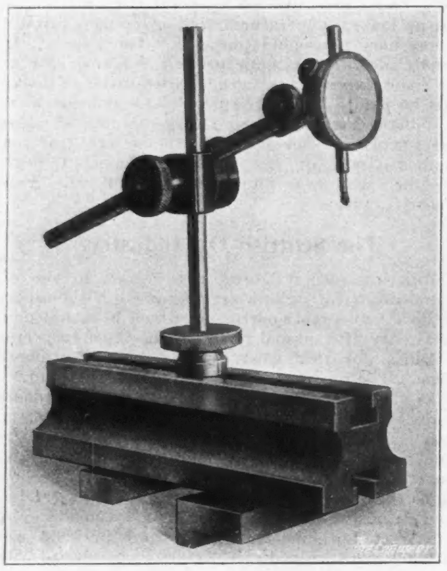

FIG. 28—DIAL TEST INDICATOR—MERCER

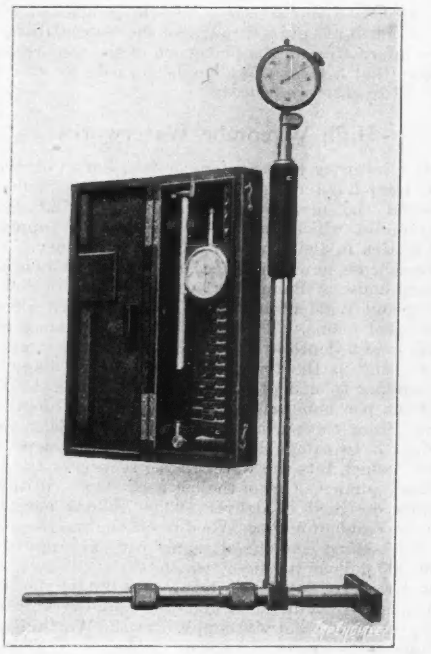

FIG. 29—CYLINDER GAUGE—MERCER

The dial test indicator illustrated in Fig. 28 is for showing the lack of roundness or the excentricity of rotating shafts, &c., for aligning parts of machines, proving parallelism of surfaces, and for many other jobs carried out by fitters and inspectors in engineering workshops.

The cylinder gauge shown in Fig. 29 is designed for testing parallelism, out of roundness, wear, &c., in cylinders from 6in. to 12in. in diameter, and as the dial is always outside the cylinder under test, the reading given by the pointer is easily observed. If the cylinder gauge is calibrated with a micrometer or by applying it to a cylinder of known diameter, it can be used for measuring the actual diameter of cylinder bores. The firm's ship's synchronised chronometer time control equipment occupies a prominent position on the stand. Electrically wound master clocks (as shown in Fig. 30), with full chronometer escapements, and as now fitted to a large number of vessels which do not carry a chronometer, are on view, together with chronographs of the tape and dial types.

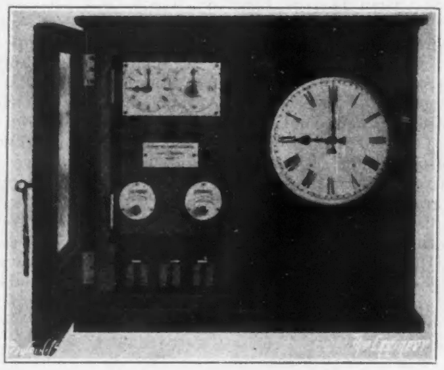

FIG. 30—MASTER CLOCK AND AUTOMATIC CONTROL PANEL—MERCER

AILSA CRAIG, LTD.

The exhibit of marine propelling and electric generating sets shown by Ailsa Craig, Ltd., of Strand-on-the-Green, London, W.4, serves to illustrate the great advance which, during the past few years, has been made by the firm in the design and construction of heavy-oil and paraffin-petrol engines of the smaller powers. They are manufactured in standard units having from one up to eight cylinders, in powers ranging from 6 B.H.P. up to 140 B.H.P. The heavy-oil engines operate on the four-stroke, airless-injection principle, and utilise a compression-ignition system of the Auro type with an air cell in the piston crown, to which the injection nozzle in the cylinder head is inclined at an angle of about 60 deg. The principle adopted was fully described and illustrated in our issue of September 11th, 1931. These Ailsa Craig heavy-oil engines are manufactured in two series, one with a cylinder bore of 3⅞in. and a stroke of 5½in., and the other with a cylinder bore of 4⅛in. and the same 5½in. stroke. They can be supplied either as direct-drive sets, or with standardised reduction and reverse gears of the firm's own design. A constructional feature is the large size of the crank shaft, which, in the case of the 3⅞in. cylinder bore engines, has a diameter of 2⅝in. The main bearings are long, the total length being 8½in. for the two-cylinder model, 14in. for the four-cylinder engine, and 19in. for the six-cylinder unit. The bearings shells are gun-metal, and they are lined under pressure with white metal. Special cast irons and alloy steels are used for the framing and running parts of the engine. The fuel pumps, injectors, and fuel filters are of the Bosch pattern, and the fuel pump is governor-controlled, giving a speed range of 1400 down to 220 r.p.m., according to the position of the hand-control lever. The starting arrangements embody some special features, and although the engines can be equipped with electric starting motors when desired, they can quite readily be started by hand in the smaller sizes especially.

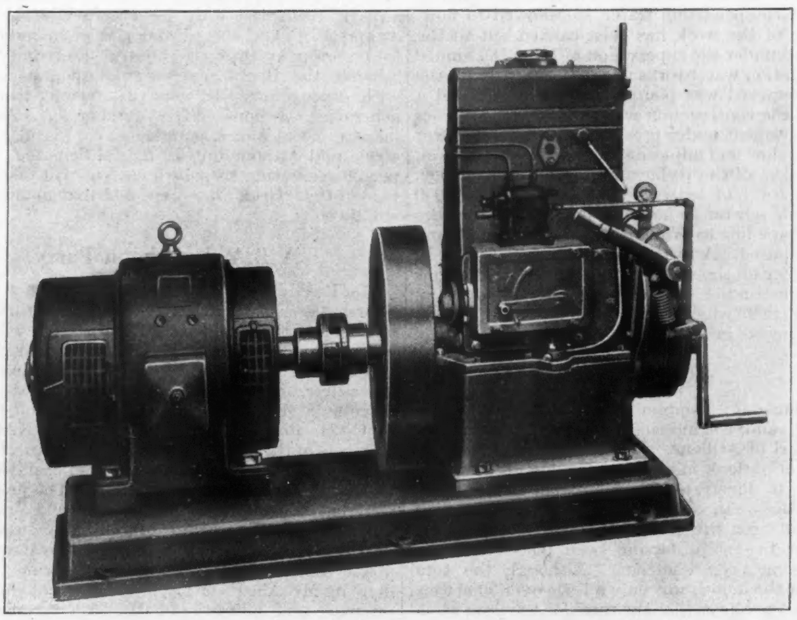

FIG. 31—10-kW OIL ENGINE-DRIVEN GENERATOR SET—AILSA

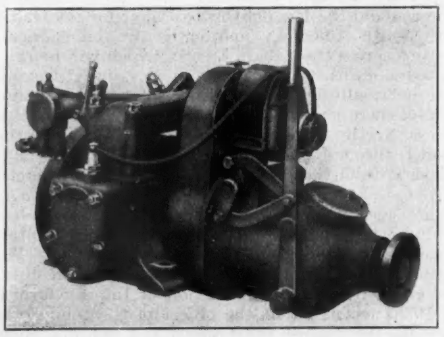

FIG. 32—4-6 B.H.P. MARINE PETROL ENGINE—AILSA

On the side of the valve rocker cover there is arranged a compression release lever, which has three positions, "no compression," "running position," and "over-compression." When it is desired to start the engine, the lever is moved over to "no compression" and the fuel pumps set for full speed. As soon as the engine has been turned over to give the fly-wheel sufficient momentum, the lever is thrown right over to "over-compression," and the valve setting corresponding to this position gives the special high-compression pressure for ensuring a prompt start. The lever is brought back to the normal running position when the engine has run up to speed.

We have chosen for illustration in Fig. 31 a twin-cylinder 12–20 B.H.P. engine mounted on a common bed-plate with a 10 kW generator. This view clearly illustrates the fuel pump, which is mounted on the cam shaft gear-box, and is furnished with an injection advance and retard lever. The lever shown to the right in the inclined position is the hand control for the governor, while the starting handle is also indicated. The engine is fitted with forced lubrication, and has an excentric-driven plunger pump for circulating the cooling water. Another exhibit of interest is the twin-cylinder 4–6 B.H.P. water-cooled, horizontal, opposed-piston petrol engine, illustrated in Fig. 32, which has been specially designed for the propulsion of small boats and for providing auxiliary power in yachts up to 5 tons. This engine has 2⅜in. bore cylinders, with a stroke of 2½in., and is designed for a running speed of 1000 to 2000 r.p.m. The petrol engines shown by the firm include a four-cylinder, 12–20 B.H.P. engine, with a special turbulence combustion chamber in the cylinder head, which has been designed for the utilisation of the cheaper grades of petrol fuel. Alongside the complete engines, some of which are shown in operation, a series of component parts is on view.

LACY-HULBERT AND CO., LTD.

The principal exhibits shown on the stand of Lacy-Hulbert and Co., Ltd., pneumatic engineers, of Boreas Works, Beddington, Surrey, is a series of portable air compressors, including both electric and petrol engine-driven units, along with auxiliary pneumatic equipment and air-operated tools. In the drawing reproduced in Fig. 33 we show a section through one of the firm's latest types of air compressors. It is equipped throughout with ball and roller bearings and is water cooled by means of a hopper and a fan-cooled radiator. The drawing shows the arrangement of running parts and the manner in which the valves are cooled. A compressor of this type is also illustrated in Fig. 34, which shows a modern type of paint spraying plant, or portable compressor unit for the operation of small pneumatic tools. Our engraving shows the unit coupled to a paint container and spraying pistol. The compressor is driven by a 3 H.P. Lister 1250 r.p.m. petrol engine, which is complete with a speed governor, fuel tank, exhaust silencer, and self-contained radiator and fan unit. The lower frame is designed as an air receiver and carries a pressure gauge, a pop safety valve, with drain cocks, and hose connections. The unit is mounted on a pair of strong wire wheels with 26in. by 3½in. Dunlop tires, which facilitate easy transport. A removable draw handle forms part of the equipment and there is a rubber shod foot giving three-point suspension when the unit is standing.

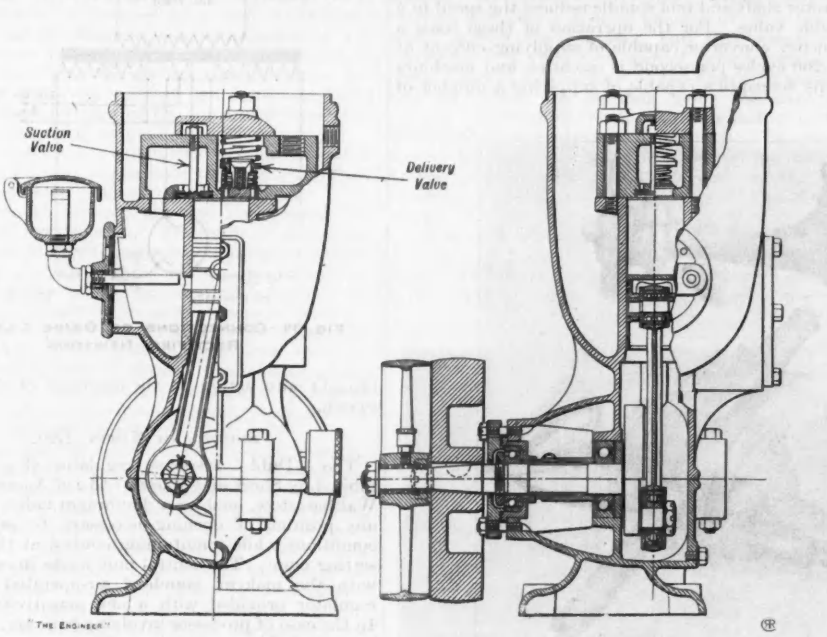

FIG. 33—SECTIONAL DRAWINGS OF SINGLE-CYLINDER COMPRESSOR—LACY-HULBERT

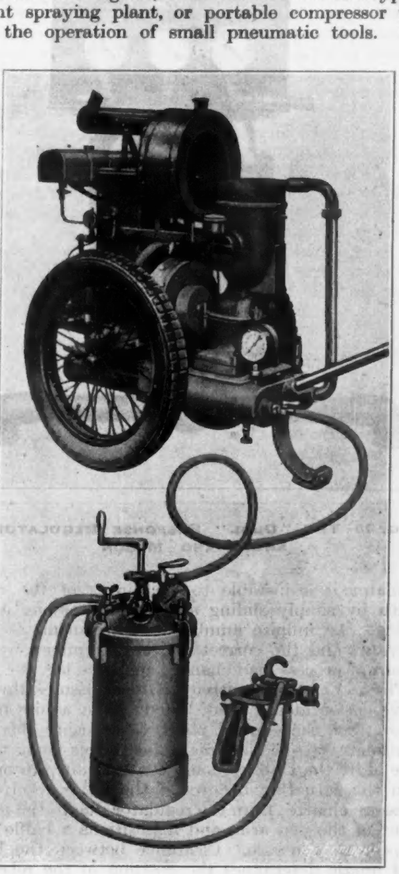

FIG. 34—PAINT SPRAYING EQUIPMENT—LACY-HULBERT

Another recent product of the firm is the small air-cooled compressor illustrated in Fig. 35. In the matter of main bearings and connecting-rod bottom end design it closely follows the design of the unit illustrated in Fig. 33. It has, however, been specially built for a variety of duties, such as tire inflation, thermostatic control, and other similar services which call for a small machine of proved reliability.

At the Exhibition a No. 1 automatically controlled air compressor set, of which there are four sizes, with designed outputs from 3 up to 12 cubic feet capacity, is shown. For such duties the air compressor is driven by a small electric motor and V-shaped belt, an automatic switch and valve gear being provided, which stops the compressor as soon as 130 lb. has been reached and starts it again when the pressure falls to 110 lb. per square inch. The whole of the equipment is mounted over a riveted air receiver of circular shape, which is designed and tested for a working pressure of 300 lb. per square inch and a working pressure of 150 lb. The firm is also showing a range of Boreas patented rotary pumps for lifting circulating water and oil, suds, brine, petrol, &c. It has also worked out a method of tire inflation for garages utilising a high-pressure air receiver at 1800 lb. and parts of this equipment are on view on the stand.

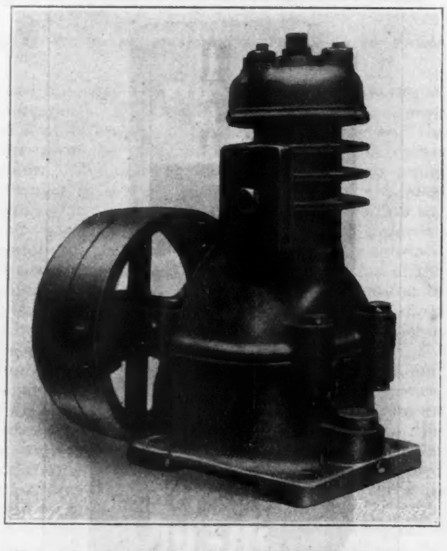

FIG. 35—SMALL AIR-COOLED COMPRESSOR—LACY-HULBERT

SHEEPBRIDGE STOKES CENTRIFUGAL CASTINGS COMPANY, LTD.

Castings in a number of alloy cast irons manufactured by a patented centrifugal casting process are shown by the Sheepbridge Stokes Centrifugal Castings Company, Ltd., of Sheffield, besides many others cast in sand. In making centrifugal castings the firm utilises permanent metal moulds rotating at high speed and no sand is necessary. The castings shown are arranged to demonstrate the properties of the alloys from which they are made, as the firm is particularly concerned with the production of alloys with special qualities, such as resistance to wear, to heat, and to corrosion. Of these alloy cast irons Centricast Mark IV., which is a low-silicon grey iron alloyed with nickel, has a tensile strength of 16 to 22 tons per square inch and a Brinell hardness figure of 275–300 in the as-cast condition. Its special quality is that its wear-resisting properties may be much improved by quenching in oil from a temperature of about 850 deg. Cent. and subsequent tempering in a salt bath, a hardness figure of 450–500 throughout the section being obtainable. The material thus produced is suitable for cylinder liners, valve bodies, gears, bushes, dies and moulds, &c. Another interesting alloy cast iron is known as Hypocrode. Its composition for most purposes is 12 to 15 per cent. nickel, 6 to 7 per cent. copper, and 1·5 to 5 per cent. chromium, and it is essentially austenitic in character. This material may be cast into intricate shapes with an absence of any tendency to porosity and being resistant to erosion and the corrosive action of acids and alkalies, is suitable for hydraulic parts of many kinds, such as pump barrels, plungers, liners, &c. Since it also has a high resistance to distortion under heat conditions and to growth at high temperatures, another field of usefulness is also available, and it may be used for furnace parts, stoker parts, ingot moulds, &c. Such castings are to be seen on the stand. Some of its physical properties as given to us by the makers are shown in the table below.

Tensile strength..	14 to 16 tons per square inch
Elongation	1½ to 2 per cent. on 2in.
Modulus of rigidity	$13–18 \times 10^6$ lb. per square inch
Specific gravity	7·5 to 7·6
Coefficient of thermal expansion	$1·8–1·9 \times 10^{-5}$
Thermal conductivity	0·08
Electrical resistivity	135 to 140 microhms per c.cm.
Temperature coefficient of electrical resistance (0 deg. to 100 deg. Cent.)	0·00045
Magnetic permeability	1·03 to 1·05
Brinell hardness	140 to 300, as required

The firm also manufactures under licence the Silal and Nicrosilal alloys, invented by the British Cast Iron Research Association.

THE MARCONI INTERNATIONAL MARINE COMMUNICATION COMPANY, LTD.

A comprehensive display of new wireless apparatus, including the latest installations for telegraphy and telephony and music playing, is to be seen on the stand of the Marconi International Marine Communication Company, of Electra House, Victoria Embankment, W.C.2. The exhibits are arranged both to facilitate the examination of apparatus and to indicate the space required for wireless equipment of various kinds on different classes of vessels. The installations are fitted in three cabins, in one of which the most recent of the largest wireless telegraph installations for use on ships is shown. The installation includes a 2 kW transmitter capable of communication on long, medium, and short wavelengths. Switches facilitate the change over from one unit to the other, and connect the appropriate aerial to the transmitter to be used, so that the operator can transmit on any desired wavelength with a minimum amount of trouble. An emergency transmitter as required by international regulations is included in the installation.

In the two smaller cabins there is wireless apparatus for cargo ships, yachts, and trawlers, &c. The installation for cargo ships includes the most recent types of medium and short-wave transmitters which meet the requirements of recent International Conventions. On modern cargo ships the conditions may be very exacting. Not only is an efficient service required on the medium wave band over distances up to 500 or 600 miles, but very long ranges of transmission reception may also be necessary. On account of the fact that the space on these vessels is very limited, the Marconi Company has designed two sets which either work separately or in conjunction with one another. Provided the vessel is fitted with both medium and short-wave transmitters of this type, ranges can be obtained up to 500 or 600 miles on the medium-wave transmitter, and over 3000 miles on the short-wave transmitter. As the receiver incorporated in this transmitter covers a wave band of from 15 m. to 20,000 m., it is suitable for working in conjunction with either transmitter, and apart from the fact that the refinements necessary for passenger service have been omitted, it is similar to that employed on large passenger vessels.

As it is sometimes impossible to employ a skilled operator on trawlers, yachts, tugs, fishing boats, &c., the company has introduced simple and efficient transmitters which can be used for communication by telegraphy or telephony. A skilled operator on craft of this nature is, therefore, not absolutely essential. Designed for single-knob control, the transmitters are said to be capable of withstanding the most strenuous conditions met with on small vessels. A battery driving a small D.C. generator provides the high-tension supply. The receivers, which, like the transmitters, are very robust, cover a waveband of from 100 m. to 2000 m.

Shipowners will no doubt be interested in the Marconi wireless telephone set for communication with the wireless telephone stations established by the Post Office in British waters. The apparatus has been designed for use without an operator on yachts and other small craft on which space is restricted, but larger telephone installations capable of meeting more extensive requirements are, of course, available for other ships. Since the receiving equipment for use with the telephone installations covers all the normal broadcast wavelengths, as well as the special marine telephone wave band, weather reports, news bulletins, and other broadcast information can be obtained in almost any part of the world.

E. Green and Son, Ltd.

Besides a vertical tube economiser consisting of forty-eight tubes 9ft. long, a Foster economiser of twenty-four elements 12ft. long and a cast iron oval tube air heater, the firm of E. Green and Son, Ltd., of Wakefield, is showing an "Eco Minor" dry cleaning machine. The construction of the first-named devices has been often described and to the majority of engineers the general details will be familiar, but the dry cleaning machine, which is manufactured by the firm's subsidiary undertaking, Eco Power, Ltd., of 15, Lincoln's Inn-fields, London, is less well known. It is a compact unit for cleaning clothes and textile materials of all kinds in a non-inflammable solvent. For none of the operations of washing, extracting the solvent, or drying is it necessary to open the doors once the machine has been loaded until the goods are completely dry cleaned and deodorised. Owing to this totally enclosed feature it is possible to recuperate and use the solvent over and over again, the loss which has to be made up occasionally being almost negligible. An interesting feature of the device is that the solvent is not merely non-inflammable, but actually a fire extinguisher. The device may be installed in any shop or building and on board ship.

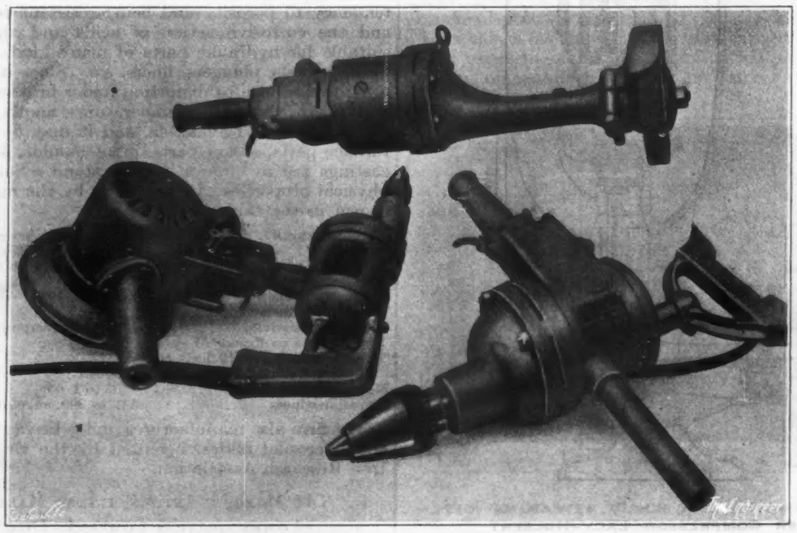

Fig. 36—High Frequency Electric Tools—Newtons

Newtons of Taunton, Ltd.

Electric tools of various kinds, such as drills, grinders, sanders, polishers, valve refacers, &c., are being shown by Newtons of Taunton, Ltd., of 319, Regent-street, W.1. Besides tools fitted with universal motors for A.C. or D.C. and suitable for use on ordinary supply circuits, there are special high-frequency tools, as shown in Fig. 36. The motors fitted to these tools consist of a three-phase field system and a squirrel-cage rotor mounted in ball bearings. The advantages of these tools are greatly increased power, reduced weight, simple construction, and constant speed. The absence of a commutator and brushes eliminates trouble, whilst the greater power-weight ratio facilitates operation and reduces fatigue. The field coils are wound with enamelled and silk-covered wire, whilst the rotor conductors consist of solid copper bars. The rotor is dynamically balanced, and a fan on the shaft serves to ventilate the machine. Gearing between the rotor shaft and tool spindle reduces the speed to a suitable value. For the operation of these tools a frequency converter capable of supplying current at 180–200 cycles per second is essential, and machines of this description capable of supplying a number of tools are made at Taunton, the tools themselves being constructed at the firm's "Rotax" Works, Willesden. At present these high-frequency tools consist of drills, sanders and grinders, but other tools are being developed for reaming, tapping, stud setting, nut driving, &c.

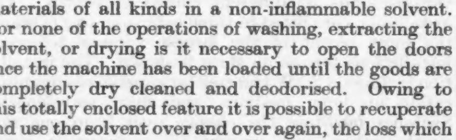

Fig. 37—Oxide Cathode Rectifier—Newtons

Mercury arc and Newton oxide cathode rectifiers, as shown in Figs. 38 and 37 respectively, are also exhibited. The latter is said to be from 25–30 per cent. more efficient than a motor generator and slightly more efficient than the average mercury arc rectifier. Oxide cathode rectifiers are eminently suitable for cinema work. There are no moving parts, ignition, or exciter devices. The average life of the valve is said to be two years and the cost of renewal is considerably less than that of a mercury arc bulb. Exceptionally good voltage regulation is another advantage claimed for these rectifiers. The valve is of the hot cathode gas-filled type, which in its simplest form consists of a filament of barium oxide and two graphite anodes contained in the gas-filled bulb, the filament being heated with A.C. derived from a heating winding on the main transformer, as shown in Fig. 39. As will readily be appreciated by those familiar with rectifiers, the provision of the two anodes enables the apparatus to give full-wave rectification.

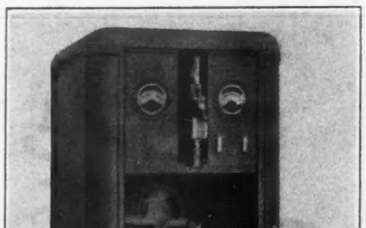

Fig. 38—Mercury Arc Rectifier—Newtons

In the case of the mercury arc rectifier the filament is, of course, replaced by the mercury arc pool, and to start the apparatus an auxiliary arc is formed on the pool in order to establish an electron flow from the mercury to the anodes, this being done by means of an auxiliary exciting circuit, which is automatically brought into action on the operation of the control switch.

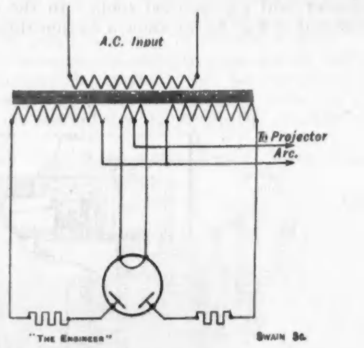

Fig. 39—Connections of Oxide Cathode Rectifier—Newtons

Short and Mason, Ltd.

The "Dubl" response regulator (Fig. 40), exhibited by Short and Mason, Ltd., of Aneroid Works, Walthamstow, enables a diaphragm valve to assume any position of opening necessary to satisfy load conditions while maintaining control at the original setting point. The control unit works in conjunction with the makers' standard air-operated recording regulator provided with a new sensitivity reducer. In the case of processes involving time lag, an instrument with high sensitivity will cause a conventional valve to hunt as the process apparatus cannot absorb changes in the controlled medium as rapidly as the valve responds to the pen movement. The new sensitivity reducer now built into the recording regulator is adjustable to the limits of the chart width by simply sliding a clamp unit along a flat spring. An infinite number of adjustments is thus provided and the correct one is determined by the extent of process load changes and time lag.

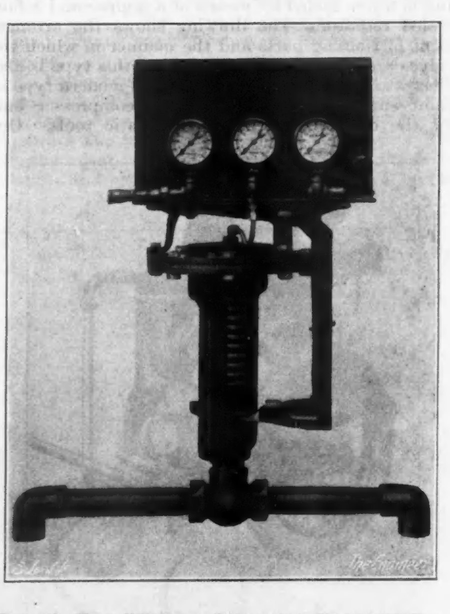

Fig. 40—The "Dubl" Response Regulator—Short and Mason

The use of the sensitivity reducer assures throttle valve action at any load, but does not assure maintenance of the control point when using the conventional type of diaphragm valve, this being taken care of by the Dubl response control unit. In operation the actuating bellows of the latter receive air pressure changes from the regulator due to the movement of the pen arm, and it positions a baffle with respect to a nozzle. Clearance between the baffle and nozzle determines the position of the relay air valve and therefore the air pressure admitted to the diaphragm valve. Increased pressure drives the valve stem downwards and the push rod upwards. At its lower end the push rod is attached to a pivoted lever in contact with the valve stem just above the stuffing-box and at the upper end to the nozzle blocks. Responsive movement of the valve stem is therefore exactly proportional to the baffle movement, since it must continue until the baffle-nozzle clearance is correct. This is the initial valve response operation, and is proportional to the movement of the pen arm from the control setting. By the time the process has begun to take advantage of the initial valve movement a second response action is started by the Dubl response mechanism.

This action is independent of the pen arm position. It is associated with the damping device, and the pivoted levers connected to the baffles, and determines the final position of the valve within extremely fine limits. The damping device consists of bellows filled with liquid, and is adjustable to match the approximate time lag of the process, or, in other words, the delay between the change in input of the controlled medium and the response of the regulator. The damping device is arranged on a slide so that the magnitude of the damping can be adjusted on site to synchronise with the time lag and load change in the same way that the sliding clamp unit in the pneumatic sensitivity reducer can be synchronised with the characteristics of the apparatus concerned to give full throttling action.

Another exhibit is a volumetric pressure recorder, which resembles in appearance the firm's standard mercury operated recording thermometer. The major difference between the two instruments lies in the bulb construction. The bulb of the volumetric pressure recorder responds to pressure instead of temperature, and the principle involved therefore differs from that of the temperature recorder. In addition to the bulb or pressure responsive element, the power unit or tube system consists of the connecting tubing and a hardened fine bore steel Bourdon spring welded together to form a hermetically sealed system, which, except for the space in the bulb occupied by a special alloy temperature compensating element, is filled with mercury.

When the bulb is subjected to external pressure, its volume is reduced as the applied pressure increases, and some of the mercury it contains is forced into the tubing, and so causes the Bourdon spring to uncoil. Conversely, when the pressure on the bulb is reduced, its increased volume permits mercury to flow back into it, and the Bourdon tube returns to its original position. Instead of the operation of the Bourdon spring being caused by the increased volume of mercury due to its expansion under the influence of heat, the operation of the spring is caused by displacement of the mercury from the bulb as a result of the change in its dimensions under the influence of pressure. On account of the temperature compensation employed, the volumetric pressure recorder only responds to changes in pressure around the bulb. By means of the special alloy compensating element inserted in the bulb, the difference of expansion of the bulb equals the expansion of the mercury produced by temperature; whilst the temperature effect of the remaining part of the system is compensated for in the usual way by means of a bimetallic compensator. The principle of operation lends itself to the measurement of high pressures under conditions which make the conventional type of Bourdon gauge inapplicable.

The makers inform us that owing to the pulsation-proof operation and the fact that the liquid under test does not enter the Bourdon spring, the instrument, which can either indicate or record the pressure at a remote point, has so far found the widest field of application on homogenisers which demand in general a pressure range of 0–5000 lb. The same principle has been incorporated in a tension type of bulb, which finds application where a cable or other tension load has to be recorded or indicated.

HYDRAULIC COUPLING AND ENGINEERING COMPANY, LTD.

Hydraulic couplings have become familiar to the public by reason of their use upon motor cars, but in actual fact their applications are far less limited than that. To those interested in such devices a visit to the stand of the Hydraulic Coupling and Engineering Company, Ltd., of Worton-road, Isleworth, can be recommended. A photograph of a Vulcan-Sinclair traction-type coupling, showing the main parts, is reproduced in Fig. 41. The majority of our readers will be more or less familiar with its mode of operation. The oil contained within it is constrained to follow a helical path between the "pockets" of the two halves, and in this manner transmits the drive. Actually, the driven shaft may be completely stalled without causing the driving motor or engine to stop. Under such conditions the full torque is transmitted. At full speed and full load a slip equivalent to about 2 per cent. occurs. As we have already said, the use of hydraulic couplings in the traction field is already fairly well known. But with slight modifications it is also particularly suitable for other applications. When used for traction purposes a definite amount of oil is usually sealed within the coupling, and this quantity is invariable. If, however, special arrangements are made whereby the amount of the hydraulic medium may be varied, the coupling gains characteristics of very considerable value for such duties as the driving of centrifugal pumps and fans, &c. In general, it may be said that boiler feed pumps are usually driven by direct-coupled A.C. electric motors. The arrangement has certain disadvantages. The characteristic of a centrifugal pump running at constant speed is such that should it at maximum output develop just sufficient pressure to overcome that within the boiler, it will at lower deliveries develop a considerably higher pressure. Thereby there is caused not only a waste of power in overcoming an unnecessarily high pressure, but, also, the pipe work feed heaters and valves between the pump and the boiler must be designed to withstand the excess pressure. By coupling the motor and the pump hydraulically a much closer approach to the ideal condition at which the pressure at discharge into the boiler is constant can be obtained. In order to maintain the pressure of delivery at the boiler constant it is necessary to reduce the speed of rotation of the pump. At the same time, the speed of rotation of the A.C. motor must remain constant. This effect can be achieved by altering the amount of oil within the coupling according to the load on the pump.

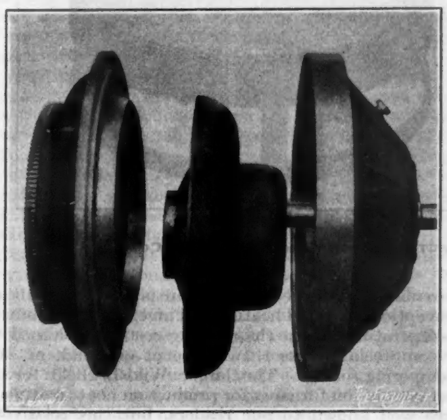

FIG. 41—VULCAN-SINCLAIR HYDRAULIC COUPLING

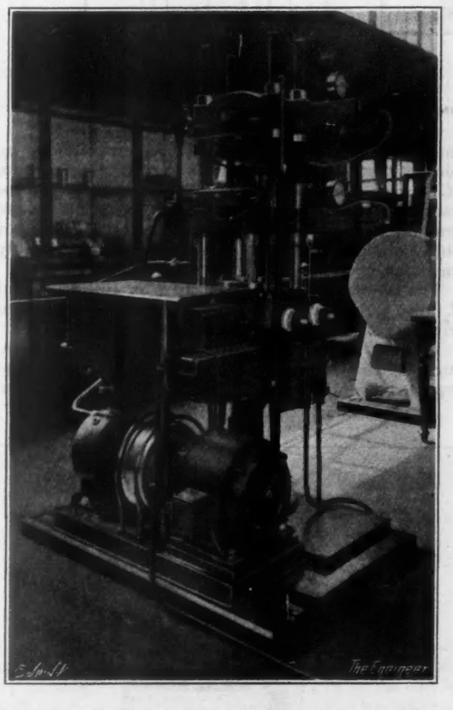

FIG. 42—COUPLING APPLIED TO HYDRAULIC PRESS

For the purpose of driving boiler feed pumps and also fans, which have very similar characteristics, the oil for the coupling is made to circulate from an overhead tank. It runs down by gravity to the coupling and is "scooped" out and returned to the tank through a separate pipe. As applied to feed pumps, there is an automatic regulating valve in the oil supply pipe. When the feed pressure tends to rise, owing to the boilers requiring less water, a servo-cylinder operated by the feed pressure partially closes the regulating valve, thereby partially starving the coupling of oil. The slip, therefore, increases and the pump speed is reduced, although the motor speed remains constant. Thus the pressure may be maintained very nearly constant. Since pressure oil for the operation of the servo device can be obtained from the scoop tube, the set may be self-contained.

Another application of the coupling is illustrated in Fig. 42. Here it is interposed between a motor and a positive rotary pump supplying oil for the operation of a hydraulic press for bakelite and similar plastic substances. The operation of such presses demands a considerable period during which the pressure is maintained without any motion. Thus during the first stage, when the material is being forced into the die, the coupling acts with little slip, and the pump is rotating at nearly the same speed as the motor, and during the second stage, the pump is almost or completely stalled, the slip becomes 100 per cent., and by reason of the characteristic of the coupling the pressure is maintained.

F. J. EDWARDS, LTD.

Among the newer sheet-metal working machines exhibited by F. J. Edwards, Ltd., of 406, Euston-road, London, N.W.1, there are the angle bender and the cramp folding machines illustrated by Figs. 43 and 44.

The former, it will be seen, is of the hand-operated type, and its top beam is pivoted at one end, while the other end is held by a square notch. As a consequence, it can be swung out and any enclosed form which has been bent around it can be slipped off endways without deformation. The beam is locked in position by a pin, while the bending is being done. An adjustable back gauge is provided for repetition work, and the end frames have openings so that long, narrow strips of metal can be fed through and formed by the length of the table at each stroke. The machine is made in several sizes with widths ranging from 20½in. up to 48½in., and is intended for working mild steel sheets of from 20 to 18 gauge. The cramp folding machine (see Fig. 44) is so arranged that the work can be passed right through the gap between the clamping beams, so that bends can be made at any part of the length of the sheet as well as the edges. Gauges are provided for locating the sheet when bending narrow edges, but they can be removed when longer folds are required. The top beam can be lifted clear by means of an excentric shaft to allow bent or shaped sheets to be inserted, and the front (bending) beam is provided with a stop to ensure the angle of the bend being repeated. The corner can be made either sharp or with a radius. The machine is made in five sizes for sheets from 26in. to 48½in. wide.

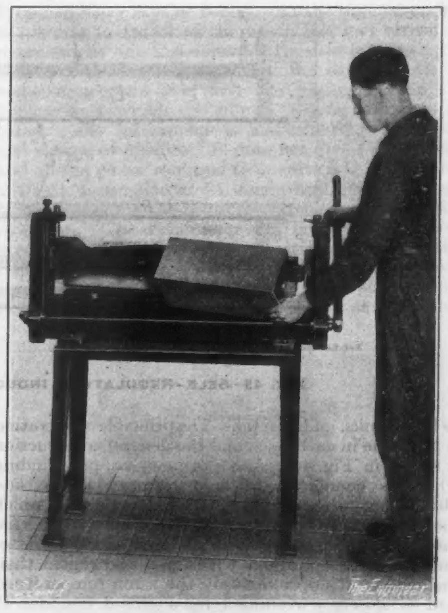

FIG. 43—SHEET METAL BENDER—EDWARDS

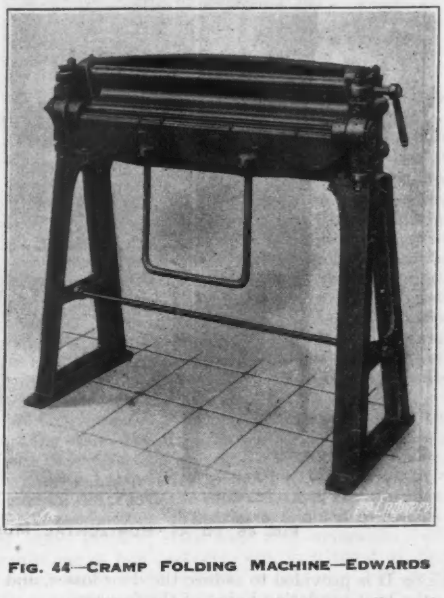

FIG. 44—CRAMP FOLDING MACHINE—EDWARDS

ELECTRIC RESISTANCE FURNACE COMPANY, LTD.

Self-regulating normal frequency induction furnaces for heat treatment and low-temperature metal melting are shown by the Electric Resistance Furnace Company, Ltd., of 17, Victoria-street, S.W.1. The temperature is controlled by bars composed of a special alloy supplied for maintaining the furnace temperature at any value between 400–1000 deg. Cent. When the desired temperature is reached these bars lose their magnetism, and the input to the furnace is immediately diminished, until the bars regain their magnetism, when the load is automatically increased.

Four types of these furnaces are available: (1) Muffle furnaces for general heat treatment purposes; (2) low-temperature melting furnaces for aluminium, lead, type metal, &c.; (3) balanced furnaces for precision heat treatment of press tools, &c., and (4) continuous heating furnaces for small objects such as bolts, links, gudgeon pins. The principle of operation is the same in each case, and the general construction is shown in Fig. 45. A is a primary copper winding which is connected to any ordinary low-tension alternating current supply; B a magnetic core, which may constitute the furnace muffle, or may be inserted into the muffle in the form of bars. It is made of one of a series of alloys which lose and regain their magnetism at approximately the same temperature, and is closely surrounded by a closed cylinder C, which is substantially non-magnetic at the working temperature. B^1 is a laminated iron core which completes the magnetic circuit. A heat-insulating lining D is provided to reduce the door losses, and E is the heat-insulating lining of the furnace.

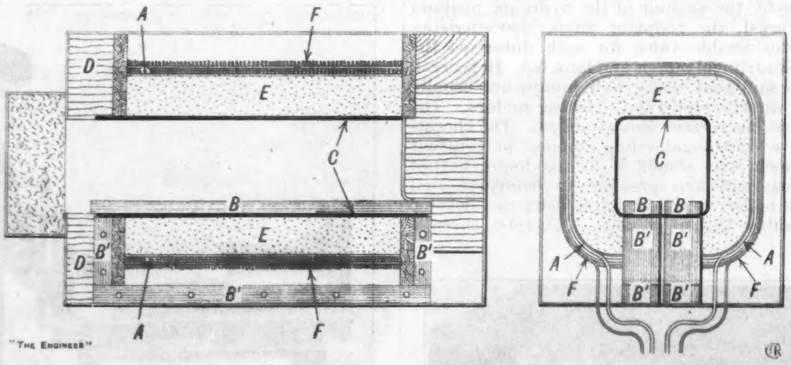

FIG. 45—SELF-REGULATING INDUCTION FURNACE—E. R. FURNACE CO.

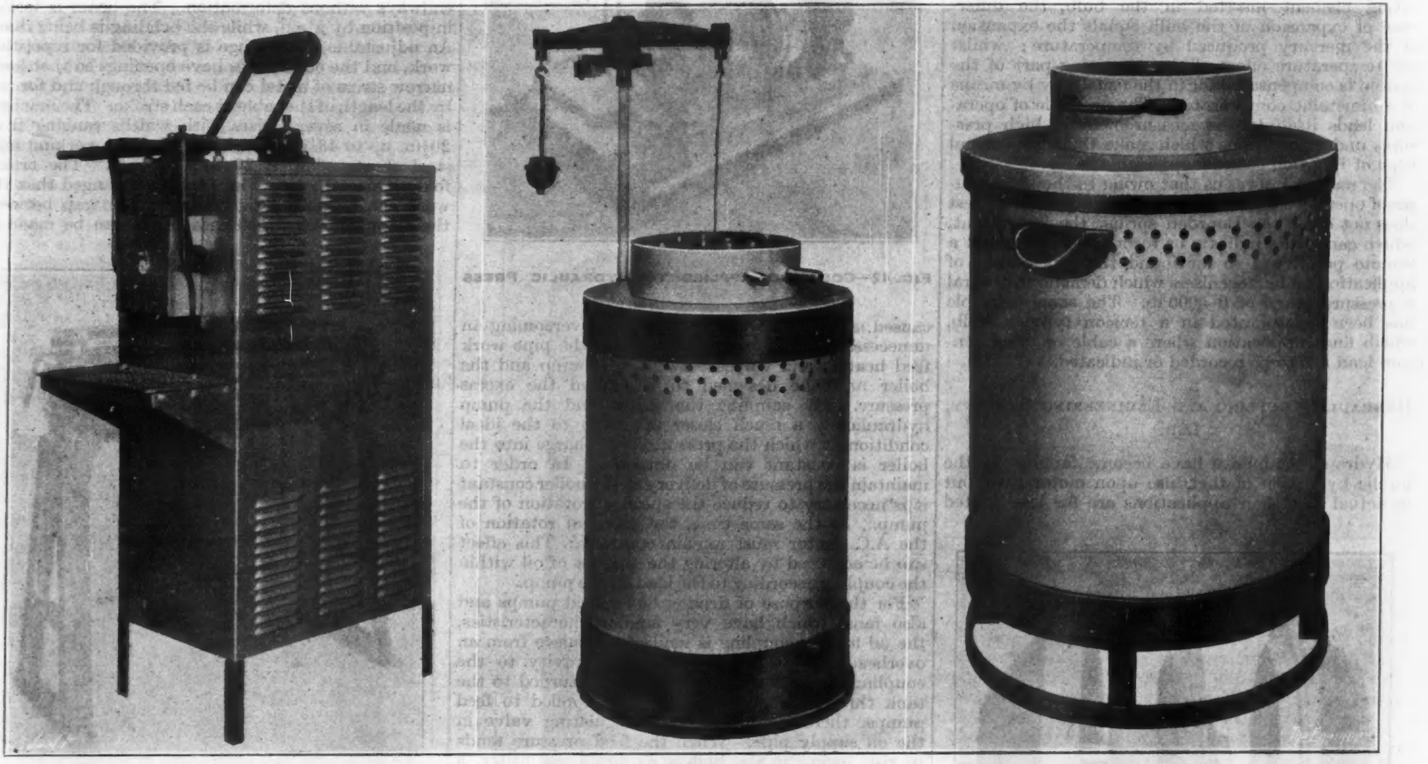

FIG. 46 TO 48—HORIZONTAL MUFFLE, VERTICAL MUFFLE, AND CRUCIBLE FURNACES—ELECTRIC RESISTANCE FURNACE CO.

The coil A acts as the primary of a transformer, of which the cylinder C is the short-circuited secondary and B and B^1 the core. Current induced in the cylinder C causes it to be heated, and the heat passes by conduction to B, which, at a certain temperature, loses its magnetism. This reduces the flux through the core to such an extent that insufficient heat is generated in the cylinder C to compensate for the losses by radiation, &c., and the temperature of B accordingly falls until it reaches the point at which it regains its magnetism. The induced current then increases and the temperature of the cylinder C again begins to rise, the small amount of heat generated in B by eddy currents being insufficient to interfere with the cycle described above. In some cases an additional copper coil F and a condenser are provided for power factor correction, but, generally speaking, these are unnecessary. As there is only a small difference of temperature between the points at which the ferro-magnetic material loses and regains its magnetism, the control of temperature is very close.

Furnaces constructed on this principle are claimed to possess many important advantages as compared with resistance furnaces heated by elements of nickel chrome or other similar alloys. The temperature remains practically constant without the use of any control instruments, and as the muffles are made of special steels instead of refractory material, the furnaces are very robust. Short circuits by contact between the charge and the resistors are, of course, eliminated. The rate of heating can be varied within wide limits, and as the variations are gradual instead of instantaneous, the load is not objectionable from the point of view of supply undertakings.

The power factor is about 0·8 on full load, but if unity power factor is required, it can be obtained with a condenser connected to the coil F.

When it is desired to change the working temperature of the furnace, the self-regulating bars are replaced by others of different composition. Regulator bars in different parts of the furnace can have a different composition in order to provide a predetermined variation of temperature along the length of the muffle in order to meet the requirements of heat treatment operations. The makers also explain that it is impossible for a furnace to "run away," owing to failure of control gear, and so damage the charge that is being heat treated.

A self-regulating horizontal muffle furnace for tool hardening and general work is shown in Fig. 46, and a vertical muffle furnace in which the charge to be treated is suspended on one arm of a simple balance in Fig. 47. The charge in this case must be magnetic, and use is made of its magnetic change point. When this point is reached the attractive force is removed and the out-of-balance condition causes the charge to move upwards in the furnace, and a small switch on the arm closes an alarm circuit. The self-regulating elements consist in this case of a hollow cylinder or a number of bars placed inside the secondary conducting muffle, and retained in position by a cylinder of non-magnetic material. In addition to simple heat treatment processes these vertical muffle furnaces are suitable for precision processes. Fig. 48 shows a 5 kW crucible furnace for melting lead, aluminium, &c.

WILD BARFIELD ELECTRIC FURNACES, LTD.

Among the exhibits of Wild Barfield Electric Furnaces, Ltd., of Elcfurn Works, North-road, Holloway, N.7, is a new tool-room tempering equipment, as shown in Fig. 49. Air is circulated by a centrifugal fan in a closed circuit over the heating elements, and through the work under treatment, so that the heat is conveyed from the source to the charge much more rapidly and with greater uniformity than would be possible with still air. The powerful circulation produced by the fan is said to result in exceptionally rapid heating and an extremely uniform temperature, whilst the running costs are claimed to be appreciably less than those of oil, lead, or salt tempering baths. The larger Wild-Barfield forced air circulation furnaces for production heat treatment are well known to our readers, but this relatively small furnace has been introduced to meet the demand for an equipment suitable for tempering carbon and alloy steels, and the secondary hardening of high-speed steel tools in the tool-room.

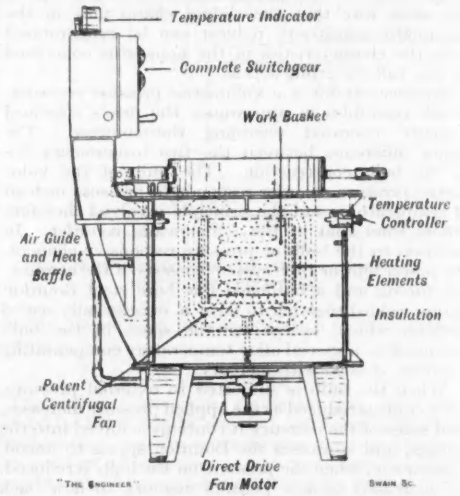

FIG. 49—TOOL-TEMPERING EQUIPMENT—WILD BARFIELD

While compact, and occupying little floor space, the furnace is equipped with automatic temperature control gear, a temperature-indicating instrument, and a switch panel fitted with pilot lights. Refinements, such as the charge progress recorder, as fitted to the larger production furnaces, are not, however, provided as standard accessories, as they are not essential for ordinary tool-room work. The new furnace is made in two types, one suitable for temperatures up to 400 deg. Cent., and the other up to 650 deg. As far as the construction is concerned, both furnaces are identical, the only difference in the two being the design of the temperature regulator. While the low-temperature model is suitable for tempering carbon steel parts, the high-temperature unit will cover the whole range of tool-room tempering. The maximum rating is 4 kW, but a consumption of 1½ units per hour serves to maintain the temperature at the highest value.

In order to combine rapid initial heating with close temperature control, a switch on the control panel serves for cutting out one section of the heating elements, and by thus reducing the furnace rating exceptionally close control is said to be secured even at temperatures extending down to 200 deg. Cent. The most expensive dies, press tools, milling cutters, &c., can be treated without risk of damage. In the design of these equipments the utmost simplicity has been aimed at. All connections between the furnace and its associated electrical gear are made at the works, and after the user has connected up the supply leads to the switch panel, the furnace is ready for use.

The Walter Kidde Company, Ltd.

Two types of fire-detecting equipment for ships are exhibited by the Walter Kidde Company, Ltd., of Hanwell, London. The two systems are known as the "Selex" and the "Zonit" respectively, and differ in the respect that while the first gives an indication on the bridge or in a separate fire station of the exact location of the fire, the latter only indicates the "zone" in which the fire has occurred. For the actual detection of the fire, thermostatic switches, operated by Grinnell quartz bulbs, are used. These quartz bulbs, it will be remembered, enclose a quantity of a special non-freezing non-corrosive liquid, and at normal temperatures a small bubble of air. As the temperature rises the air bubble is compressed until finally, on its complete disappearance, the pressure becomes great enough to shatter the bulb. In the fire-detecting systems under review, this occurrence causes electric contacts to open or to close.

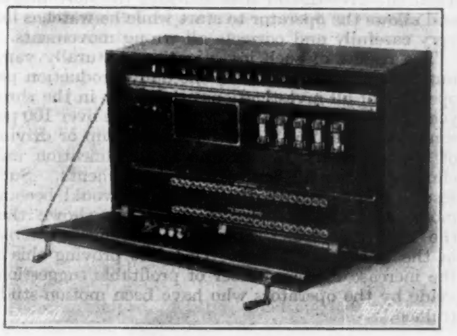

Fig. 50—"Zonit" Fire Detector—Kidde

These units are common to both "Zonit" and "Selex" systems, the former of which, owing to its greater simplicity, will be described first. In this system a number of thermostats are connected in series. For instance, in each of a group of cabins situated close to one another, there would be one thermostat. All the units would be connected in series, the wire beginning and ending at the control cabinet on the bridge. There would be several separate circuits, one for each zone. In passageways and gangways a manual alarm, operated by the breakage of glass, could be substituted for the automatic thermostat.

On the occurrence of a fire in any cabin, the thermostat operates to break the circuit and causes a relay in the control cabin to operate. A gong is then rung and continues to ring until attention is paid to it. To discover the zone in which the fire is situated, the front of the cabinet is opened, as shown in Fig. 50, and all the switches in the top row are depressed. This action causes the gong to cease ringing, since alternative circuits to those provided *via* the thermostats are then put in action. The switches are next raised one by one. Only those which cause the gong to ring when raised are left in the lowered position. These switches indicate the zone or zones that must be examined for the fire. Closing the door of the cabinet automatically raises all the switches.

It will be appreciated that should an "earth" occur, the whole system might be made inoperative. To guard against any such happening, a "buzzer" is arranged to sound if there is an "earth" in any circuit. Then by operation of the lower row of switches, the circuit thus affected can be discovered and the fault subsequently rectified. The "buzzer" also sounds should any other trouble occur. For testing the circuits there is in each a test station containing a switch which may be opened by the operation of a key. The resulting action is exactly that occurring if a thermostat operates.

The "Selex" system is wired differently, and usually there are also two types of thermostat. The "selector" thermostats, which, on the bursting of the quartz bulb "make" a contact, are arranged across a two-wire system. In series with each there is a fixed resistance. "Non-selector" thermostats may be wired across "selectors." In this way the operation of a non-selector thermostat may be made to have the same result as the operation of the "selector." The two wires of the system are also connected by a large resistance. Altogether, each zone of the system may have a total of 49 "selector" thermostats. Thus with ten zones 490 cabins or rooms could be protected.

Normally a "trickle" of current limited by the resistance across the circuit is passing. On the operation of a thermostat, however, a considerably larger current flows. Its first action is to set ringing a gong in the control cabinet. At the same time a relay is set in motion and rotates a selector switch which brings into action in the internal circuit of the cabinet a resistance large enough to balance that of the external circuit. By this action there is set up on the central panel, to be seen in the engraving, Fig. 51, a key number for the position of the thermostat operating the circuit. Opening the cabinet door stops the ringing of the gong, but the key number is still displayed.

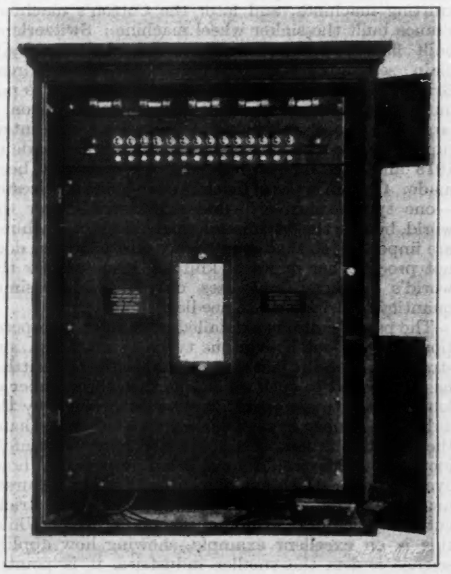

Fig. 51—"Selex" Fire Detector—Kidde

Both the "Selex" and the "Zonit" systems derive their electric current from the ship's supply, and, in addition, there are also accumulators capable, by themselves, of keeping the system in action for two days, and "trickle" charged from the mains.

Telephone Manufacturing Company, Ltd.

Noise proof telephones for use in ships, engine-rooms, and, in fact, in all places in which noise precludes the use of ordinary telephones, are being exhibited by the Telephone Manufacturing Company, of Hollingsworth Works, West Dulwich, S.E.21. There are also loud-speaking instruments of the horn and hand combination type and auxiliary apparatus, such as indicators, switches, plugs, sockets, &c. To prove the claim that ships' telephones can be used in very noisy places, a special cabinet has been erected on the stand to enable visitors to test the instruments under that condition. Other exhibits consist of inter-communicating telephones for use in offices and works and A.C. and battery operated synchronous clocks.

Black and Decker, Ltd.

A good display of portable electric tools is to be seen on the stand of Black and Decker, of Slough. There are drills ranging from ¼in. to 1¼in. capacity in steel, together with bench and post drill stands, portable electric screw drivers, and nut runners for driving screws into wood or metal, and for running on nuts respectively, portable electric sanders for sanding castings, &c., for cleaning welding seams, and for sanding and polishing boat hulls, car bodies, &c., previous to varnishing and enamelling. Other exhibits consist of portable electric grinders for fettling castings and forgings, electric buffers, valve refacers, and a collection of high-cycle electric tools. A high-cycle nut runner is shown in operation, and serves to demonstrate that these high-frequency tools are exceptionally light for their rated power. With the aid of a high-frequency nut runner every nut is made uniformly tight without the subsequent use of a spanner, and a special "quick-change" chuck makes it possible to use the same machine for nuts of various sizes with a minimum loss of time. When necessary, these nut runners can be provided with a reversing switch to enable the tool to be used to unscrew nuts, when, for example, machines are dismantled for shipment. Ball bearings are fitted throughout and the gears are composed of specially heat-treated steel. The machines are fitted with a positive clutch which disengages when the forward pressure on the tool is relieved. The motors are small, three-phase, squirrel-cage machines without a commutator or brushes, and are consequently very robust. A small motor generator on the stand converts the standard 50-cycle current into 180-cycle current for operating these tools.

The Marconi Sounding Device Company, Ltd.

Examples of the Marconi Echometer sounding device, as shown in Fig. 52, are being exhibited by the Marconi Sounding Device Company, Ltd., of Electra House, Victoria Embankment, W.C.2. By means of these instruments a ship is able to send out through the water to the sea bed a series of focussed high-frequency rays or beams, and the time taken for the beams to travel to the ocean bed and return is measured by the instrument. By merely pressing a button the navigator is shown the exact depth of water under the keel and the nature of the sea bottom over which the ship is passing is also indicated. The instrument is instantaneous in action and simple to operate. It does not give rise to noise and all the power required to operate it is taken from a 4-volt accumulator. A single hull casting serves to accommodate the projector, which is also used for reception. The Echometer can be operated simultaneously with the wireless direction finder without causing interference, and the projector, which is only about 1ft. in diameter, never requires adjustment. Echometer sounding devices are shown at the Exhibition with ranges of 720, 360, 160, 90, and 30 fathoms.

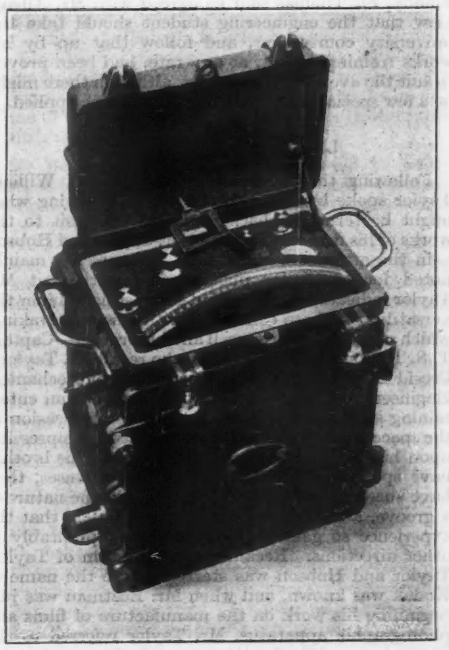

Fig. 52—"Echometer" Sounding Device—Marconi

The deep sea instrument, reading up to 720 fathoms, is fitted in halibut-fishing craft and whaling vessels. When fishing halibut banks, such as those off the Greenland coast, the Echometer enables the skipper of a line boat to place his lines (often 12 miles long) at the exact depth at which experience has taught him the finest halibut will be found; while whaling fleets make use of the instrument in order to carry out their operations in the vicinity of the deep-sea banks where whales feed. With the standard Echometer provided with a 360-fathom scale, the trawl skipper is able to trawl on the edge of a bank with ease and precision, and to discover those hollows and depressions in the sea bed where the most sought after fish are known to congregate.

With a standard Echometer fitted with a 160-fathom scale, the navigator of a full-powered sea-going passenger ship proceeding at full speed has only to press a button and glance at the instrument to ascertain the true depth under the keel and the nature of the sea bottom. Thus he is enabled to navigate by chart position with ease and confidence under conditions of low visibility, and is relieved of much mental strain when bringing a ship into port in unfavourable weather.

For coastwise shipping and smaller fishing craft there is a 90-fathom Echometer, which, in addition to giving depths under the keel and locating in terms of direction and distance objects on the sea bed, such as rocks, reefs, and wrecks, also indicates by mid-water echoes, the presence of shoals of fish.

The smallest instrument made is designed for rapid and accurate surveys of shallow waters, such as harbours, rivers, estuaries, and canals.

(To be continued.)

An industry with a capital of some £500,000 is being organised in Saghalien, by Japanese interests, for the canning of sardines.

The British Association.

No. I.

Before giving his Presidential Address to Section G (Engineering) on Thursday morning, September 7th, Mr. R. W. Allen paid a tribute to the Recorder of the Section (Mr. J. S. Wilson) for the interesting programme he had prepared for the Section during the meeting, despite many disappointments.

We gave extracts from Mr. Allen's address on page 236 of our last issue.

The vote of thanks to the President was moved by Sir Thomas Hudson-Beare, who said that two outstanding points arose from the address. The first was that engineers should not neglect the history of their profession. At the present time too much attention was paid to the doings of the politician, the soldier and the sailor, and too little to the doings of the engineer, who had transformed civilisation. The second was the reference to the oil engine and its extraordinary adaptability. His great regret, said Sir Thomas, was that the oil necessary for the internal combustion engine is not yet available in our own country. Fortunately, there was good reason to believe that the problem of obtaining oil from coal had been solved technically, and it was now only a question of making it an economic proposition. Finally, Sir Thomas said he agreed with Mr. Allen's view that the engineering student should take the university course first, and follow that up by his works training. That, at any rate, had been proved to suit the average student best, although there might be a few special cases in which the converse applied.

Lenses and Golf Balls.

Following the Presidential Address, Mr. William Taylor spoke briefly with the object of giving what might be termed a background to the visit to the works of his firm—Messrs. Taylor, Taylor and Hobson—in the afternoon. This firm, of course, is mainly noted for lenses for photographic work, but Mr. Taylor indicated in a brief but interesting manner the versatility of those connected with this undertaking, which was started by himself and his brother—Captain T. S. Taylor—in 1887. Those who recall Mr. Taylor's Presidential Address to the Institution of Mechanical Engineers last session will appreciate what an entertaining speaker he is, and on the present occasion in the space of a few minutes he succeeded in impressing upon his audience that, although he and his brother have specialised in the manufacture of lenses, they have succeeded in avoiding anything in the nature of a groove, and that their minds are so alert that the experience so gained has been turned profitably in other directions. Recalling that the firm of Taylor, Taylor and Hobson was started before the name of Kodak was known, and when Mr. Eastman was just beginning his work on the manufacture of films and photographic apparatus, Mr. Taylor referred to the original aim of the brothers to make lenses on something like an interchangeable basis at a time when skilled craftsmen were able to make lenses by hand with an accuracy within one or two wave lengths of light. Paying a tribute to what he had learned in America, Mr. Taylor said his firm now makes some 240 different sizes and kinds of lenses, which require the stocking of 2500 different components, all of which are made interchangeable. Among these are the screws which are commonly used for attaching the elements in the lenses, and for which up to the present no better method has been found, despite its awful imperfections. As a result, methods of generating and gauging screws have been developed which he claimed to be the origin of almost all that is known to-day in the metrology of screw threads. There are also manufactured at the Leicester works of the firm a heterogeneous collection of products which have been forced upon the firm in the processes of lens making, because they could not be obtained outside. For instance, there is the engraving machine for doing work previously done by hand by men "who were not always available on a Monday morning," and at considerable expense. The engraving machine turned out by the firm was the first commercial proposition of its kind—although engraving of the same nature was previously done by Cooke's the lens makers—and many thousands of Taylors' machines are now in use all over the world. Another detail is the pantograph developed by the firm, and now used largely for the marking of cutlery, replacing acid engraving. This consists of a small electrode, vibrating at about 100 times per second, striking and re-making a small arc about the point of the pantograph, automatic means being provided to take care of the wearing away of the electrode and to maintain contact. Again, there has been developed a form of tubular cutter for lens blanks which has been applied to such purposes as the cutting of circular glasses for ships' porthole windows. Finally, Mr. Taylor, again paying a tribute to what he has learned from America, referred to the modern golf ball, and told how, as the result of taking up golf in America, he noticed that the embossed markings on the early types of ball led to fracture, with the result that his firm devised the first means for moulding gutta-percha-covered rubber balls with recessed marking, which machines are now used in many parts of the world.

Knitting.

The remainder of the morning of Thursday, September 7th, in Section G was taken up by a paper by Mr. John Chamberlain on "The Mechanisation of Knitting." It was pointed out that historians have undoubted proof that the art of weaving was practised by the Chinese in 3000 b.c., but the earliest date assigned to the production of knitting is the fifth century a.d. The first knitting machine was invented by the Rev. William Lee, of Calverton, Notts., in 1589. Whilst a triumph of mechanical ingenuity, it was of necessity crude and many scientific developments were required. Many types of machines were introduced in the nineteenth century, but, unfortunately, although the primary inventions were of British origin, many of them were developed in other countries. Germany built flat machines and warp knitting machines, and later the Cotton's machine. France built the sinker wheel machine; Switzerland built flat machines; and the United States built plain seamless hose machines. Although Great Britain made a large variety of machines, it was not until 1914 that attempts at mass production on a large scale were undertaken. Operations were interrupted by the war, but renewed efforts were made in 1918 and since then a great deal of progress has been made. Certain types of machines are built in Leicester—one type exclusively—and exported all over the world, but, on the other hand, many kinds of machines are imported, so that even to-day Great Britain does not produce her quota of knitting machines for the world's markets, and uses only an infinitesimal quantity of British-made needles.

The paper contains a detailed account of the operations carried out by various types of machines, and stress is laid on the fact that mechanisation of knitting has proceeded to such an extent that the number of loops that a single operator can now produce by the aid of machinery is over 3,000,000, whereas by hand the number is less than 300, per hour—a tenfold increase. This would have been impossible, however, but for the development of highly accurate machine tools, such as milling machines, trick-cutting machines, grinding machines, &c. Whilst this is an excellent example, showing how applied science assists the smaller industries, it is pointed out that the amount of research of a commercial character in the knitting industry has been exceedingly limited. The author suggests that this is probably due to the fact that at present it is more remunerative to invent than to research. As hundreds of patents are taken out yearly, however, and as many British builders spend thousands of pounds sterling on experimenting, further mechanisation of knitting is likely. Nevertheless, at present the method is inevitably that of "trial and error." Few machines have even a revolution counter, none have tension meters, adjustments for knitting various yarns are quite arbitrary, and no one knows the relationship between stitches per unit of length of yarn and courses per length of fabric. No one expects to get uniform weight per length, and hose of uniform length is unknown.

The President, opening the discussion on the paper, said that those who had hitherto been only familiar with the products of knitting machinery would have been impressed by the ingenuity of the machines, as described and illustrated by the author.

Mr. Percy Bentley remarked that some years ago he came into this industry as an engineer, knowing nothing about it, but with the help of the author and men like Professor Hele-Shaw, it had been possible to develop the knitting industry from an engineering point of view, to such a state of perfection that machines could be reproduced which could be sold with a guarantee of performance.

Mr. J. S. Wilson (Recorder, Section G) referred to the standardisation of product and commented on the author's reference to "trial and error" results.

Mr. Chamberlain replied that these difficulties were introduced by the varying character of the yarn used, adding that there was a much greater variation in those raw materials than there was in engineering raw materials. Difficulties were also introduced through changes of fashion and the attempt so often made to use the same machines, without modification, on cotton, artificial silk, or wool.

Motion Study.

In Section J (Psychology), on Thursday, September 7th, Miss A. G. Shaw (chief supervisor of women and motion study investigator of Metropolitan-Vickers) gave an address on "Motion Study Applied to Small Assembly and Machine Work." The study is concerned with the assembly of small electrical meters and instruments, and most of the operators are girls of approximately twenty-three years of age who have been on the work for several years.

The aim of motion study investigation therefore is to examine the job from the point of view of the individual who is doing it, and to consider his movements on the job. To do this it is essential to get a complete picture of the operation, to apply the knowledge of movements in respect of the tools and materials which are used, and to consider whether it is possible to supplement and increase the scope of the operator's abilities by the use of additional tools and machines. The need is to have some means of measuring the operation from the above point of view, and to decide to what extent such methods are justified. The methods of measuring devised, developed, and used by Lilian M. and Frank G. Gilbreth in America are employed. They are three in number:—

(1) Process charting, giving the picture of a job as a whole.

(2) Micromotion photography, measuring the nature and type of the movements.

(3) Chronocyclegraph study, from which it is possible to analyse the path of the movement.

By process charting the process is shown up in an entirely new light and every deviation from the standard practice becomes obvious, and stages come to light which are not at all apparent in the work itself or in a written description of it. In micromotion photography, the operator's actual movements are the centre of attention. Motion pictures are taken of the operation under investigation with a clock in the field of view. Once the film has been exposed and processed, it is projected and analysed, and one of the first things is to show it to the actual operator involved, and any others who particularly wish to see it. A special point has been made of this, as it is felt that it increases the understanding and co-operation. The picture is analysed in every detail, and once an improved method has been completed, as a result of this analysis, an operator has to be trained to do the job, and another to act as substitute. There is now a special training section where each operation is brought for investigation and where the operators are taught. The operator is brought into the section and assured at the beginning that she will get a flat rate of the same average amount that she had been making on piecework for the last ten weeks. This means that from the outset she is not worried with the thought of losing money when stopped or corrected. Then the investigator demonstrates the movements, and allows the operator to start while he watches her very carefully and corrects all wrong movements.

The results of such investigations naturally vary, but the average increase in the daily production per operator of all investigations carried out in the three years the section has been in existence is over 100 per cent. This does not mean the speeding up or driving of the operators, but is due to simplification and elimination of all unnecessary movements. Such results might suggest that the work would become more monotonous, but experience has shown that the reverse is true; operators take more interest in the work than before. One fact proving this is the increase in the number of profitable suggestions made by the operators who have been motion-study trained.

Salesmanship and Prices.

Dr. E. F. Armstrong, speaking in a discussion in Section F (Department of Industrial Co-operation) on Thursday, September 7th, dealing with "Organisation as a Technical Problem," mentioned that a meeting of the Sixth International Congress for Scientific Management, will be held in London in the week beginning July 15th, 1935, under the Presidency of Sir George Beharrell, and that His Royal Highness the Prince of Wales had kindly consented to act as Honorary President of the Congress. Among the general questions to be discussed are (1) the position of scientific management in small or medium-sized works with particular reference to the part associations can play in its promotion; (2) budgetary control of production forecasting; (3) questions affecting distribution, in manufacturing, wholesaling, and retailing; (4) training, with particular reference to the supply of men for the larger commercial undertakings and public administration, and (5) agriculture, the part standardisation of plant products, &c., can play in agricultural economics.

Continuing, Dr. Armstrong expressed the opinion that there was an opportunity for the application of scientific method to salesmanship. In the works during the last decade or more, science had effected many changes for the better, and it would be true to say of not a few industries that their technical efficiency was near a maximum and that it would not be very much increased in the near future, or, at any rate, that those industries had more pressing problems to solve in other directions. There were, of course, some other industries in which there was still great scope for technical progress, and new industries would constantly arise for development. In the main, however, it was on the selling side that there was most to be done. Modern salesmanship had, to some extent, been satisfied by graphs showing an increasing volume of sales accompanied by an increase of overhead costs, though the burden of these per unit sale had been diminished. The corresponding profit and loss curve, however, had often been lost sight of by the salesman; it should be shown on the same graph, for it was the final arbiter of success.

Competition had become so very keen in domestic markets, and still more so in export markets, that the salesman and those at the head of affairs had found it necessary continually to lower prices in order to effect any sales so as to keep the works going. The repercussion of that had been felt by every competitor and its effect was cumulative. It might at least be suggested that in the long run the orders were divided among the chief competitors, and that the same division might have been effected at considerably higher and, therefore, more remunerative prices, had common sense prevailed at the outset and the competitors found it possible to come to some agreement on a quota basis. The attempt seemed to be well worth making; that the task was a difficult one it would be futile to deny, but it was so necessary that industry should be carried on at a profit, and that the limited work available should be shared, that no selfish consideration should be allowed to dominate what had now become world problems. All salesmen and most buyers would welcome controlled prices. The actual price often did not matter so much to a buyer as the fact that a competitor might buy at a lower price.

It was bad policy for the industrial nations to undersell one another to an extent which amounted to a subsidy of the smaller nations which thereby might be placed in a position that they, in turn, were able to engage in manufacture and enter into the whirl of competition and so depress prices still further. He believed there was definite scope for the treatment by scientific methods of these problems.

There was a very full programme in Section G (Engineering) on Friday, September 8th, the greater part being devoted to a general discussion on "The Film in Engineering." Before that was taken, however, Mr. S. Capon read a paper on "The Reduction of Aircraft Noise." Last year, before Section G, Dr. Kaye gave an account of the steps that were being taken to reduce aircraft noise, and in the present paper the author, who is connected with the Royal Aircraft Establishment and has been carrying out researches at the National Physical Laboratory, described the further experimental work in progress at the N.P.L., the Royal Aircraft Establishment, and the Air Defence Experimental Establishment directed to this end. Attention was focussed primarily on the reduction of the noise heard by the occupants of the aircraft. This carries with it some diminution of the noise heard on the ground, although the improvement has not necessarily been the same.

NOISE IN AIRCRAFT.

A marked improvement has already been obtained in our air liners mainly by sound-proofing the cabin walls, and it is claimed that the noise in the cabin which originally compared unfavourably with that of a pneumatic drill at close quarters has, in some instances, been reduced to about that in a train with open windows. Nevertheless, the author does not think the position can be accepted as satisfactory until a marked reduction in the noise emitted by the two chief sources, the air-screw and the engine, has been obtained. At the same time, it is recognised that while the engine and the air-screw are the chief sources of noise, there are others which may require consideration later on, but which are masked at present by louder noises.

So far as the airscrew is concerned, it has been shown that the noise depends primarily on the speed of the tips of the blades, and that lower tip speeds are required for quietness. The improvement obtainable in this way, however, is limited by the engine exhaust noise, which is about 80 decibels in cruising flight. Effective exhaust silencers of the baffle type can be made, but they may involve some increase of fire risk in the event of accident. It is estimated that the noise level in a single-engined aircraft might be reduced to rather less than 70 decibels—approximately that in a train with open windows—by the use of an exhaust silencer and low-speed airscrew, say, 650ft. per second. An airscrew tip speed of 600ft. per second would give an estimated general noise level of 66 decibels if none of the secondary sources of noise—engine clatter, noise due to the vibration of structures, or to air flow over wires, &c.—emerged. The improvement in quietness at the ground due to reduction of tip speed and the use of exhaust silencers, however, awaits investigation.

The paper attempts to link together and interpret the experimental results which have been obtained up to the present, but it is admitted that some of the conclusions are based on experimental evidence which is not strong. In particular, further investigation of the discrepancy between the observations of airscrew noise at zero forward speed and in flight is regarded as being required as well as measurements of exhaust noise under cruising conditions. It is even contemplated that some of the conclusions already drawn will be modified by further experiments. The paper describes in considerable detail measurements made with the Siemens Barkhausen audiometer of aircraft noises in flight and of the noise of airscrews and engines on the ground, various deductions being made as to the means by which the noise may be reduced.

The President (Mr. R. W. Allen) said it was a satisfaction to know that such researches as those described in the paper were being carried on, because they would certainly tend to make life more bearable. Somewhat grimly remarking that the real solution of the noise problem from the point of view of the human being was death, he recalled that in the Navy similar troubles had been experienced, and quoted an instance in which the noise from a destroyer was heard 10 miles away.

Mr. H. E. Wimperis, after expressing his appreciation of the wonderful researches that are being carried out in this connection by Mr. Capon, under the guidance of the Royal Aircraft Establishment, and by Dr. Tucker for the War Office, said the most remarkable result achieved so far in aircraft was the passing of the cotton-wool era in civil aviation, for it was only a short while ago that all passengers had to use cotton wool in their ears to lessen the effect of the noise. On the new Handley Page machines, however, that was no longer necessary. Moreover, the enormous and continued growth of the traffic carried by Imperial Airways was due in a very large measure to the success of the work of Mr. Capon and Dr. Tucker. An important application of this work also was in rendering the cabins of the wireless operators on Army aeroplanes and naval seaplanes less noisy, a serious problem hitherto. Speaking of the emphatic desire of the public that aircraft noises should be reduced, Mr. Wimperis said it was amazing that, whilst that opinion was generally held, the public continued to tolerate, without protest, the awful noises from pneumatic drills, motor horns, &c., which were such a common feature of every-day life on the ground. Personally, he did not see why the relatively harmless noise from aeroplanes should be singled out for attack by the public. If the public protested, in regard to pneumatic drills, &c., as vehemently as it had done with regard to aircraft, that it wanted something done, perhaps there would be an abatement of those nuisances. Whilst steps were being taken to deal with aircraft noises, nothing was being done in the other directions to which he had alluded.

Dr. W. S. Tucker said that whilst the Barkhausen instrument had done wonderful work, we really still had no more accurate method of measuring noise than the human ear. With the Barkhausen instrument it was possible to have an error of as much as 6 decibels, which meant that one could not distinguish between one noise and another which was four times as loud. In cases where measurements had been taken as close as 10ft. or 12ft. from the ground, the noise was so great as to be positively painful to the ear, whilst in the air the effect of extraneous noises due to engine clatter, &c., was such that the human ear was quite incapable of giving logical results, even when the sound was reduced by 10, 15, or 20 decibels. Another difficulty when measuring noise from aircraft in flight was that the sound was directed by the motion of the machine, so that the noise was greater when measured in one direction than when measured in another. For that reason it was very difficult to assess whether the silencing of an aeroplane had been successful or not.

Dr. Miller, speaking on the medical aspect of noise, expressed the view that the noise from aircraft in flight was not so injurious to human beings as other noises on the ground which were intermittent. The continual noise from aircraft soon ceased to stimulate; indeed, many people regarded it as a musical note which was not in any sense objectionable. In addition to the other noises on the ground mentioned by Mr. Wimperis, there were the fearful and sudden snorts from locomotives at railway termini, and also the sudden piercing blasts on the whistles of locomotives, both of which seemed to him quite unnecessary and far more objectionable and injurious than any noise from aircraft.

Sir Henry Fowler asked what had happened in regard to the resolution passed by Section G at last year's meeting, calling upon the Home Office to take steps with regard to noise on the ground, more particularly with regard to motor bicycles.

Mr. J. S. Wilson (Recorder, Section G), said the resolution was sent forward by the General Committee to the Ministry of Transport and the Board of Trade, and was formally acknowledged, but so far as he was aware nothing had been done. It might therefore be useful to endorse that resolution on the present occasion and again put it before the General Committee.

Speaking on the paper, Mr. Wilson said it was a serious matter to be told that the only real method of measuring noise at the present time was the human ear, because if it were desired to fine people for making undue noise, there must be some scientifically accurate method of measuring it. It was therefore to be hoped that a method would soon be devised.

Wing Commander T. R. Cave-Brown-Cave suggested the importance of calling attention to the manner in which the principles arrived at as the result of those experiments could be applied to general problems. In the case of the motor bicycle, he believed it was absolutely true that a resonable form of silencer could be fitted, which would reduce the noise to a quite inoffensive one, but at the same time would not reduce the power to an extent that could be noticed by any driver. It would have been interesting if the author had indicated the extent to which the power of aircraft engines was reduced by the fitting of silencers or the reduction of airscrew tip speeds. Incidentally, he recalled some German experiments in which the adoption of slow rotating airscrews revealed the noise from the gear to be the dominant one. How would the large geared airscrew suggested by the author affect that aspect? On one occasion when at Farnborough he had suggested using an exhaust pipe perforated over a considerable length, and a considerable degree of silence was produced in that way. Could the author say whether that would give a reduction comparable with the 37 decibels now considered the optimum.

Dr. S. J. Davies (Joint Secretary, Section G), said that the Sunbeam Company had shown that it was possible to produce a silent-running motor cycle without seriously impairing the power. Speaking on the aerodynamic side, he asked for information as to the relation of the variation of the Reynolds number to the production and transmission of noise from the tips of the propeller blades. He also asked whether any allowance had been made in the tests of engines on the test bed for reflected noise in the engine-house, as compared with the conditions in the air.

Mr. Capon, replying to the discussion, said he believed that with an airscrew tip speed of 650ft. per second, a good take-off would be obtained, and the power in the air would not be less. There would be a considerable reduction of noise in that event. As to Dr. Davies' remarks on the conditions in the test house, allowance had been made for them in the results given in the paper, although it was not easy to make.

Dr. Davies, at the request of the President, read the text of the resolution concerning noise passed last year, as follows:—

> "That the British Association calls the attention of the Home Office to the objectionable and largely preventible noises caused by motor vehicles, and suggests that the Home Office should make greater use of the powers that they possess for dealing with such nuisances."

Sir Henry Fowler suggested it should be added that, so far as motor bicycles are concerned, a diminution in noise does not mean any practical diminution in power.

Wing-Commander Cave-Brown-Cave thought it would be narrowing the basis of the resolution by mentioning one example and suggested that attention should be drawn to the fact that in regard to aircraft certain principles for the reduction of noise had been evolved, and if those general principles could be laid down in a form in which they would be applicable to general problems, much more effective action could be taken by the Association.

Eventually it was agreed to refer the matter to the Committee of the Section, which was asked to draw up a suitable resolution.

THE FILM IN ENGINEERING.

The Section then discussed the question of "The Film in Engineering." This was opened by Mr. H. E. Wimperis, of the Air Ministry, who showed films indicating the manner in which films are being applied to aeronautical research. He pointed out that the film may be used in three quite different ways in engineering research. The simplest use was to record the rapidly changing indications on the dials of instruments in cases where it was impossible to have an observer, or where, if there was one, he could not make and record his observations quickly enough. An example was the "automatic observer," used in the testing of single-seater aircraft. Another use lay in the ability of the cinema camera to make, at any desired speed, a record of the position or altitude of some moving body, the films being afterwards measured up under a microscope. An example was found in the study of the motion of the spin of a free flying model, whilst another was the study of the full-scale motion of porpoising in a flying boat. The third method of using the film was to take slow-motion pictures of rapid movements so that they could be easily followed by the eye, thus enabling the quality of the action to be studied or demonstrated, *e.g.*, the study of the launching of an airplane from a catapult.

A number of films illustrating these uses of the cinema camera were shown. Among the points indicated by these films was the precise action of the Handley Page slot in preventing stalling; the manner in which the undercarriage takes the shock of landing, and the manner in which new landing devices have been evolved to meet the higher landing speeds which tend to follow higher flying speeds, such as the Oleo dashpot arrangement, and so on. It was explained that no new type of Army aeroplane is allowed to be put into construction until it has passed through, in the model stage, a series of tests, all of which were indicated on the film.

Sir Henry Fowler followed with a film and a brief description of the oversea motor unit designed for transport in the Dominions and Colonies where road conditions outside the town are not of the best, which was fully described and illustrated in our issue of July 21st, 1933.

"The Testing of Electrical Switch Equipment" was the subject of the next film, which was exhibited by Mr. W. Wilson. Mr. Wilson expressed the view that the cinema camera and similar recording cameras were of the greatest use in connection with the testing of electrical equipment and were destined to play an increasingly important part in such work.

Their principal uses were said to be, first, the recording of the visual results of tests, more especially those effects which might be too transient for reliable detection by the eye, and secondly, the keeping of a continuous and simultaneous record of the readings of a comparatively large number of meters during a long cycle test. Tests belonging to the first category were exemplified as those on electrical circuit-breaking apparatus, such as large oil-immersed breakers, high-speed air circuit breakers, fusible cut-outs, and lightning arresters. In all these, the significant part of the test lasted only a short time, such as from one cycle to seven cycles (20 milli-seconds to 140 milli-seconds), and a complete record could, therefore, be afforded by only a few feet of film. The data supplied by the photographic record included the nature and duration of the arc—in the case of an air-break apparatus—the emission of flame, smoke, or molten metal, the duration and speed of any visible effects and, not least important, the moving or springing of the various parts. Such records were especially valuable in that they were not only able to detect such occurrences, but also to measure with a close degree of accuracy their dimensions and duration.

Illustrations of such records were exhibited. One example was from a film recording a dead short circuit to earth at a grid sub-station, and was actually taken out of doors while the blizzard of February 24th last was at its height. The arc was struck between a pair of horns by bridging them with a fuse wire prior to the closing of the main breaker. Besides showing the successive shapes assumed by the arc while it was extending, the film also indicated the relative intensity at the various stages, and its duration. The total length of the arc in that case was from 14ft. to 20ft., and extinction was brought about by the opening of the circuit breaker.

Since the duration was short, and the luminosity was intense, most arcing tests could be very conveniently recorded by means of a simplified form of motion-picture camera, which rendered high speeds practicable, and required only a single glass plate of, say, half-plate or whole-plate size. Such a camera had, the author said, been designed in the laboratory of the firm with which he was associated, and consisted of twelve similar lenses, each of which produced a separate image and was uncapped in turn by means of a simple rotary disc shutter driven by an electric motor. Field and armature regulation of the latter varied the speed of the shutter over a wide range. For instance, twenty-four to one hundred pictures might be taken per second, the speed being capable of exact measurement. Examples of the records thus obtained were illustrated. Tests with that camera showed that the extinction of a direct current arc was complete in one-third of a second, whilst an alternating-current arc took only one-sixteenth of a second. Attention was called to an interesting feature in connection with the rupture of an arc arising out of these tests. The common theory was that it snaps at one point, very much like a stretched thread, and quite wrong conclusions have been based on that assumption. The photographs proved that this was not the case, but that the arc persisted until there was not sufficient electrical input to maintain its temperature and consequent ionisation, whereupon it faded away uniformly over its whole length.

One of the great advantages of photographic recording, said Mr. Wilson, was its ability to give a comprehensive and definitely correlated account of the behaviour of all the pieces of apparatus concerned in a test, enabling cause and effect to be seen together. An instance was illustrated where the protection of rotary converters by a high-speed circuit breaker was analysed. In order to obviate the highly destructive effects resulting from the flashovers to which traction machines are subject, the air circuit breaker must be able to open its contacts and break the circuit in 0·1 second or less. After both rotaries had been short-circuited, and were beginning to flashover, the film showed that the high-speed breaker had already begun to function. Before 0·38 second had elapsed the flashover was extinguished, and the circuit broken. The concluding portion of the film explained a curious apparent prolongation of that particular arc at the commutator of one of the machines, a phenomenon now seen to be due to a transient recrudescence of the flashover through a species of alternating-current surge taking place while the circuit was actually broken.

Finally, an example of the second type of test film mentioned was shown, viz., the simultaneous recording by the cinema of numerous quantities during a test cycle. It related to an assembly of no less than seventeen instruments employed during the sea trials of the 19,000-ton electrically propelled quadruple-screw liner "Queen of Bermuda." The ship was put through a specified series of manœuvres, including starting, varying speed, and sudden reversal, and the various meters indicated the time, helm position, reading of the ship's log, voltage, excitation, and speed of each of the two alternators, and the armature current and speed of each of the four motors driving the propellers. A study of the successive readings was found to be of the greatest value in determining the transient effects at the various points of the cycle.

To conclude this discussion and exhibition of film, Mr. Alec Rodger, of the National Institute of Industrial Psychology, showed a film illustrative of some of the applications of the cinematograph film to that side of engineering which deals with the selection of operatives.

The President, in bringing the meeting to a close, and thanking all who had taken part in the proceedings, suggested that any doubts that might have existed as to the value of the use of the cinematograph film for engineering and industrial purposes generally must have been removed by what had been seen that morning. He recalled that when in 1929 he went to Tokyo as a British delegate to the World Power Congress, he thought it might stimulate manufacturers here if he took a film depicting certain directions in which trade might be developed and extended in Japan, and added that that film had been in great demand in this country on many occasions since. Another example was the film which had been taken by Sir Henry Fowler of all the stages of the building of his wonderful "Royal Scot" locomotive when he was at Derby.

(To be continued.)

Obituary.

SIR GILBERT VYLE.

SIR GILBERT VYLE, whose death, after a long illness, will be deeply deplored, was an engineer who, by force of circumstances or taste, had given up the technological side of his vocation and devoted himself principally to economic questions. We have two or three living examples of such men, and it is difficult to over-rate their value. Being able to speak to engineers as one of themselves, and being also in close touch with engineering industries, their words are listened to with a degree of attention greater than that usually accorded to abstract economists, and their advice is sought and respected. A mere list of Sir Gilbert Vyle's engagements shows the nature of his interests. He was a member of the Royal Commission on Decimal Coinage, of the Water Power Resources Committee, of the Safeguarding Inquiry Panel, of the Special Inquiry into Fabric Gloves, of the Departmental Inquiry into the British Industries Fair, of Lord Chelmsford's Committee on the British Industries Fair, and of the Inquiry into the Exports Credit System. At Geneva he was the Government adviser on imports and exports restrictions, and was trade adviser to the British Government Delegation at the Ottawa Conference. In 1923 he was President of the Birmingham Chamber of Commerce; in 1926–1927 President of the Association of British Chambers of Commerce; and in 1929–1930 President of the British Engineers' Association. He was also at one time Vice-president of the Engineering and National Employers' Federation, and Chairman of the British Committee on Empire Trade; and he had been a member of the Development Council, Department of Overseas Trade, and of the executive Committee of the Travel Association of Great Britain and Ireland.

The Engineer

SIR GILBERT VYLE

In all his undertakings, as adumbrated by the list we have just given, he shone as an imperialist. In him there was no "craven fear of being great." He believed stoutly in the British Empire and desired to see it knit ever more closely together. In his speeches—he was an exceptionally clear and effective speaker—he often urged the need of permanent machinery for regular consultations between the various parts of the Empire. "We require," he said, in a speech which may be regarded as typical, "a permanent establishment, a Ministry, if you like, of all the Ministries of the Empire, devoted solely to the work of developing the trade of the Empire. It must have powers to investigate and to advise as to the policies which will give us what is needed in order to develop inter-Imperial trade." Having great knowledge of the needs of industry at home and in the Dominions, he was able to enforce his opinions by sound and effective argument.

Sir Gilbert was only sixty-three at the time of his death on September 7th. He was the son of Mr. Samuel Vyle, of Haverfordwest, in Pembrokeshire, who was one of the pioneers of electricity supply, and it was natural that he should have been trained as an electrical engineer. As a young man he entered the engineering branch of the Post Office, but a few years later went abroad in the service of the Colonial Office. On his return he took up the manufacture of electrical apparatus, but surrendered it when he had developed a practice as a consulting industrial engineer in Manchester. Subsequently, he joined the Board of W. and T. Avery, Ltd., of Birmingham, and became managing director. During the war he was engaged on the organisation of aircraft supply, and the production of other war material, and he was Chairman of the Finance Sub-Committee of the Ministry of Munitions.

In recognition of his many public services, he was knighted in 1928, and was this year created a K.B.E. He will be missed particularly by the members of the British Engineers' Association, for his was a very familiar figure at the Association luncheons, and his attitude towards the engineering industries was exactly suited to the inclination and interests of the members.

Letters to the Editor.

(We do not hold ourselves responsible for the opinions of our correspondents.)

"MONEY v. MAN."

SIR,—May I congratulate you on your leading article drawing attention to the Presidential Address of Sir Frederick Gowland Hopkins to the British Association on September 6th, and more particularly for singling out his remarks on the present dangers of "Money *versus* Man"?

That this is a pressing danger to-day may be seen in the fact of starvation in the midst of plenty to which you allude, a situation which obviously arises from the inability of those who are starving to secure the money necessary to enable them to satisfy their needs.

The operators of the money system have arrogated to themselves for too long the position of dictators of morals by maintaining their doctrine of scarcity and the Pauline injunction of "work or starve" in an age of actual and much greater potential plenty. This injunction was justifiable at the time of its pronouncement, and doubtless for many years afterwards, but its enforcement to-day is a crime, the heinousness of which is indicated by the ever-rising number of suicides in every industrialised country, including our own.

To-day, labour—*i.e.*, work for mere sustenance—becomes decreasingly necessary as a result of the application of solar energy to the problems of production; but while work remains man's only claim to a share in the abundance thus created, the discoveries and inventions of the scientist and engineer must be a curse instead of a blessing.

Because, both in this country and the United States, this question is being approached as a problem of providing work instead of one of distribution, and man's claim to a share of the benefits accruing from the labours of the past—a truly communal cultural inheritance—is ignored, no trade revival in either country can be permanent, and the greater such a revival appears, the greater must be the subsequent slump.

All technicians should take warning from the recent acts of sabotage resulting from financial dictation, the destruction of unsaleable, though not unwanted surpluses, and so-called redundant plant, for, if they do not unite for resistance, they may yet find such activities as the discovery and invention of improved productive processes indicted as criminal offences against the community.

M. JACKLIN.

West Clandon, Surrey, September 12th.

AGRICULTURAL MACHINERY TESTING COMMITTEE.—A revised edition of the explanatory pamphlet describing the scheme of the Ministry of Agriculture and Fisheries for the testing of agricultural machinery and implements has just been issued. Certain changes have recently been made in this scheme with the object of making it of more service to the interests concerned. As in the past, a certificate and report on each test will be issued. The certificate will be in a more concise form than formerly; it will state the bare facts of the test, and will be suitable for reprinting in a catalogue or other literature. The report, in addition to giving the details of the test and the results obtained, may contain expressions of opinion with regard to the design and performance of the machine. Both certificate and report will be published by the Ministry in one pamphlet, and either or both may be reprinted by the applicant for his own use. Copies of the pamphlet may be obtained free of charge from the Secretary, Ministry of Agriculture and Fisheries, 10, Whitehall-place, London, S.W.1.

Railway and Road Matters.

At Leicester siding accommodation, which will permit wagons containing an additional 180 tons of traffic to be dealt with at one time, is to be laid down in the L.M.S. goods shed, together with improved cranage and traverser facilities.

A new "halt," known as Gelli Felen, situated between Brynmawr and Clydach stations on the L.M.S. Railway's Abergavenny-Merthyr line, was opened for traffic on September 6th. It will provide railway facilities for several villages in the Llanelly Hill district.

Four wagons, left standing on the up main line at Bowling on the Glasgow and Helensburgh section of the London and North-Eastern Railway, were, on the morning of Friday, September 8th, run into by an express at high speed. There were, however, no cases of personal injury.

The present President of the Trades Union Congress, Mr. A. G. Walkden, is a former railway servant. He was a clerk on the Great Northern Railway, but left railway service in 1900 to become the general secretary of the Railway Clerks' Association, for which and for the railway companies he has done good work in a quiet, unostentatious way.

The new docks and marine manager, Southern Railway, in place of Mr. G. R. Wencombe, who has retired owing to ill-health, is Mr. E. J. Missenden, who has been the assistant superintendent of operation in the traffic department. Mr. R. P. Biddle, who was the assistant marine manager, has been given the rank of assistant docks and marine manager.

We are informed by Sir W. G. Armstrong Whitworth and Co. (Engineers), Ltd., that reports have recently appeared in the Press to the effect that their new 800 H.P. Diesel-electric locomotive is capable of hauling a load of only 250 passengers. This, they say, is a considerable understatement of its capabilities, since the locomotive can haul from six to eight ordinary passenger coaches.

As is generally known, the railway companies, mainly because some leaders of the men announced beforehand that they would not accept the award of the National Wages Board last December on a question then still under consideration, gave twelve months' notice in January of their withdrawal from the Central and National Wages Boards. They, at the same time, intimated that they would be prepared to consider the adoption of some more suitable procedure. It is now announced that the companies have approached the three railway unions as to a meeting shortly to discuss the question.

So much attention has been paid to the valuable national services rendered by the late Viscount Grey, that the fact may escape notice that he was closely identified with the North-Eastern Railway and its successor, the London and North-Eastern. He joined the board of the former company in 1899 and became its chairman in 1904, but resigned his directorship when he joined the Campbell-Bannerman Government in December, 1905. His retirement from the position of Secretary of State for Foreign Affairs, after holding that office continuously for eleven years, permitted his return in 1917 to the North-Eastern Board, and he remained a director when the L. and N.E. was formed.

The fusion of the Metropolitan Railway, along with the Metropolitan District and the tube railways, into the London Passenger Transport Board, is, it is announced, about to lead to the removal of an inconvenience experienced by passengers journeying between the District line and the Uxbridge branch of the Metropolitan. The latter, besides being between Harrow and Uxbridge, has a branch from Rayners-lane, which was opened on March 1st, 1910, and makes an end-on connection with the District Railway at South Harrow. The inconvenience mentioned above is that passengers have to change trains, and generally platforms also. That is shortly to be removed by through District and tube trains to and from Uxbridge.

The Bishops-road Station of what, for convenience, we will refer to as the Metropolitan Railway ceased to exist as a separate entity on Monday last, September 11th, having been merged into the Paddington Station of the Great Western. The City Railway Company was formed in 1852, and in the following year the North Metropolitan Railway was sanctioned, which name was changed to the Metropolitan Railway Company in 1854. Under the Act of the latter year, the railway was to start opposite the Great Western Hotel, *i.e.*, in Praed-street, and there was to be a junction with the Great Western at Bishops-road. The line was opened on January 10th, 1863, and was worked with Great Western engines and coaches, for which purpose the railway was of mixed gauge, as the Great Western rolling stock was of the broad gauge. The Great Western still exercises its running powers for goods traffic, but the steam locomotives of the passenger trains are exchanged for electric at Bishops-road.

Although it was only as recently as May 19th last that we gave the assurance that no train accidents can result from a signalman dying or being taken ill at his post, we must again refer to that subject because of the remarks made on August 31st by the Manchester County coroner at the inquest on a signalman who, after having been found in a state of collapse in his signal-box, died in Manchester Infirmary. The coroner is reported to have said that should sudden death overtake an engine-driver it was possible that his fireman might avert a catastrophe, but if a signalman died while working alone in his cabin the consequences might be too awful to contemplate. That, we would repeat, is not so. No train is allowed to approach a signal-box without the permission of the signalman there. If that man is incapacitated he cannot give the permission, and his silence would lead to inquiry; if he was taken ill after permission had been given his failure to report the passage of the train would raise suspicion. In this particular case the man's signals were against a train, and its prolonged detention led to the fireman going to the box and finding the signalman ill. Further, all the time the train was detained no second train could follow it.

Notes and Memoranda.

For brass, drills are best made with straight instead of spiral flutes. A twist drill in brass is "greedy," while in deep holes the chips come off in such a way that they fuse into a solid mass in the flutes, and are difficult to get away.

It is, says the *Machine Tool Review*, considered standard practice to-day to finish automobile and aeroplane motor cylinder bores by honing with abrasive sticks. Automobile cylinders, for example, reamed to within 0·002in. or 0·003in. of size, are honed to an accuracy of 0·0005in. at the rate of 95 six or eight-cylinder blocks per hour on a multiple-spindle honing machine under the supervision of one operator and a helper.

Scientific circles in Cracow, states the *Chemical Trade Journal*, are keenly interested in a remarkable phenomenon which has occurred at Krynitsa, a Polish health resort close to the Czecho Slovak frontier. While work was proceeding on a new mineral water boring solidified carbon dioxide was brought to the surface from a depth of 2800ft., settled on the ground like a light covering of snow, and then quickly evaporated. It is claimed that this is the first time solidified carbon dioxide has appeared directly in nature. The solidification is ascribed to the terrific pressure which must exist in the subterranean regions from which the gas escaped.

The oil and mineral riches of Chinese Turkestan are described in the *English Review* by P. S. Nazdroff. The oil is worked to the west of Kashgar at a place called Kusheiku, near the city of Ak Su, and at Kucha. It is simply distilled for lamp oil and burns excellently in the native chiraks without any purification. Like the oil of Russian Turkestan, it has a high content of paraffin wax. At Kashgar, near Ming Yul, the oil contains a considerable proportion of benzine. At Kucha it is of a light yellow colour, precipitating on freezing an almost pure white paraffin wax. There can be no doubt that these deposits of oil will one day play a very important part in the life of Siberia and the Far East.

Of the seventy-five elevators in the new Rockefeller Centre Building in New York, twenty-four normally rated 3500 lb. at 1200 f.p.m. are, says the *Engineering News-Record*, of particular interest, as they are the highest speed passenger elevators in operation. Some of them have been operated at 1500 f.p.m., during performance tests, and one has been approved by the city inspectors to operate at 1400 f.p.m. These elevators are of the automatic landing type; they travel from 497ft. to 779ft., and some of them represent a total suspended load of about 25,530 lb. The highest-rise cars make a round trip with terminal stops only in 95 seconds. They will be in motion about 58 per cent. of the time, and for 40 per cent. of the time will be running at full speed. These duties and the long express runs involved require an elevator machine motor with a rating of 100 H.P.

Wawona Tunnel in America is 4233ft. long, absolutely straight, and is cut through solid granite the entire distance. It was constructed to make possible a road with a maximum gradient of 5 per cent. from Fresno and Los Angeles to the Yosemite Valley floor by way of the Wawona Big Trees. From the mouth of the tunnel magnificent Yosemite Valley bursts into full view, including such spots of scenic grandeur as snow-capped "Clouds Rest," the massive granite mountain "Half Dome," the sheer 3600ft. precipice of "El Capitan," and beautiful "Bridal Veil Falls." The tunnel proper consists of a 24ft. roadway and a 3ft. walk. To protect visitors from carbon monoxide gas detectors are installed, which automatically operate two 250 lb. General Electric thrustors to close the dampers, and three 150 lb. thrustors to open the fan shutters and start the fans. This operation is reversed when the air becomes purified. The fans are installed in a ventilation tunnel drilled to the face of the cliff from about the centre of the tunnel.

New York City is, says Mr. R. G. Albion, of Princetown University, essentially a product of the Communication Revolution. The Industrial Revolution may have been responsible for the growth of Manchester, Birmingham, and Pittsburgh. New York, on the other hand, first drew ahead of its rivals because of its foresightedness in digging a canal to draw grain from the West, establishing liners to draw manufactures from Europe, and utilising the steamboat to distribute its products along the coast. If new communication devices gave New York its start, they were absolutely necessary to handle its ever-increasing population. In 1800, it had about 72,000 inhabitants; in 1930, the municipal area contained nearly seven million, and the whole metropolitan area about eleven million. Ingenuity was taxed in getting the surplus workers to and from their homes. About a century ago, the omnibus and then the horse car were temporary solutions, soon followed by the steam railway. In 1867, an elevated railway, using steam at first, was built to relieve congestion on the streets. Twenty years or so later, electricity came to the rescue with surface cars, and, later, electric elevated trains.

The incidence of silicosis is discussed in a report just issued by the Mining Research Laboratory of Birmingham University. The presence of silicosis and dust in coal mines, it is stated, is of great importance to the mining industry on account of the increase in compensation claims which it makes liable. About fifty samples of stone dust were obtained during the year from various collieries throughout Great Britain and analysed for free silica. Up to the present samples have been obtained from collieries producing a total of about 40,000,000 tons of coal a year. Continuation of the work is considered to be desirable, since several collieries appear to be using dust containing more than 35 per cent. free silica. Analysis showed that almost invariably the free silica content of the dust suspended in the air is appreciably less than that in the borings. It is hoped to find out whether this difference is due to the harder crystals of free silica being powdered to a lesser extent than the softer material of the rock. It is believed that the retention by the management of a sample representative of all borings during the driving of a stone heading would place the colliery in a much better position to meet future claims.

Miscellanea.

The new Zeppelin being built in Germany, with a capacity of 7,000,000 cubic feet, will probably be finished by the spring of 1934. She will have accommodation for fifty passengers.

The number of wireless receiving licences issued during August was 225,000. After allowing for those which had expired the total number in force at the end of August was 5,654,400, a net increase of 29,500.

The attendance at the British Association meeting at Leicester was about 1200, which is about the average of recent years, excepting special occasions. The meeting next year will be held in Aberdeen, and the President will be Sir William Hardy, F.R.S.

August shipments of iron and steel from the Tees were heavier than in any month this year with the exception of May, notwithstanding the interruption of the annual holiday period, which caused a cessation of deliveries to certain districts. Last month's loadings totalled 39,682 tons, compared with 35,555 tons in July. The August figures included 12,848 tons of pig iron, 2069 tons of manufactured iron, and 24,765 tons of steel.

A hint for our Electricity Commissioners :—The Dewan Saheb of Junagad has issued an order, states the *Times of India* correspondent, that as electric power is now available all holders of licences for working oil engines in flour and oil mills should note that, unless any reason to the contrary exists in individual cases, their licences will not be renewed after October 31st, 1933, as oil engines are open to objection in towns because of their noise and the deleterious effect of the fumes of their exhaust.

For the first time in the history of the British gas industry, now in its 135th year, an official visit is being paid to the Canadian and American gas industry. On Friday last, September 8th, the President, Mr. Frank P. Tarratt, and sixty members of the Institution of Gas Engineers, left to attend the Twenty-sixth Canadian Gas Convention in Ottawa, and the International Gas Conference and Fifteenth American Gas Convention at the Chicago Centennial International Exposition in Chicago.

During the first week of this month a meeting took place at Berlin between the Ruhr steel works and representatives of the Siegerland iron ore mining industry and the scrap trade, in order to arrive at a definite agreement regarding the disposal of ore from the Sieg, Lahn, and Dill districts and of manganese ore from the Geyer mine. The steel works alone have agreed to accept 36,000 tons of Siegerland ore per annum and 24,000 tons from the Lahn and Dill. Scrap imports are also to be restricted to help the iron ore mines.

The two sintering plants being erected respectively by the Appleby Iron Company, Ltd., at Scunthorpe, and by a Leeds firm at Gunness Wharf, also in the neighbourhood of Scunthorpe, are, says the *Iron and Coal Trades Review*, of the Greenawalt system. The plant for the Appleby Iron Company is to have an initial capacity of 800 tons of sinter per day, with an ultimate extension of the plant to double this capacity. The other Greenawalt sintering plant, under erection at Gunness Wharf, will have a capacity of 75 tons of finished sinter per day.

The Official Returns given to the Electricity Commissioners show that 928,000,000 units of electricity were generated by authorised undertakers in Great Britain during last August, as compared with the revised figure of 816,000,000 units in the corresponding month of 1932. This represents an increase of 112,000,000 units, or 13·7 per cent. The number of working days in the month (excluding Sundays and Bank Holidays) was twenty-six, the same as last year. During the first eight months of 1933, up to the end of August, the total amount of electricity generated by authorised undertakers was 8,329,000,000 units as compared with the revised figure of 7,718,000,000 units for the corresponding period of 1932. This is an increase of 611,000,000 units, or 7·9 per cent.

Improved voltage regulation on many of the rural feeders of the Niagara, Lockport, and Ontario Power Company, has been attained by installation of the recently announced General Electric step-voltage regulators for rural service. The first regulator, obtained in April, was installed with a minimum of time and expense because of its compact arrangement and built-in automatic features. Regulation on the Panama section of the feeder, 7 miles from the step regulator, has been improved from approximately 5·5 per cent. to 1·8 per cent.; on the Niobe section, 8 miles from the regulator, from 5·6 to 1·8 per cent.; and on the Blockville section of the feeder, 2½ miles from the regulator, from 3·6 to 1·8 per cent. Subsequent to this initial installation, the power company purchased two additional step-voltage regulators which are now about to be installed. In the lay-out for all new and re-conditioned existing rural sub-stations, the company is providing space for not only an automatic reclosing feeder breaker, but also a step-voltage regulator.

Although the British Industries Fair does not open until February 19th, the Department of Overseas Trade reports that it has already received applications for more than 90 per cent. of the space occupied by exhibitors at Olympia and in the furniture section at the White City at the last Fair. According to *The Times*, up to August 28th applications were received from 875 prospective exhibitors for a total of 341,118 square feet of exhibition space. At the 1933 Fair 1438 exhibitors in the corresponding groups occupied 378,867 square feet. The greatest increase is in the furniture and basketware group, in which applications have been received from 169 prospective exhibitors for 123,987 square feet of exhibition space, against 98,721 square feet occupied by 179 exhibitors at the 1933 Fair. In the "heavy industries" section at Birmingham advance bookings of space by exhibitors are so far ahead of those last year, and, indeed, in any previous year, that some 55,000 square feet of indoor area is being added immediately to meet pressing demands. Special activity is reported in the gas, electricity, building, and engineering groups.

DIVING AND THE YOUNG ENGINEER.

It is a matter of surprise to us that so few professional engineers whose work is connected with under-water construction have acquired the necessary aptitude and experience to enable them to examine such works in helmet diving dress. There are, of course, a few engineers, particularly of the younger generation, who have gained this useful experience, and it is significant that every engineer probationer in the Department of the Civil Engineer-in-Chief of the Admiralty is now required to attain a reasonable proficiency in diving before his appointment as an assistant civil engineer is confirmed. But we submit that the training is not as general as it should be. We have in mind several instances of serious difficulties occurring, and defective construction resulting, in the carrying out of important sea works through neglect of skilled supervision of operations carried out under water. In two of these cases grossly improper work was done by the contractors concerned, or by divers employed by them, but was only possible by reason of the venality of the diving inspectors employed by the engineers. In neither of these cases did the responsible engineer, or the resident engineer, or any qualified member of the staff, examine the work in diving dress. It is expecting too much of human nature to count on every diver carrying out faithfully and completely the work which he is required to do under water in the absence of adequate check and skilled inspection and supervision. We are not suggesting for one moment that contractors' divers or diving inspectors are, as a class, venal or untrustworthy. On the contrary, they are, as a rule, both competent and reliable. But in every class of workers there are occasional black sheep. No engineer would think of leaving to the sole inspection and supervision of a subordinate workman or inspector, without check, any important work of considerable magnitude if carried out in a position accessible to himself; yet in the case of under-water work this is no infrequent occurrence, and neither the engineer nor his responsible deputy sees the work even in its finished state. This is the opportunity for the untrustworthy workman and the black sheep inspector.

It is not necessary that a young civil engineer should become an experienced and effective under-water craftsman. We do not suggest that he should be specially trained, as are diving ratings in the Royal Navy, to perform difficult and arduous tasks in diving dress. All that is essential is that a young man should be able, when it is necessary, to go under water and to examine for himself the condition of the structure or the work done by divers, and to take a few simple measurements. He should also familiarise himself with what is, and what is not, practicable for a working diver to do under water. Many people, including some engineers, regard diving as a difficult and dangerous art, requiring long training and much practice. This view is far from being a true one, at any rate, in its application to the case of the engineer who is qualified to make inspections in a diving dress. A young man, with sound heart and lungs and with reasonable freedom from adipose tissue, should be capable of going under water in ordinary conditions with safety to himself after two or three simple lessons and trial descents. If engineers responsible for harbour and dock works, reservoirs, the sea outfalls of sewage works, and other similar under-water structures, would arrange for suitable facilities to be given to their pupils or assistants in their employment, the necessary training could be carried out on works without interfering to any material extent with constructional operations. If a young man at the end of a professional diver's spell of work is put into the diver's dress and goes down occasionally, under the instruction and supervision of an experienced man, for a short spell, which need not exceed half an hour at a time, the interruption in or delay to the normal work of the diving crew is of small consequence. We know of an engineer who, as a pupil, was placed by his chief in charge of a small sea work in the course of which the employment of a professional diver was necessary for a few weeks. The diver, on the first occasion when his services were required, having completed his spell of work, returned to the diving boat, whereupon the youngster, with more daring than prudence, and lacking the smallest acquaintance with the technique of diving, informed the professional expert that he proposed to put on the dress and to see for himself what had been done, and what would be required for the next day's work. The diver, after expressing some doubt as to the wisdom of that proceeding, at length agreed to clothe his young superior officer in his diving dress. The youth, full of rash confidence and too conceited to confess his complete inexperience, went over the side of the diving boat, but had not descended far before he found himself in difficulties, and shortly afterwards emerged ignominiously and horizontally, and was hauled to the side of the boat like a distended bladder. With some little difficulty he was up-ended and the friendly linesman was able to relieve the situation by opening the air valve in the diver's helmet which the over-confident beginner had not known how to manipulate. A few words of explanation and kindly advice from the older diver set matters right, and another descent was at once begun and carried through with more satisfactory results. That young man during the two or three weeks that diving operations were in progress went down for a short time every day, and thus acquired experience and confidence as a diver which has been of service to him in all his after career. Now, nearly forty years later, he still occasionally puts on a diving dress for the purpose of examining under-water works. There is an important harbour authority whose chief engineer years ago made a practice of inspecting in diving dress once annually the foundations of the breakwaters for which he was responsible, a practice, we believe, that has been continued by his successors ever since. It was known to the whole of the engineering staff and the professional divers in the employment of the port authority that the chief might at any time decide to inspect personally some piece of work in progress under water. This knowledge stimulated the diving staff, and there is no doubt that thereby the efficiency of divers' inspections and of divers' handiwork was increased. It became a matter of professional pride to the staff engaged on the periodical examination of and repairs to the breakwaters, from the resident engineer down to the youngest working diver, to discover and record every defect of importance lest the vigilant eye of the chief, in the course of his annual inspection, should find some weakness of which he had not previously been informed.

Our advice, then, to young engineers engaged on harbour works and other forms of under-water construction, is to seek every reasonable opportunity to gain personal experience of diving operations, and to those responsible for the carrying out of such works to provide facilities for their young subordinates and encourage them to make use of these. There is no question at all that the engineer who has added diving to his accomplishments possesses an asset which counts in his favour when compared with those who have not taken the pains to acquire the necessary skill and experience. It is, perhaps, as well to mention that the would-be diver should, before making his first descent, submit himself to medical inspection in view of the possibility of some undiscovered constitutional weakness which might operate as a bar to working under compressed air.

Electrical Accidents in Mining.

Few engineering matters have claimed more attention during the past twenty years or so than the use of electricity in mines. The design of flameproof enclosures for switchgear, motors, &c., has given rise to much investigation on the part of manufacturers and independent workers anxious to assist electrical progress. As the recently issued 1932 report of H.M. Electrical Inspector of Mines shows, there is now no technical difficulty or serious economic handicap in providing such enclosures for all descriptions of electrical plant in the sizes that are required for the operation of machinery at or in the vicinity of the coal face. This does not apply, however, to such things as large transformers and motors and certain kinds of controlling gear, which must therefore be kept out of the danger zone. Safety in mines is such an important matter that it is essential to ensure that everything associated with electrification is free from defects and that it is capable of passing recognised tests. While the Inspector has no desire to depreciate the tests made on flameproof apparatus at manufacturers' works, he directs attention to the fact that it was agreed with the British Electrical and Allied Manufacturers' Association some ten years ago that type tests to prove immunity from danger should be carried out by an independent authority. During 1932 much work of this nature was done at the Mines Department testing station at Harpur Hill, Buxton, which took over this duty from the Mining Department of the Sheffield University in 1931. Colliery owners are said to be showing a growing tendency to call for plant certified by the recognised authority, for while it is realised that the constructional features necessary to obtain flameproof enclosures are known to some manufacturers, there are others less well informed, and in the absence of independent tests the purchaser has no guarantee that the plant is safe.

How important it is that mining electrical equipment should conform with official requirements is shown by the report on the explosion at the Garswood Hall Colliery, at which twenty-seven lives were lost. Except for this catastrophe the record for electrical accidents for 1932 would have been the most favourable for many years. The cause of the accident, it will be remembered, was attributed to sparking on the signal bell circuit in use at the time. Tests made after the explosion showed that the spark at the trembler contacts, or that at the point where the signal was given, was capable of igniting an inflammable mixture of firedamp and air. This was by far the most serious accident recorded during the year. There were, in fact, only four other fatal accidents attributable to the use of electricity in mines under the Coal Mines Act, 1911, all being simple cases of electric shock. In each case one person was killed. One occurred on the surface and the remaining three below ground. There were in all sixty notifiable non-fatal accidents and dangerous occurrences attributable directly or indirectly to the use of electricity involving injury to sixty-three persons in addition to six persons who were associated with two of the fatal accidents. Forty-four of these accidents were below ground and sixteen on the surface. That there were no ignitions of firedamp other than the one mentioned speaks well for the work of those who have devoted their attention to the design of flameproof enclosures. Accounts are given of all the fatal accidents and of some of the non-fatal and dangerous occurrences. As usual, they show that even experienced men do foolish things and that regulations are not always complied with. In one case an electrician lost his life by relying on a verbal arrangement on the telephone for the supply to be cut off from a joint box instead of properly isolating the circuit himself. While work was in progress the supply was restored, with the result that the man was killed, whilst his assistant received a dangerous shock. Both men seem to have been in the habit of taking extraordinary risks, for at the inquest the surviving electrician explained that it was their practice to test conductors upon which they were about to work by placing a screw driver across them. Although the method has the merit of simplicity, it is obviously liable to lead to very considerable personal injury and in any case gives no safeguard against subsequent restoration of the pressure. Of the non-fatal accidents one was due to the now all too prevalent practice of using circuit breakers of inadequate rupturing capacity. On the occasion of a fault flaming oil was ejected in considerable quantity through the joint between the switch cover and tank. Three men received burns which necessitated the retention of two of them in hospital. Although in this case the Inspector makes no reference to the fact that the rupturing capacity of switchgear is now often made inadequate by the large capacity of generating and transformer plant that is connected to it, many large consumers have found this to be true. As the Electrical Inspector of Factories has recently explained, there is justification for suggesting that in many cases transforming plant might for the present be limited with more consideration to the load demanded, and that the best interests of the authorised undertakers will be served by advising their industrial consumers of the supply conditions that obtain.

But if the report of the Electrical Inspector of Mines indicates the desirability of one change more than another, it surely is in the direction of better supervision and the employment of properly qualified men. Contrary to regulations, men with no electrical knowledge are apparently allowed to carry out work in the vicinity of live conductors without any control over their actions. Cases of this kind may not be numerous, but it is undesirable that they should occur at all. A story is told, for example, of a labourer being left to whitewash the walls in a transformer sub-station whilst the transformer was alive. The assumption apparently was that as he had whitewashed other sub-stations in which there were no exposed live parts, he would be safe under the more dangerous conditions, but unfortunately he was electrocuted. Another case reported points to the obvious fact that when supervisors are provided they should be individuals qualified for the job. A young man, variously described as an electrician's mate, or as a motor man, was told to remain with some bricklayers whilst they performed the work of filling in some holes in a cubicle containing a 2,000-kVA, 10,000/3,000-volt transformer. Not content with the task allotted to him, however, he proceeded to dust the top of the transformer and in doing so received a severe shock and burn. While it would be wrong to assert that for the most part colliery electricians are incompetent, it is clear that they are not always up to the standard that the work demands. Discussing this matter from the point of view of underground maintenance work, in a paper read before four local centres of the I.E.E., Mr. Andrew R. Cooper states that as a general rule men who are capable of the work are not attracted by the conditions, whilst those who are prepared to put up with the disadvantages are of too low a grade to give the service required. Mr. Cooper's recommendations are that certification by some recognised authority of all colliery electricians should become compulsory and that educational authorities should arrange for special electrical courses for young men who desire to specialise in colliery work. Such courses are already available at universities, mining schools, and some technical schools, but there is ample room for more widespread evening instruction to meet the requirements of those who have to combine practical activities with study.

Literature.

Reinforced Concrete Bridge Design. By C. S. Chettoe, B.Sc. (Eng.), M. Inst. C.E., and Haddon C. Adams, M.C., M.A., Assoc. M. Inst. C.E. London: Chapman and Hall, Ltd. 1933. Price 42s.

A book which is indicated by its title as one relating to a particular type of bridge or to bridge design and construction with one kind of material, may reasonably be confined to considerations proper to the employment of the type or material. On the other hand, in such a work the value of this exposition of one part of the art of bridge building may be enhanced, and a sense of the relation of the particular practice to practice generally be conveyed to the reader if it be written in the light of main principles and with the broader aspects of bridge problems present in the mind of its author. Some discussion of problems precedent to the actual designing of the structure, such as those relating to choice of site and choice of type, may considerably add to the value of the book, if so directed as to bear upon the question of the suitability in typical cases of particular forms of the type under consideration, or of the types or forms available with the material named in the title.

In the first respect there can be placed to the credit of the authors of the work under review an excellent chapter on the æsthetics of bridge design, beautifully and instructively illustrated with photographs of bridges; the opening chapter on structural theory; and, facing page 1, a most apt quotation from Ruskin's "The Stones of Venice." Further, the spirit in which the book is written and in which the student should approach the subject is well expressed in the opening paragraph of the preface, in the words: "As both an art and a science, bridge-building is once more coming into its own. It flourished as an art, became a science, and the art was in danger of being forgotten, except by the great bridge-builders in whom science and art were reconciled. To-day, there are signs that the great tradition is to be resumed, and we may with reason hope that 'the best is yet to be'"

As regards problems precedent to actual designing, there is, excepting the matter in the chapters already mentioned and—disappointing in view of a reference in the preface to the subject of choice of type—only about 1½ pages relating to the site and, very briefly to river flow data, the observations being suggestive rather than instructive. There are, of course, a number of passages, in various chapters, which are of some significance with respect to the type of span and the forms suitable under given conditions.

As regards the main exposition, it is sufficient to remark that it has the vigour and clarity to be expected of Mr. Chettoe and Mr. Adams, is well balanced and adequately covers the subject. Major allotments of space are made for treatment of the essentials of reinforced concrete design, of arches, and of substructures. There is a useful chapter on bridge strengthening and widening, and one on vertical curves, horizontal curves and super-elevation. Dealing briefly with the modulus of elasticity of concrete, the authors do not discuss recent researches respecting the variability of the modulus with differences in the nature and proportion of fine aggregate, the water content, the age of the concrete, the disposition of the reinforcement, and other factors. In other respects the significance of the modulus is adequately explained.

This well-written volume of 400 large octavo pages, liberally and usefully illustrated, may be commended as suiting the requirements of both students and bridge engineers.

The Chemistry and Physics of Clays. By Alfred B. Searle. Second edition. London: Ernest Benn, Ltd. Price 55s.

Mr. Searle's work has for long been recognised as one of the most authoritative books on the subject of clays in this or any other language. The revision made in the present second edition has been exceptionally thorough, for we have noticed very few paragraphs which have simply been reproduced from the 1923 edition. This edition also contains several new features. The amount of practical and valuable information that is compressed by Mr. Searle into a comparatively small compass is remarkable, and we have no hesitation in prophesying for this edition an even wider circle of readers than the earlier edition both merited and obtained. No spectacular advance has been recorded in the study of clays during the period covered since the publication of the first edition, but further application has been made of X-ray spectrographic methods and the more general use of physico-chemical technique which are furnishing data of considerable practical importance. The physical and chemical properties of fired kaolins have been investigated by the U.S.A. Bureau of Standards, in which it has been found that the excessive coefficient of expansion of certain fired clays is caused very largely by the presence of cristobalite. Researches of German origin have dealt with the viscosity of clays, together with the influence on viscosity of silicate, carbonate, and caustic alkali ingredients. Italian investigators have studied the action of certain sulphates in flocculating clay suspensions, and also the *rôle* of deflocculents. Some investigations carried out in this country have dealt with the practical applications of deflocculated clay-slip bonds, the effect of various ingredients on the properties of silica bricks, the influence of grading on their porosity, and comparison of the properties of lime and clay-bonded silica bricks prepared from calcined ganister. These and many other investigations are referred to by the author in his volume, which is written in a clear style and with a wide vision.

Commercial Motor Road Transport. By L. M. Meyrick-Jones. London: Sir Isaac Pitman and Sons, Ltd. 1933. Price 15s.

The great expansion of road transport since the war, and the considerable changes in design and in the laws governing transport undertakings, have undoubtedly made it desirable that books on the operation of road transport should be written and published. The book under review can be regarded as up to date in most essentials. Besides an opening chapter dealing with certain general considerations, such as the importance of adequate mileage and the influence of working conditions, the volume is divided into four parts—Mechanical; the Business and Commercial Aspect; Working and Upkeep, and Legal. The latter three parts are likely to be the most useful. In Part II., for instance, working costs for types of vehicles from 5 cwt. to 12 tons are worked out for petrol, heavy oil, steam and electric vehicles. No doubt some operators will challenge the figures or the arrangement of the various items under "running" and "standing" costs. For instance, the author puts the wages of the driver and his assistant under "standing" costs, whereas some operators no doubt would regard this expense as a "running" charge. Worked figures of this nature are bound to be controversial, but they are, nevertheless, a very useful guide. In this section, too, the author has many suggestions to make with regard to the fixing of rates for the carriage of goods and to the recording of the work and other such details. Nor are passenger vehicles neglected, and a chapter is devoted to services and fares. The next section—Part III.—as its title implies, is concerned with upkeep. In these days it is almost a necessity that a work on commercial road transport should have a section devoted to legal questions. In this book the section is kept as short as possible, subject to giving all the needful facts. These three sections make the book a valuable one, but the necessity for including the first—Part I., Mechanical—seems doubtful. It is, in any case, a very elementary sketch of the mechanical construction of road vehicles, and the author might have been better advised to "leave well alone" and refer his readers to books specially devoted to the subject, of which there are many. Sometimes, indeed, the reader is tempted to doubt whether the author's thermodynamical knowledge is sound as, when he states "... as the figure in the assumed example is fairly representative of the petrol engine, which averages 20–25 per cent. [thermal] efficiency, it will be realised that as yet we are able to convert into useful work only a mere fraction of the heat available in the fuel." Again, in explanation of the reason for the lower thermal efficiency of the steam engine, he points out as a source of loss of heat "... a lot is absorbed by the conversion of the water into steam." It is charitable to believe that such remarks as these arise from a desire to put thermodynamical principles into very simple language which may be understood by those with no knowledge of the subject, but, nevertheless, such sentences give rise in the reader's mind to a doubt as to the ability of the author to write as an authority. Apart from Part I., however, the book may be recommended as a useful contribution to a subject not yet as completely covered by literature as it might be.

SHORT NOTICES.

Power Plant Engineering and Design. By Frederick T. Morse. London: Chapman and Hall. Price 30s.—An attempt is made in this volume, which is devoted entirely to American practice, to present a thorough study of electric generating stations, including public service, industrial and other plants. Although the volume is primarily intended for the use of students, the author hopes that it will also prove of value to the practising engineer. Special attention is paid to the study of vapour cycles and heat balances. The early chapters cover the variable load problem, power plant economies, and power plant buildings. Oil engine and hydro-electric plant is then considered, and the remainder of the volume is devoted to steam plant. Steam boilers, prime movers, condensers, feed water and piping systems are naturally covered. Although the limited space of one volume makes it impossible to deal with many of the minor details of power plant equipment and lay-out, the author has succeeded in covering the main things that go to make up a power station. There are many instructive pictures and drawings which serve to familiarise students with modern power plant practice. Problems relating to many branches of the subject are set and answered. The electrical section of the volume covers generators, switchgear, and transformers. Instruments of all kinds are dealt with in a separate chapter, which brings the volume to a close.

Elements of Power Generation. By Arthur M. Greene, jun. New York: John Wiley and Sons, Inc. London: Chapman and Hall, Ltd. 1933. Price 20s.—It seems the general rule nowadays to publish American technical books in England and, presumably, English technical books in America, whether they are really suitable for the country or not. That is not to say that the book under discussion is not suitable for this country, for it is not improbable that it may prove quite popular. But for one at least of the purposes for which it was written in America it may become a source of error in this country. One of the author's aims was to give to the reader an engineering vocabulary and not all American terms are equally applicable in this country. In pursuance of this purpose most of the technical terms throughout the book are printed in a bold black type. The text throughout is descriptive rather than theoretical, as it is the belief of the author that a knowledge of the form and use of engineering devices should precede the study of the technical details of their design. As the book is concerned more particularly with power stations, steam is the predominating influence, as may indeed be inferred from the following list of chapter headings:—Power Generation and Sources of Power; Combustion of Fuels; Boilers; Boiler Details and

Accessories; Boiler-house Appliances; Power from Steam or Gas; Machine Details; Valves—Valve Gears and Governors. The book is profusely illustrated mainly by drawings and an index is included at the end.

Power Economy in the Factory. By J. C. Todman. London: Sir Isaac Pitman and Sons, Ltd. 1932. Price 7s. 6d.—This is another of the little Pitman technical manuals, published at a price within the reach of all. It is like many other books of the same class published by Pitman's, of a more or less elementary nature, and its writing was prompted by the author's opinion that in a great many and probably a majority of the factories at work to-day money is being wasted continuously by various losses in the generation and transmission of power. The first three chapters are devoted to simple mechanics, heat, and magnetism and electricity respectively. There follow chapters on furnaces, boilers, boiler-house measuring instruments, and the steam engine. Internal combustion engines, electrical generators, the control and distribution of electrical energy, and electric motors are dealt with in following chapters. In the remainder of the book its subject is further developed. Chapters on the improvement of power factor, power distribution, and the distribution of steam and gas are followed by further sections dealing with compressed air and hydraulic power. Power and the cost accountant and units of measurement bring the book to a close.

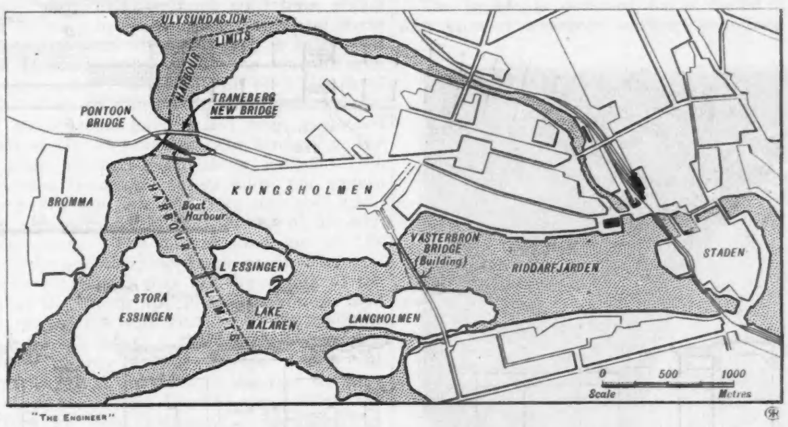
SIXTY YEARS AGO.

WORDS, particularly technical words, have a strange way of changing their meaning with the passage of time, or of being applied in one connection only to be forgotten and revived at some later date in an entirely different sense. Thirty years or so hence, the writer of this note, whoever he may be, will probably be speculating on the curious use in our pages of the word "aerodrome" to signify not a flying ground, but a flying machine. To-day, turning back to our issue of September 19th, 1873, we alight on two equally curious instances of philological transmutation. The first leading article in that issue bore the cryptic title "Calorimeter in Locomotive Engine Boilers." We have to confess to some measure of surprise that even sixty years ago the word "calorimeter" could be used, in a technical or scientific discussion, otherwise than as meaning an instrument for measuring quantities of heat. Yet, in our article it was clearly and specifically defined as signifying "the gross aggregate area of escape through the flues of a boiler." Our article was, in fact, concerned with current practice as regarded the proportioning of the cross-sectional area of the boiler tubes to the grate area in locomotives. Our second example occurs in a succeeding leading article entitled "Brindley's Dictum as to Rivers and Canals." Glancing down it the term *auto mobiles* catches our eye. It was not, however, employed to designate mechanically propelled road vehicles, but referred to one of three methods—the others being *vannes mobiles* and *hausses mobiles*—which had been in use in France for the previous seventy years for dealing with the flood waters of navigable rivers. The technical interest of neither leading article has survived. The argument of the first was based on the faulty, but, at that time, universally accepted belief that "the more slowly the heated gas can be made to traverse the tubes the better." The second dealt with Brindley's "celebrated maxim," to the effect that the use of rivers was to feed navigable canals. In a previous issue we had described this saying as being not far removed from nonsense, although it was often repeated as providing an instance of the mental vigour of an untutored genius. A correspondent had taken exception to our opinion and had maintained that Brindley's utterance contained profound wisdom. We replied that it might be so if the remark were confined to English rivers, but that Brindley, while he possessed strong mother wit, had had narrow opportunities for acquiring information and that his saying could not possibly be held to be applicable to many great rivers which, to him, could have been little more than names. . . . To round off our survey of the subjects which, at the moment, were engaging our attention, we may add that the title of a third leading article in the same issue was "The Kitchen Middens of London." This article is interesting to-day because of the picture which it presents of domestic sanitary conditions in the Metropolis sixty to seventy years ago. The cesspool had nearly disappeared, but the "dust pit," cleared by contractors at nominally frequent intervals, survived. We argued in favour of the abolition of fixed brick or wooden structures into which to shoot the household refuse, where it would await the uncertain and perfunctory attention of the dustmen, and their replacement by light sheet metal boxes—the dustbins of to-day, in fact—capable of holding not more than two or three days' "dust."

The Traneberg Arch Bridge, Stockholm.

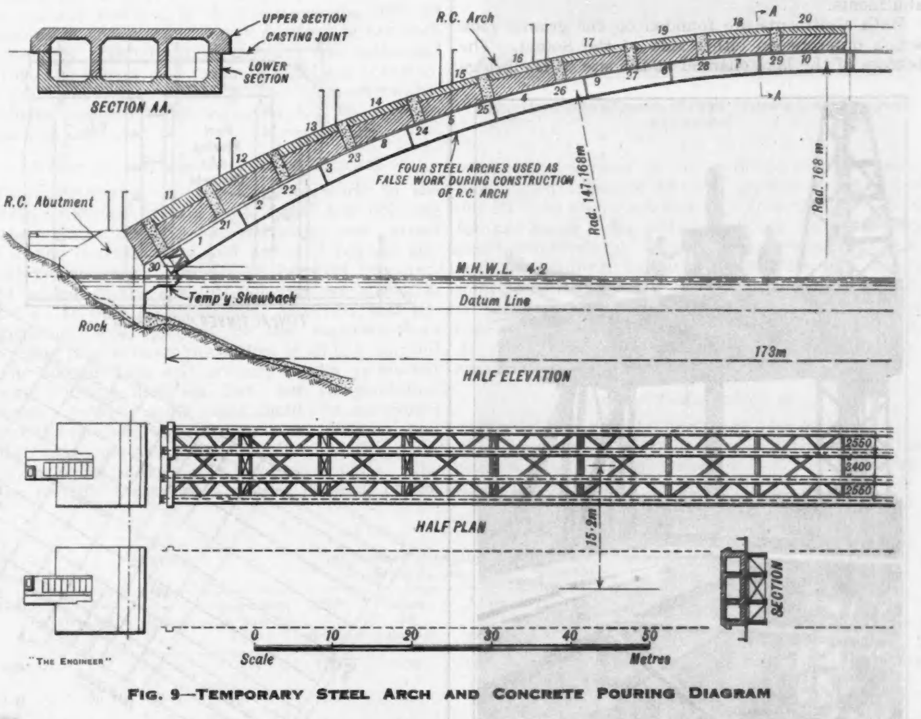
◆

FOR many years the City of Stockholm has been extending its residential area westward. In Bromma, a district lying to the west of, and separated from, Kungsholmen by the Traneberg Sound, some 30,000 people have settled in the suburbs and garden cities which have grown up since the beginning of the present century when the Municipality of Stockholm bought large areas of land in the district. A large proportion of the residents have their daily work in the business quarters of Stockholm, and their only means of communication with the city is, at present, by way of a pontoon bridge, 187 m. in length and 8·5 m. wide, which spans the Traneberg Sound. The crossing of the Sound, one of the many narrow passages in Lake Mälaren (Fig. 8) has always been made by means of a pontoon bridge since the first of these was constructed in 1787. The present bridge was opened for traffic in 1914; it has a movable section which permits the passage of shipping through the Sound. The bridge, which carries two tramway tracks, is now too narrow to accommodate the rapidly increasing volume of traffic, and it is incapable in its present condition of carrying the heavy road vehicles and electric rail cars now in common use in the Stockholm district. The delays due to the opening of the bridge for shipping also result in inconvenience to road traffic.



"THE ENGINEER"

FIG. 8—PLAN SHOWING POSITIONS OF NEW BRIDGES



"THE ENGINEER"

FIG. 9—TEMPORARY STEEL ARCH AND CONCRETE POURING DIAGRAM

Early in 1931 the Stockholm Harbour Authority decided to replace the pontoon bridge by a single span reinforced concrete arch bridge over the waterway with viaduct approaches which would be sufficient for all the requirements of modern road traffic and provide also for two lines of suburban electric railway track. It should be explained that the Harbour Authority is responsible for the construction of all road bridges crossing the several arms of the sea, and the channels of Lake Mälaren within the limits of the harbour area. Although the Harbour Authority is responsible for the design and construction of such bridges, the cost of the work is borne by the City Authorities, and the expense is, therefore, not a burden which has to be borne by the shipping trade of the port.

VASTERBRON BRIDGE.

It may here be mentioned that the Harbour Authority is, concurrently with the building of the Traneberg Bridge, building another bridge across the Sound which separates Kungsholmen from Langholmen. This bridge—the Vasterbron (see Fig. 8)—consists of two steel arches spanning the waterway with a pier in the middle of the channel and approach viaducts and forms a part of the scheme of new road connections between Kungsholmen and Södermalm. The two arches have spans of 168 m. and 204 m. respectively. The total length is about 600 m.

TRANEBERG BRIDGE.

The new Traneberg Bridge (see page 258 and Figs. 9, etc.) is situated about 120 m. north of the pontoon bridge, and has a total length, including the viaduct approaches, of 580 m. It is of special interest not only because the arch has a greater span than any other reinforced concrete arch yet built, but also on account of the novel method of erection employed by the builders. The length of the viaducts is 215 m. on one side, and 145 m. on the other. The reinforced concrete arch over the waterway has a theoretical span of 181 m. and a clear span between abutments of 178·4 m. The rise of the arch is 27 m., which gives a clear headway for shipping of 26 m. above mean high-water level over a width of 45 m. The bridge has an overall width between balustrades of 27·5 m., of which 12 m. are devoted to roadway, 8·5 m. to the two tracks of the Suburban Electric Railway, and the balance of 7 m. is occupied by two footpaths and two bicycle tracks (Fig. 10). The road surface has a gradient of 1 in 30 in each direction from the centre of the arch span. Portions of each of the two approach viaducts are built to a curvature in plan of 300 m. radius.

The arch span consists of twin reinforced concrete arches placed at a clear distance from each other of 6·2 m. Each arch has a width of 9 m., and a depth of 5 m. at the abutments and 3 m. at the crown. The arch is designed as a hollow rectangular reinforced structure with two dividing walls. The slab thicknesses at the crown are 0·45 m. for the top slab and 0·50 m. for the lower slab. The side walls are 0·50 m. thick, and the division walls 0·40 m. The dimensions of the slabs and vertical walls are increased towards the haunches. The enclosed rectangular spaces formed by the walls and slabs of the arch ribs will be utilised for gas and water mains, and electric supply cables. The middle space in each arch is continued through the concrete abutments.

Both abutments are founded on the granite rock which outcrops on either side of the Sound. The bottom of the lake channel at the site of the bridge between the abutment foundations consists of soft clay and gravel or sandy clay overlying the granite rock, which, at its lowest level, is 33 m. below mean high-water level. The depth of water in the middle of the Sound is about 16 m.

The deck of the bridge is carried on a system of welded steel longitudinal and transverse girders, supported by thin reinforced concrete pillars which have the same width as the concrete arches and a maximum thickness of 0·9 m., and, at the crown of the arch span, by rolled steel joists. The approach viaducts are constructed in a similar manner to the superstructure of the arch span, the supporting columns or piers being similar to those which rise above the arch, except at the western end of the approach on the Traneberg side, where the superstructure is of reinforced concrete carried on rectangular columns of similar material.

FIG. 11—HYDRAULIC JACKS ON TOWER FOR RAISING STEEL ARCH

STEEL ARCH FALSE-WORK.

The false-work or scaffolding employed for the construction of the twin concrete arches consisted of a steel arch which, after having been used for the first concrete arch, was moved to the position of the second arch and used over again. This temporary arch (Fig. 9) was built up of four riveted steel plate arch ribs, 2·4 m. deep, spaced apart transversely 2·55m.—3·40m.—2·55m. The arch ribs were continuous from abutment to abutment and had no hinges. The span of the steel arch, measured to the centres of the supports, was 172 m. The abutments for the steel arch were provided by temporary concrete skewbacks cantilevered out from the permanent abutments of the concrete arches below the permanent skewbacks. The four ribs of the steel arch were connected together and stiffened by angle bar cross bracing (Fig. 9).

FIG. 12—DETAILS OF STEEL REINFORCEMENT AT HAUNCH OF ARCH, AND TYPICAL SHUTTERING

In preparing the scheme for the erection of the bridge before tenders were obtained, consideration was given to a scheme of false-work comprising temporary steel arches of three spans, respectively 24 m., 120 m., and 24 m., supported on temporary foundations in the channel. This design was suggested, as the preliminary estimates had shown that steel false-work in one span would probably be more expensive than the alternative. When tenders for the work were invited, tenderers were also at liberty to submit further alternative proposals for the temporary works, and it was then found that a single steel arch span would cost about the same as three arches. As a single-span temporary arch offered several practical advantages, a tender was accepted on this basis of construction. It may be remarked that the alternative adopted has proved somewhat more expensive to the contractors than had been expected.

The steel arch ribs were built up at the works and dispatched in sections of 11 m. length and transported by barge to a wharf 2 kiloms. from the bridge. The sections were there riveted together to form half-spans of two ribs in each (Fig. 2, p. 258), and were then brought to the site of the bridge on two sections of a small floating dock. A steel tower was then built up on the deck of two other sections of the floating dock, which were moored in the correct position midway between the abutments (Figs. 2 and 3). The four half-spans, placed successively on the two sections of the floating dock, were manœuvred into position between the abutments and the floating erection tower, the skewback end of each semi-arch being placed in contact with a temporary support on the abutment. The crown end of each half-span was suspended from the tower by link plates and raised by means of hydraulic jacks (Figs. 2 and 11). When all the four half-spans had been lifted to the correct height, they were coupled together with a temporary ball link at the crown, and, after careful adjustments had been made with hydraulic jacks at the abutments (Fig. 5) and the final bearings had been built in, the arches were riveted together at the crown. Finally, the cross bracings between the two pairs of ribs were erected and riveted (Fig. 3).

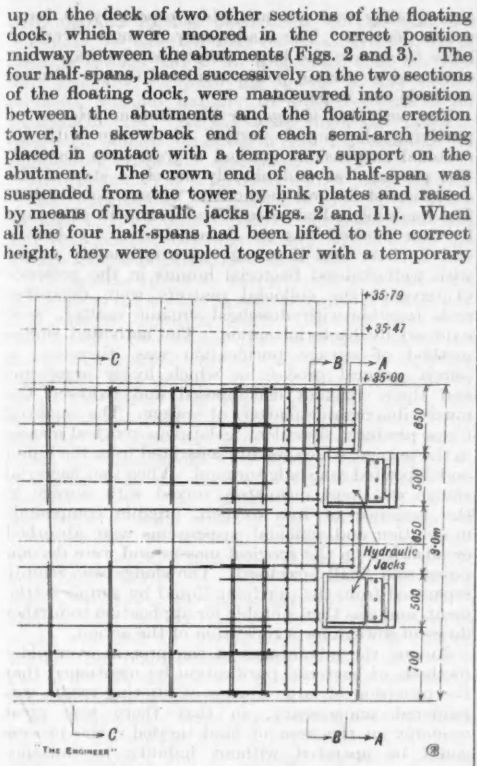

FIG. 13—DETAIL OF REINFORCEMENT AT CROWN OF ARCH

CONCRETING OF ARCHES.

The concreting of the arches was carried out in two stages, first, the lower slab and the side walls, and secondly, the inner partition walls and the top slab. The concrete was poured in monolithic sections of lengths varying from 7·2 m. to 8·5 m., and in a suitable order for equalising the loading of the steel arches (Fig. 9). An interspace of 1·2 m. was left between the monolithic sections to provide for shrinkage. These joints were not filled until the concrete in the monoliths had set and hardened and was at least eight days old.

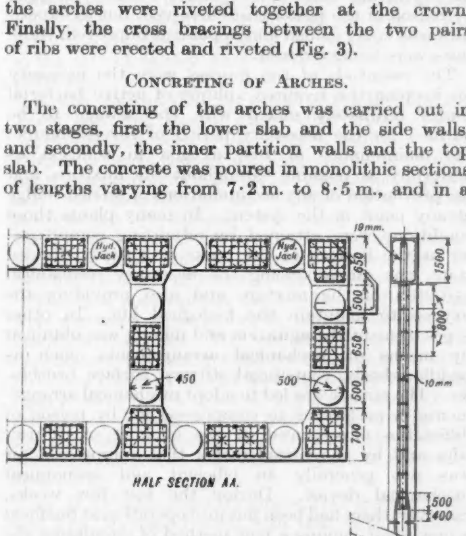

FIG. 14—HYDRAULIC JACKS AT CROWN OF ARCH AND DETAILS OF PILLARS

All the shuttering and form work for the concrete was of timber; a typical section of the form work is shown in Fig. 12, and a view is reproduced in Fig. 6.

REINFORCEMENT.

The bridge is not very heavily reinforced as tension will occur seldom and only in the lower slab at the abutments. In each arch there is a reinforcement of 108 round M.S. bars, 22 mm. diameter, which are lapped in the construction interspaces without hooks. In addition there is some reinforcement at right angles to the main bars. Details of portions of the steel reinforcement are reproduced in Figs. 12, 13, and 14. On an average the steel reinforcement is about 60 kilos. per cubic metre of finished concrete.

REMOVAL OF CENTERING.

The concreting of the first arch was completed about Christmas, 1932, and about two months later, in March, 1933, the temporary steel arch was removed in the following manner:—Eighteen hydraulic jacks, each of 330 tons capacity, were placed in position in recesses formed in the crown of the arch (Figs. 7, 13 and 14). Pressure was applied by these jacks in a direction parallel to the line of thrust at the crown until the arch had lifted about 0·17 m. at the crown and the crown had opened 0·11 m. at the top and 0·10 m. at the bottom. The horizontal pressure thus applied amounted to about 6000 tons, which was about 700 tons in excess of the horizontal stress due to the dead load when the arch is in normal condition. It was then found that the concrete arch had been raised from the steel arch on a length of 20 m. at the crown and 25 m. adjoining the abutments. Electrical strain-stress gauges had been concreted in the arch at the abutments. The stresses in the concrete were registered on these gauges; the stress increased from zero to 49 kilos. per square centimetre in the top slab, and from zero to 3 kilos. per square centimetre in the bottom slab of the arch at the abutments. The gauges used are of the "Carlson" type and also record temperature changes.

It may be mentioned that the depression of the steel arch at the crown due to the maximum load supported during the construction of the concrete arch had been calculated to be 0·20 m. Actually, the measured depression was 0·18 m. After the steel arches had been unloaded in the way we have just described, they were lowered away from the concrete arch by eight hydraulic jacks placed at the abutments and traversed on rollers to the parallel position for the construction of the second concrete arch. Hydraulic jacks were used for moving the steelwork to the second position (Figs. 4 and 15). The temporary steel arch, together with the timber staging carried by it, weighed about 1200 tons.

In May, 1933—that is, about two months after the steel arch had been removed from the first concrete arch—the crown of the latter was lowered about 0·082 m. by applying a negative bending moment at the crown so as to compensate for the increased stresses due to weight of roadway, live loads, and temperature variations. This bending moment was obtained by applying four additional hydraulic jacks at the crown section, bringing the total number of jacks up to twenty-two of 330 tons each. The moment was produced by the jacks exerting different pressures at the top and lower portions of the arch respectively. The bending moment was estimated at 1590 ton-metres, and, when it had been obtained, the joint was concreted in. A short time afterwards the jacks were run down, removed, and the recesses filled with concrete.

VIADUCT AND ARCH SUPERSTRUCTURE.

The construction of the concrete work in the spandril columns of the arch span, the columns of the viaduct and the superstructure was carried out in the ordinary way and does not require any detailed description. Details of the steel reinforcement of one of the spandril columns are shown in Fig. 14. It may be mentioned, however, that the longitudinal steel girders of the superstructure rest freely (but without possibility of sliding motion) on the column tops and are not rigidly connected thereto. The pillars, in fact, act as pendulum columns. Another point which should be mentioned is that the roadway superstructure on the arch span is discontinuous along the middle line (Fig. 10), the joint being masked by a steel cover plate. The reason for this construction is that one-half of the roadway rests entirely on one concrete arch, but the other half is carried by both arches. The bridge being aligned almost due east and west, there may be at certain times an appreciable elevation of the crown of the south arch above the level of the north arch owing to temperature differences, and the articulation of the road surface provides for this possible inequality. This articulation also provides for the unsymmetrical distribution of the live loads on the bridge, a factor of even greater practical importance than the temperature differences.

Provision is made for expansion and contraction of the bridge floor system by means of expansion joints at the points 6 and 38 and at pillars 16 and 27 (see plan, Fig. 10). At pillars 16 and 27 the supports for each longitudinal girder consist of roller bearings, and at points 21 and 22 there is also a joint in the floor system.

CONCRETE SUPPLY.

The whole of the concrete used in the bridge was gauged and mixed under standardised conditions in a central concrete factory in Kungsholmen, and transported to the works in portable containers on motor lorries. The concrete and other materials were distributed to the working positions on the arch and in parts of the viaduct by a wire ropeway crossing the Sound on the line of the bridge.

TRAFFIC LOADING.

The bridge is designed for a traffic loading of four lines of transport vehicles, including a 20-ton road roller, abreast on the carriage roadway, each line corresponding to an ideal loading consisting of one 11 tons axle load and two linear loads of 0·50 ton per lineal metre of the traffic file spaced 1·7 m. apart transversely. For the cycle tracks and footpaths a uniform loading of 400 kilos. per square metre is allowed. The loading provided for on the two tracks of the suburban railway is a 68-ton motor coach with three trailing coaches of 40 tons each. All the above loads are increased by a suitable allowance in each case for impact.

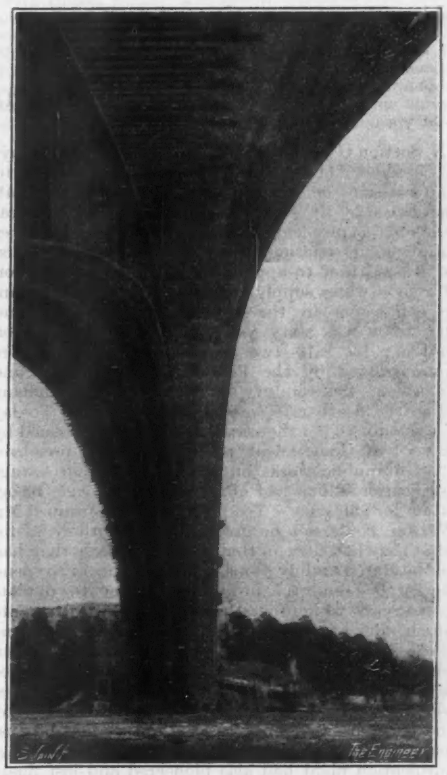

FIG. 15—TRAVERSING STEEL ARCH TO SECOND POSITION

CONCRETE MIXTURES, &c.

The following table shows the proportions of the different mixtures of concrete used in the bridge, the compressive strength obtained and the maximum stress allowed for in designing the structure :—

Cement, kils. per cu. m.	Mixture.			Compressive strength in kilos. per sq. cm.			Permissible stress, kilos per sq. cm.	Position of concrete.
	Cement.	Sand.	Stone size in mm. 7–70.	After 7 days.	After 28 days.	After 90 days.		
300	1	3·0	3·3	160	300	330	60	Abutments of the viaduct approach (Kungsholmen side). Columns
330	1	2·9	2·7	180	320	360	60	Bridge floor
350	1	2·7	2·5	200	340	390	80	Water pipe chambers in the arch abutments
365	1	2·6	2·5	220	430	450	100	The arches and their abutments
400	1	2·2	2·2	250	450	480	120	Portion of the crown of the arches

QUANTITIES OF MATERIALS.

The total amount of concrete used in the construction of the bridge will be about 22,000 cubic metres. The weight of the steel reinforcement is 1400 tons, and of the welded steel girders and joists in the superstructure 1300 tons. The temporary steel arch structure weighed about 1000 tons, and 60,000 square metres of timber shuttering were used for the concrete construction. The total cost of the bridge, including the approach viaducts, will be about 5,300,000 kroner (about £290,000 at par).

Conclusion.

On page 258 and elsewhere we reproduce several photographic views of the bridge taken during construction. Fig. 2 is a view of the floating erection tower with one semi-arch raised and another being lifted. Fig. 11 shows the hydraulic jacks and link plates at the top of the erection tower, and Fig. 3 is a view of the arch when all the four parts were in position. Fig. 5 shows the steel arch being adjusted at one of the abutments by hydraulic jacks, and Fig. 15 is a view taken from the ice in the channel beneath the bridge while the temporary steel arch was being traversed to the second position. Another view of the traversing operation is shown in Fig. 4. Fig. 6 is a view of the first concrete arch during construction. Fig. 7 is from a photograph taken inside one of the rectangular compartments at the crown of the concrete arch while the hydraulic jacks were being pumped up. A view of the bridge works in July, 1933, is shown in Fig. 1.

The bridge is expected to be opened for traffic in the early summer of 1934; when we inspected the works at the end of June last, the erection of the superstructure of the viaduct was in progress, and the construction of the second concrete arch was well advanced. The bridge was designed by, and its construction is being carried out under the supervision of, the Engineering Department of the Stockholm Harbour Board. We are especially indebted to Major Ernst Nilsson, the engineer responsible for the design, for the use of plans and photographs, and for the information upon which our description of the works is based. The construction of the bridge is being carried out departmentally by the staff of the Stockholm Harbour Board, no general contractor being employed.

Sewage Disposal.

BRITISH ASSOCIATION, LEICESTER.

In Section G of the British Association on Monday, September 11th, the whole morning was devoted to a discussion on sewage treatment and disposal, introduced by Mr. J. D. Watson, who in a brief general talk on the problems associated with a good water supply in its relation to sewage treatment and disposal, said that to appreciate what the introduction of a good water supply to a great town might mean, we could compare the state of our largest Midland city as it was sixty years ago with its condition to-day. In 1870 two Government officials were commissioned by the Privy Council to write and report on the sanitary condition of Birmingham, when the death rate was 23 per thousand. To-day it was only 10 per thousand, and the report issued by those two Government officials was the precursor of great public works on water supply and sewage purification which had obtained a world-wide recognition for efficiency. Too much credit, continued Mr. Watson, could not be given to local authorities for what they had done in that respect, because they had not hesitated unduly to make experiments or to spend money on doubtful projects in order to obviate nuisances or to improve the condition of streams into which effluents were discharged. Birmingham and Sheffield were notable examples of that. To their credit, he said, those local authorities were prepared to face criticism rather than perpetuate a process which could be regarded as inferior. Nor had failures and losses been confined to local authorities, because manufacturers of machinery associated with sewage purification plant had also pioneered and lost financially as the result of their zeal for progress. Bio-aeration had proved to be an easy way of controlling the smell and fly nuisance without impairing efficiency or interfering with oxidation. That process was generally less costly to instal than the bacteria bed process, but maintenance costs were higher. There was one thing, however, which should not be overlooked, namely, bio-aeration plants required more scientific management than was necessary in the case of the bacteria bed or of land irrigation.

Commenting upon the remarks of the Royal Commission on Sewage Disposal in 1905 to what is now termed "sludge digestion"—a natural and odourless method of treating sludges—Mr. Watson said that with the exception of Birmingham, where the work was done on a large scale, that method of treatment had not been adopted in this country until recently. It was recognised by scientists to be reliable, but in certain circumstances it might not be economical. Nevertheless, it would be doubtful economy if preventable stench were allowed to persist or to interfere with the health and comfort of the people. As a possible pecuniary advantage of that process, it was pointed out that it yielded a valuable gas, capable of generating power, and that the dry residuum might be used as an organic base for a fertiliser, since it was devoid of fat and possessed from 2½ to 4 per cent. of nitrogen. Mr. Watson also recalled that he himself brought to the notice of the British Association in Edinburgh in 1921 the potential value of methane gas produced by sewage sludge when a 25 H.P. engine had just been started in Birmingham using that gas. Since that time sewage gas engines had been installed up to about 1000 H.P.

Finally, Mr. Watson in his introduction to the discussion, said that whilst public opinion was laying greater stress upon the need for conservation of our comparatively few pure streams, it was also beginning to realise that too many small sewage works were being dotted over the country. The time had come, he said, when the administrator should see that fewer, better, and more scientifically designed and managed works were substituted wherever possible. The first example of co-ordination amongst local authorities was that of Croydon and fourteen other towns which united to create a scheme of sewage and water supply. That example was followed by others, but it had not been popular with authorities unless it could be shown that they would not suffer financially. The Local Government Act of 1929 encouraged local authorities to take a far-seeing view and invited the County Councils to help to overcome difficulties, which without that help could not be dealt with. At the instigation of the great majority of the local authorities in West Middlesex, the Middlesex County Council promoted a Bill in Parliament to construct intercepting sewers to convey to one site for purification, sewage and surface water equal in volume to 240 gallons per head per day of a potential population of two million people. In addition to arresting the pollution of a number of rivers, the immediate effect of that scheme would be to abolish twenty-seven public sewage works as well as several private works. That Bill became an Act in 1931, and the authorised works, now in course of construction,* ought to be completed before the end of 1935.

Mr. H. F. Atter (Clerk and Solicitor to the West Riding of Yorkshire Rivers Board) followed with a paper on "The Legal Aspect of River Pollution, with Special Reference to the Rivers Pollution Prevention Acts," pointing out that whilst the Joint Advisory Committee on River Pollution in 1928 reported that there was no lack of administrative authority for enforcing the law, it was admitted on all hands that many of our rivers were seriously polluted, and that the law designed to prevent avoidable contamination was to a large extent not put into operation.

Dealing with the purification of sewage by natural processes, Professor W. E. Adeney and Dr. A. G. G. Leonard gave the results of laboratory experiments which elucidate certain fundamental principles involved in the aerobic purification of sewage liquors. By the extraction and analysis of the gases occurring in polluted waters undergoing oxidation, it had been possible, they said, to study the changes accompanying the destruction of impurities occurring in true and colloidal solution in such waters. Thus it had been established, within the limits of experimental error, that equal volumes of the same polluted water undergoing aerobic fermentation consumed equal quantities of oxygen, and gave rise to products which were constant in quantity, provided always that dissolved oxygen was present in excess. The rates of solution of oxygen and nitrogen by fresh and salt waters had been determined, and a well-defined mathematical equation obtained connecting rate of solution, surface exposed, volume of water, temperature and degree of saturation. Air dissolved by water at its surface did not remain concentrated in the surface liquid, but sank more or less rapidly, causing aeration to depths of at least 10ft., a process for which the term "streaming" was adopted by the authors. It was added that all the sewage of Sheffield is now being treated by the bio-aeration process, using mechanical agitators only, with most successful results, that method of the destruction of organic matter being essentially one of oxidation which, under aerobic conditions was effected by bacteria utilising the oxygen dissolved in the contaminated liquors.

Mr. John Haworth, M.B.E., the general manager of the sewage disposal department, Wincobank, Sheffield, contributed a paper in which he discussed the more modern methods of sewage purification and the steps by which they were developed, and described briefly a plant of the activated sludge type in operation at Sheffield, in which mechanical arrangements for agitation and mixing are adopted instead of compressed air.

In the early part of the paper he pointed out that if adequate areas of suitable land could be obtained and properly operated, the land treatment of sewage would still be an economic and effective method. Unfortunately, however, the necessary land of suitable quality was not available, especially in large urban districts. The inadequacy of most rivers or lakes to receive the large quantities of sewage concentrated at certain points rendered simple dilution methods also impossible.

The activated sludge, or bio-aeration process, of purifying the liquid portion of sewage with its colloidal suspensions marked a great step forward. The process was undoubtedly merely a step in the evolution of natural methods of sewage purification. The fundamental advance in the treatment of sewage by that method was the demonstration by Ardern and Lockett that if sewage were intimately mixed with well-oxidised bacterial humus in the presence of oxygen, the colloidal matters were deposited and, together with dissolved organic matter, were oxidised by bacterial action. The activated sludge method of sewage purification was, therefore, a purely natural process in which living organisms and their enzymes decomposed and oxidised the putrescible organic matters of sewage. The bacterial forms produced flocculent, gelatinous zoogleal masses in the sewage, which readily separated from the liquid and deposited as a sludge or mud. When that bacterial sludge was kept intimately mixed with sewage in the presence of free oxygen, organic compounds in solution and colloidal suspensions were absorbed or adsorbed on the zoogleal masses and were decomposed and finally oxidised. The sludge was readily separated from the purifying liquid by simple settlement, and was then suitable for application to further doses of sewage for a repetition of the action.

Among the advantages of the process over older methods of bacterial purification he mentioned that the provision of large masses of filtering media was rendered unnecessary, so that there was great economy in the area of land needed; the process could be operated without liability to nuisance from flies or objectionable odours, and the purification effected was equal to or greater than that effected by any other process and could be carried to any degree of efficiency required. The initial costs of installing plant operating the process were usually less than those for other types of plant; the operating costs were possibly slightly higher, by reason of the power costs involved, but as experience was being gained and apparatus improved, those costs were being reduced.

The essentials of the process were the necessity for keeping the required volume of active bacterial sludge intimately mixed with the sewage to be purified for the necessary period of several hours; the maintenance of free oxygen in solution as uniformly as possible throughout the mixture, and the prevention of any accumulations of settled sludge at any point in the system. In many plants those conditions were attained by admitting compressed air at the bottom of the tanks in a finely divided state, the air producing the necessary mechanical agitation of the mixture and also providing the oxygen to maintain the biological life. In other types of plant the agitation and mixing was obtained by means of mechanical arrangements, such as paddle wheels, centrifugal stirrers, surface brushes, &c. The author was led to adopt mechanical arrangements in preference to compressed air by reason of difficulties experienced in the choking of diffuser tiles and by the consideration that compressed air was not generally an efficient and economical mechanical device. During the last few weeks, however, there had been put into operation at Sheffield a new plant, having a new method of circulating the water round the channels and of obtaining the necessary aeration. The usual methods for preliminary treatment of the sewage were adopted, the sewage being passed through detritus tanks and screens, followed by Dortmund type settling tanks to remove the grosser solids. The settled sewage then passed to an aeration tank possessing novel features. Instead of paddle wheels, which had the effect of lifting the water in successive stages to create circulation, the floor of the channels was graded to such a fall that the lift desired to give the proper circulation was obtained in one stage by a suitable pump; a duplicate pump was provided as a standby. Each pump, which was of the axial-flow type, was rated to deliver 8600 gallons per minute against a static head of 4ft. 6in., and was direct-coupled to a 22 B.H.P. vertical motor working at 90 per cent. full load. The plant might be compared to an artificial turbulent river, about a mile in length, carrying the amount of bacterial sludge required to purify 500,000 gallons of sewage per day. The necessary aeration was obtained at the turbulent points in the stream.

The author mentioned also an interesting modification of the bio-aeration process which had been adopted at Birmingham. In that process sewage liquor was partially treated with activated sludge before application to percolating filters, thereby permitting much larger volumes of liquor to be applied to the filters than would be possible otherwise. In that case it was necessary to revivify or recondition the sludge after each operation by prolonged aeration in small bulk.

At Bradford, also, there was in progress an experiment in which the effluents from bacterial filters, produced from a strong trade sewage, were being impounded for a prolonged period in large lakes before discharge to the river. Already a remarkable flora and fauna was being developed in those lakes, with marked further purification of the effluents.

---

* See The Engineer, March 17th, 1933.

Finally, he asserted that bio-aeration methods of treating sewage had so far progressed that methods were available for purifying sewage to any degree required, without liability to nuisance, and at an economical cost. At the same time, the problem presented almost limitless fields for research in engineering, chemistry, and biology.

Mr. Frank C. Vokes followed with a paper entitled "The Treatment and Utilisation of Sludge," in which he dealt with the plant of the Birmingham Tame and and Rea District Drainage Board, which treats the sewage from a population of 1,200,000.

The process adopted, was, he said, to remove the sludge from the sewage as soon as possible and isolate it in separate digestion tanks. The operations were conducted in two stages. In the primary tanks the sludge was retained only so long as it was digesting vigorously and giving off gas. In the secondary tanks, the action was largely physical, taking the form of the extrusion of bound water. Inert sludge was then deposited and much of the separated water could be decanted off. The sludge was pumped on to drying beds, and some of it was sold to fertiliser manufacturers. Gas collectors were provided on the primary tanks and the gas was composed of approximately 60 per cent. methane, 29 per cent. CO_2, and 2 per cent. nitrogen. It had a gross calorific value of 685 B.Th.U. per cubic foot, and a generating station containing gas engine aggregating 950 B.H.P. utilised that gas for the generation of electricity, which was used for driving the plant at the Saltley works. The plant consumed about 56,000,000 cubic feet of gas per annum, and generated approximately 2,330,000 units of electricity.

At Yardley the Drainage Board had a works which received the sewage from a population of approximately 100,000, and the sludge digestion process had also been adopted there. In that case, owing to the small power requirements, the gas was mainly used for heating the sludge, and it had been found that the increased rate of digestion obtained by that means had allowed of a very considerable reduction in the capacity of the tanks, as compared with what would have been necessary had no heating plant been installed. The surplus gas was used to drive gas engines aggregating 46 B.H.P., which, as in the case of Saltley, generated electricity for works purposes.

It was claimed that the works of the Birmingham, Tame and Rea Board, where that process was in operation, had been working for a sufficient length of time to prove that by digesting the sludge, collecting the gas and utilising it for the generation of power, and for maintaining the sludge at a uniform temperature throughout the year, the modern sewage works could be independent of any outside source of power and was capable of providing the fuel for the whole of its own requirements.

The final contribution was by Mr. H. R. Lupton, who described in considerable detail machinery for dealing with sewage. This was intended rather as an appendix to the descriptions by other authors of the processes themselves, and was admittedly little more than a mere list of types of apparatus used for the purpose of treating sewage from the raw state. At the same time, attention was drawn to the principal points of interest in the various types of machinery described.

Mr. H. C. Whitehead (Engineer, Birmingham, Tame and Rea Drainage Board), said that in this country, at such centres as Sheffield, Birmingham, and the Potteries, purified sewage effluent was being used for trade purposes. He was not at all sure that we should not have to extend that practice further before long, and carry sewage purification to a degree at which the water could be safely used for trade purposes on a much larger scale. In the Ruhr sewage from a population of 1½ million people was mingled with the water supply to a population of 2½ millions, and four or five years ago he had been told that that water was used three times before it reached the Rhine. Londoners would apparently regard that as a state of affairs that could not be tolerated.

Mr. A. T. Gooseman (Leicester City Engineer) referred to experiments that had been carried out in Leicester to avoid the nuisance from screenings, both on the works and whilst being carted through the streets, the result being a process which he claimed to be a great advance upon disintegration. In that process—in which Leicester had been the pioneer—the screenings were discharged on to an endless belt and carried by a bucket elevator to a hopper and then discharged through a shoot into a digester. In that digester the screenings were cooked for from six to eight hours, the result being a valuable manure and the abatement of all nuisance. Originally it cost £300 per annum to dispose of the screenings, but after taking into account interest and depreciation on the plant a profit of £300 per annum was actually being made. The manure was fetching 5s. per ton, but the actual value was much higher, and he fully anticipated that when it was suitably advertised double that price would be obtained for it. He suggested the use of that system for seaside resorts as a means of eliminating the complaints so often made of the filthy state of the sea at the point of sewage discharge. Referring to the Leicester sewage works, Mr. Gooseman said they had cost £640,000, and pumped 36 billion gallons of sewage annually against a static head of 170ft. Some of the pumps, which were driven by steam, had been in use for forty years, and were still operating with every satisfaction. Others had been converted to electrical operation, but he did not care to risk the conversion of all the pumps, because he still regarded electricity supply as having elements of uncertainty, and could not afford to have those pumps inoperative for five minutes. He claimed that Leicester was getting results equal to any in the country and better than many.

Mr. F. R. O'Shaughnessy called attention to the changed mental attitude towards sewage purification in America in recent years, where they were actually reverting to mechanical filtration—giving up digestion—with incineration of the resultant sludge. He disagreed with certain statements made in the paper by Professor Adeney and Dr. Leonard. The suggestion that the humus in the separate digesting tank in the anærobic digestion process played a substantial part in preventing an offensive odour did not seem to him adequate, his own view being that the biochemical change brought about by anærobic digestion was entirely unconnected with the offensive odour which would be produced automatically if the material was left to itself. He also differed from those two authors in the view that ærobic digestion took place in two stages. In his view the whole process, from beginning to end, was a continuous one, and in the early stages there was a rapid elimination of non-nitrogenous material. Indeed, there was a good deal of evidence to show that in that process the nitrogen possibly played the part of a catalyst which took up oxygen and transferred it from the atmosphere and water to the non-nitrogenous material.

Professor F. G. Baily drew attention to the dirty condition of some rivers and lakes in Scotland, and said the trouble was that the Act of 1876 could only be put into operation, in fact, by those who were the chief sinners, viz., the local authorities, which were largely composed of the manufacturers who put dangerous trade wastes into the streams. The conditions in some cases were scandalous, and the streams were little better than open sewers. Whilst the position remained that local authorities had to put the Act in operation against themselves, there did not seem much hope of improvement.

Mr. F. T. K. Pentelow, of the Ministry of Agriculture and Fisheries, but who spoke in a private capacity, disagreed with the suggestion by Mr. Watson that there should be concentration of sewage disposal in large works, as compared with a considerable number of smaller works, in as much as the purity of river water depended on the relation of volume of sewage discharge and volume of river. If a number of towns of, say, 10,000 inhabitants, had their own sewage works, the discharge into the river would be comparatively small, and any deficiency in the purification plant could be made up for by the purifying action of the river. If, however, the sewage from a number of such towns was collected and dealt with at one works, and there was any deficiency in the sewage purification plant, the discharge of effluent would overtax the river at the point of discharge. That, at any rate, was a point to be borne in mind.

The President drew attention to the temperature of the exhaust gases of the engines using sewage gas, mentioned by Mr. Vokes, viz., 1130 deg., and contrasted that with the very much lower exhaust gas temperatures with gas engines generally and the figure in the B.S.I. specification of 370 deg., the object being to get as high a combustion efficiency as possible, and consequently a high efficiency.

The authors then briefly replied to the discussion.

Dr. Leonard said the matters to which Mr. O'Shaughnessy had taken exception in the paper by Professor Adeney and himself had been the subject of most careful experiment, and although in some respects the conclusions were a matter of speculation, the speculation was not unreasonable. In the same way it was difficult to contradict the suggestion that aerobic digestion was a one-stage and not a two-stage process, but the investigations that had been carried out were strongly in support of the view given in the paper.

Mr. Atter, commenting on what Professor Baily had said that in Scotland the County Councils had power to put the Act in force, said that the Lanarkshire and Midlothian County Councils had done that. Moreover, any person feeling aggrieved could complain to the Scottish equivalent of the Ministry of Health, which could take the matter up also. As to one large works *versus* a number of small works, the former policy had proved to be best in his own area, where there were 2000 miles of river, 2000 factories, and 400 sewage disposal works. In such circumstances the better scientific control possible in a large works had been found advantageous by comparison with the supervision, which was often left to a part-time road foreman or some such individual, of small works.

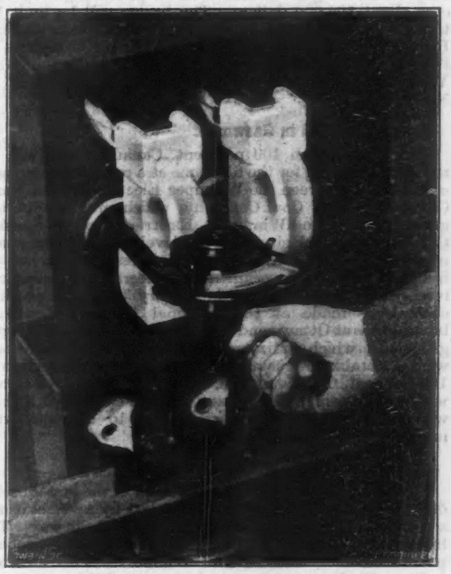
Mr. Haworth, speaking on the subject of re-used water, mentioned a case in which Parliament sanctioned a scheme by which 5 million gallons of purified sewage effluent were sent a distance of 11 miles for works purposes, thus releasing 5 million gallons of ordinary water for general use. The plant in that case was about to be put into use on account of the present dry spell. In 1929 it had also been used for a number of weeks, and by that means Sheffield had been able to spare one million gallons of ordinary water for a neighbour which was very short. The cost of the necessary plant was £450,000, and it was equivalent to installing a 5 million gallon reservoir at a very much higher cost.

Mr. Vokes, replying to the President, said the exhaust gases from the sewage gas engines was as high as stated in the paper, owing to the fact that methane gas was being burned, the speed of ignition of which was only one-tenth that of coal gas.

Mr. Watson, in a few final comments on the discussion, spoke of the progress being made in Japan, America, and Canada.

New "Tong Test" Ammeters.

Two new types of the "tong test" ammeter for measuring A.C. and D.C. without making an electrical connection have been introduced by Crompton Parkinson, Ltd., of Bush House, W.C.2. The special feature of both instruments lies in the design of the tongs, which are larger than usual. In the case of the type C instrument, shown in the accompanying illustration, the opening between the tongs is large enough to encircle porcelain fuse handles and cables up to 2½in. in diameter, and is particularly suitable for measuring current in the various circuits of unit feeder pillars. The other new instrument, designated type D, has tongs capable of embracing cables, bus-bars, or fuse carriers up to 3⅜in. diameter.



TONG TEST AMMETER

Like the original tong test ammeters, both of the new instruments are supplied with interchangeable movements, the standard ranges in the case of the instrument shown being up to 75, 100, 200, 300, and 400 ampères, and up to 100, 200, 300, and 400 ampères in the case of the D type instrument, the first scale marking in each case being one-tenth of the maximum reading. The total weight of each ammeter is 2¾ lb. If necessary, the new models can be supplied with ebonised tongs to enable them to be used on bare conductors run close together or in close proximity to earthed metal. A moulded bakelite handshield is fitted between the handle and the aluminium frame, so that when there is no risk of short circuiting adjacent conductors it is unnecessary to employ instruments with ebonised tongs. We are told that owing to error an electrician in New Zealand recently passed some 1500 ampères through a C type instrument, and although it was found impossible to open the tongs, when the instrument was subsequently tested, it was found to be absolutely accurate and undamaged.

A New Marine Oil Engine.

THE announcement is officially made that an agreement has been completed between Brooke Marine Motors, Ltd., of Adrian Works, Lowestoft, and the Associated Equipment Company, Ltd., of Southall, Middlesex, to manufacture at Brooke's Lowestoft factory a new high-speed marine oil engine for heavy fuel oil, which will be known as the Brooke-A.E.C. Diesel unit. The component parts of the new motor will be standard with those of the A.E.C. high-speed oil engine for transport vehicle work, but the design has been specially adapted to meet marine service requirements. The first of the new units, a 130 B.H.P. six-cylinder engine, is now under construction at Lowestoft. The cylinders have a bore of 115 mm. and a stroke of 142 mm., and full power is developed at a speed of 2000 r.p.m. The whole of the construction of the new engine will be carried out at Lowestoft. Primarily, the new engine will be distributed through the Brooke sales organisation, but jointly through the two firms. Messrs. Brooke will continue to supply their standard marine petrol engines and motor craft, and a full display of the firm's products, including, it is expected, the new engine, will be shown at the forthcoming Motor Exhibition, which will be held at Olympia from October 12th to 21st.

Canadian Engineering News.

(By our Canadian Correspondent.)

New Water Supply System.

For the water supply of the city of Niagara Falls, Ontario, a new intake is being constructed in the Welland River and a new 10,000,000-gallon filtration and pumping plant at Chippewa. The plant is laid out so that three additional units can be installed as needed, bringing the ultimate capacity to 40,000,000 gallons. Originally the city had an intake in the Niagara River just above the Falls, but the recession of the crest line made it necessary to abandon it some years ago. Since that time the city has been taking water from one of the conduits of a local power company.

Reservoir Completed.

The 30,000,000-gallon reservoir constructed by the city of Quebec on the Battlefields Park is now in full operation. Water was recently pumped into the second or eastern section of the dual containers for the purpose of flushing the big tank before finally filling it to its 15,000,000-gallon capacity. The western half of the reservoir was completed some time ago. This reservoir will supply water to the lower sections of the city on the north and south sides and will be a great benefit in the event of a serious fire outbreak.

Vehicular Bridge over the St. Lawrence.

Work has begun on the construction of a vehicular bridge across the St. Lawrence River. The project, which involves the planking of the New York Central Railway bridge from Cornwall, Ontario, to Nyando, New York, and the building of several miles of paved highway will cost about 300,000 dollars. The bridge will be built by the Cornwall and Northern New York International Bridge Company. The engineers and financial backers of the project are the George H. Flinn Corporation, of New York City, which built the famous Holland Tunnel at New York.

Canadian Coal in Gasworks.

Coke from 100 per cent. Canadian coal will be made in Winnipeg for the first time as a result of a contract entered into between the Winnipeg Electric Company and Crows Nest Pass Coal Company, which provides for the gasworks of the Winnipeg Electric Company using Canadian coal exclusively. This development is the result of several years of investigation and research carried on by the Federal Government engineers and industrial research staff. Extensive laboratory tests of Canadian coals were made at the National Research Council's laboratories at Ottawa and on a larger scale at the Winnipeg gas plant, which indicated that certain Canadian coals were adaptable for gas manufacture and the production of 100 per cent. Canadian coke, which would produce a coke with high heating qualities and low ash content at a price which will enable Winnipeg dealers to compete with imported coke.

First Transatlantic Steamer.

This year marks the centenary of the first crossing of the Atlantic Ocean from west to east by a vessel using, so it is stated by some authorities, steam all the way. The historic voyage was made by a Canadian-built wooden paddle steamer, the "Royal William." This steamer, built at Quebec, was launched in April, 1831, and towed to Montreal to be fitted with engines developing 200 horsepower. Her cost when ready for sea was 75,000 dollars. Her dimensions were :—Length overall, 176ft.; depth of hold, 18ft.; breadth over paddle-boxes, 44ft. She was originally intended to ply between Montreal and Nova Scotia, and the enterprise of building her was carried out by a group of Quebec and Halifax merchants, assisted by a grant of 15,000 dollars from the Government of Lower Canada. Among the shareholders appear the names of three Cunard brothers, one of whom later founded the present Cunard Line. After three moderately successful voyages in 1831 to Halifax and intermediate points she was laid up for the winter.

In the spring of 1833 a new company was formed, which purchased the vessel, and, for a time, used her for towing and local excursions. Then, in June, 1833, she sailed on a trip to Boston, where she was enthusiastically received as being the first steamship flying the Union Jack to enter a United States port. On her return to Quebec her owners decided to send her to England for sale. It was on this voyage that she made history, demonstrating to the world the feasibility of navigating the oceans by means of steam-propelled vessels, notwithstanding the declaration of critics that "they might as well talk of making a voyage from Quebec to the moon."

Early in August, 1833, she left Quebec for Pictou, in the Northumberland Strait, where she remained a few days coaling, storing, repairing engines, and awaiting passengers. Eventually, on August 17th, she steamed out of Pictou Harbour for England. Her clearance papers stated she was a vessel of 363 tons bound for London, that among the goods carried were 254 chaldrons of coal (324 tons), a consignment of ship's spars, a box of stuffed birds, one harp, one box, one trunk, household furniture and seven passengers, all British. Her master was John McDougall. During the voyage the starboard engine was disabled and the vessel sprang a leak. After twenty-five eventful days and nights the "Royal William" arrived at Gravesend. Ten days later the vessel was sold for 50,000 dollars and chartered to the Portuguese Government as a troopship.

In 1834 the ship was bought by the Spaniards, sent to Gravesend to be converted into a war steamer, and renamed the "Ysabel Segunda." Later she returned to the Spanish coast, and on May 5th, 1836, in the Bay of San Sebastian, she earned the distinction of being the first steamer of war to fire a hostile shot. In 1840 she was sent to Bordeaux for repairs, but was converted into a hulk. Her engines were transferred to a new ship of the same name, which ultimately sank off the Algerian coast during a violent storm in 1860. And so, with her hull rotting in Bordeaux Harbour and her engines lying at the bottom of the Mediterranean Sea, the "Royal William" ended her distinguished and varied career. A memorial tablet in the Canadian House of Commons commemorates the first Transatlantic voyage made by the "Royal William."

Shipbuilding and Marine Engineering.*

By A. C. HARDY, B.Sc.

This paper is mainly an extension of the ideas put forward in the author's paper of 1931 entitled "Marine Engineering as a Marketing Proposition," and deals with problems of marketing and distribution, and of salesmanship generally, with particular reference to existing conditions which are contrasted with the conditions existing in 1931, and with reference also to the problems to be faced by those firms which are coming fresh into the shipbuilding and marine engineering markets.

1933 and 1931 in Contrast.

The two years which have elapsed since the question of marine engineering and marketing was last touched on in an address before this Institute, have gone a long way to prove that by producing better and more economical "models," shipbuilders are forcing obsolescence on a great deal of existing tonnage. This, it was then suggested, would undoubtedly be the case. Unfortunately, the problem of disposing of surplus tonnage remains as prominent as it was then, although it should be remarked that there is a distinct tendency to regard with less sentiment than before the masses of old ships which continue to litter the world's harbours. If we can look to a future at all we shall find it increasingly obvious that rate of obsolescence of existing tonnage must be speeded up even more in the future. World shipbuilding may survive otherwise only as a series of government departments—into which, indeed, it may easily be in danger of transformation. The economy ships which have speeded up obsolescence have done so because of their low fuel consumption for an infinitely greater speed than was possible a few years ago, together with increase in the rapidity and efficiency with which cargo can be handled in ports. This has increased the competitive spirit among shipowners and has enlarged the field for auxiliary manufacturers. It will also result in the future in the world's goods being carried in a smaller number of faster vessels, steam or Diesel, of very high efficiency.

The number of ships per given route, therefore, must inevitably diminish in the future. Thus, world shipbuilding will decrease in quantity while increasing in quality. Assuming a return to "normal" economics of buying and selling which exists in practically no shipbuilding community to-day, returns will be better, but distribution different. A period of depression which, if existing work be a guarantee, is now slowly proceeding past its low point, has forced shipbuilders to develop economy models in order to attract shipowners so to arrange their finances that they can build them. In doing so, shipbuilders have, willy-nilly, limited quantitatively their potential output for the future. It is, therefore, only by producing more and more efficient models that they will continue to receive orders at anything like a rate consistent with their capacity. There is immediate consolation in the fact, however, that many large fleets must be reconstructed in the near future if they are to continue to give an efficient transportation service to clients. The example of the United Netherlands Company, which is gradually rebuilding the whole of its fleet, is worth remarking on. It is to be hoped that this will promote similar activities among other shipowners. For the shipbuilder, and with him the marine engineer, is faced with a battle in to-day's swirl of conflicting economic currents. He knows that the shipowner needs tonnage which, in some cases, controlling banking interests cannot, and in other cases lack of confidence in the future will not, permit him to order. The shipbuilder who is really alive knows that never before has he had more attractive propositions to offer. If he depends for his future upon the output of ships, is it not increasingly obvious that he must market his wares with greater persistency than ever before, appealing not merely to the owner, but to those people—often non-technical—who control the shipowner's policy, but who are capable of appreciating sound economics in the suggested financing of ships for entirely new trade routes ? These, as was pointed out in a previous paper, are even to-day possible, if a need for them is created.

The Shipbuilder's Point of View.

We can, with advantage, here enlarge upon the point of view of the shipbuilder. Lack of work to a shipyard means first, the discharge of skilled workmen, then, as matters get worse, the technical staffs who are behind the skilled workmen must suffer salary reductions, and later dismissal. This means that the trained staffs upon whose skill the successful production of the ship itself depends are gradually dispersed, a situation equivalent in fact to the dispersal of a well-trained football team, for the shipyard itself depends for its fine productions upon the team work of its design and drawing offices and its managerial staff. This, in general, is the position to-day in those countries whose shipyards are not given artificial life by means of Government or other subsidies. Even those yards, sooner or later, may suffer far more severely than non-subsidised yards from that species of collapse which is said to be the final condition of a patient whose strength has been maintained by drugs or some other artificial method, unless State control of industry prevails throughout the world, and if shipbuilding is to survive under normal economic conditions.

With such gloomy sentiments prevailing, surely it must seem that shipbuiders who have no hope for the future should cut their losses and close their yards; but on more mature examination it is clear that such a course would be as ridiculous as it would be unwarranted. Shipbuilding, in common with other industries, is undergoing a purifying process, and post-slump shipbuilding will bear no recognisable relationship to pre-slump shipbuilding. Not only will the post-slump shipyards be infinitely fewer, but they will be infinitely keener. They will be a virile fighting force, and they will not be controlled by boards whose feeling with regard to clients is that they (the clients) should come to the shipbuilder and ask him to build them a ship. The difference between the salesman of new ships and the salesman of life assurance policies, or of advertising space, will be merely that inherent in the commodities which each one is handling. Their vigour, persuasiveness and energy must be identical.

Postulating a slow world recovery possibly to an entirely different set of trade conditions, this recovery may be even more the age of the salesman than has been the case in the past. By that time hard economics will necessitate that boards of directors be composed of keen, hard-headed men of business whose trump cards are their international outlook, their flexibility and their ability to be in any port of the world as soon as a new contract is mooted. Such characteritics will, however, only be possible in those shipyards which have survived the slump. But the shipyards which survive, and the process of attrition is by no means terminated in this country, must be capable of tackling on an international basis contracts for all types of ships and at competitive prices. Furthermore, they must maintain a strictly impartial attitude on the ship powering question.

Contracts in future will be confined even less than hitherto to the shipyards of the country to which the owner happens to belong, and this in spite of a prevailing spirit of nationalism which bids fair to bind the wheels of commerce—a spirit which can only be kept alive by State assistance of a peculiarly blind nature. There is every indication that they will be placed on an international basis. Already, for example, there are signs that Holland is actively allying herself with Scandinavia in this connection. Such being the case, the shipbuilder of the future will have to maintain international connections. Fortunately, signs are not wanting that those British shipyards, which have all the appearances of being able to hold on until after the slump, are doing this. There is a yard on the Tyne with excellent Canadian, French, and Scandinavian connections. There is a yard on the Clyde which has built simultaneously for South Africa, for India, and for Wallasey. The shipyards of Belfast have built for Dutch, for French, for British, and for American owners. No shipyard can prosper, however, unless it keeps rigidly abreast of modern requirements. For this reason the action of British yards is to be deplored who, in search for best economy with coal fired steam plants peculiarly their own, have gone to the leading Scandinavian motor ship building yards to supply it. This is a grave indictment upon the efficiency and ability of British marine steam engineers.

The Ship of the Future.

It is interesting to speculate as to what the ship of the future may be like. In all probability the mean speed of ships will be higher. The pre slump idea was that if a cargo vessel of tramp type could make approximately 10 knots on a very high coal consumption, she was a perfectly efficient trading weapon. This is no longer true, and the higher mean speed of 12½ knots which such ships can make is partly due to the fact that extra speed can be obtained on a relatively much lower fuel consumption. The internal combustion engine, together with improvements in hull design, have made this possible, and the re-designing of the sterns of ships of single-screw type has also been of assistance, while changes in propeller design and in the outline of rudders have also been responsible for certain developments ir this connection. The internal combustion engine, using, as it does, approximately one-quarter of the amount of fuel that the old-time steam plant does, and with its ability to give increased speed with very little increased fuel consumption, has naturally recommended itself to a large number of shipowners, and in particular to Scandinavian shipowners. Apart from large passenger liner and cargo liner contracts which may be given out in the next few years, a large number of the tramp contracts are likely to be financed in connection with Scandinavian owners who are very expert in the operation and "management" of ships and who regard the map of the world not only as something which has routes emanating from British coal ports to grain ports and back. They are looking at the whole question from the point of view of countries which are likely in future to have large exports, and here the Pacific Coast of North America undoubtedly holds out a very bright future. The tramp of the future, in fact, may well be a fairly high-speed motor vessel, built and planned internationally, with a speed of 12 knots or over, and of a size and type which in pre-slump days would have been dignified by the name of a cargo liner. She may even have refrigerated space and accommodaton for the carriage of vegetable oils, and she will most certainly operate in the trans-Pacific trade if necessary. So, too, with the cargo liner in which ship type, if present trends are to be judged, speeds of anything up to 18 knots in loaded condition may be expected within the next few years.

Electricity and Auxiliaries.

Thus the shipbuilder and the marine engineer must inevitably work hand in hand. The outlook for the auxiliary maker is a much brighter one and particularly if his work is connected with electrification. Many ships to-day are electrically propelled. Others are 80 per cent. electric in the sense that all their auxiliary equipment is electrically operated. The electric ship, and, in particular, the turbo-electric ship, has introduced a new technique into the business of marine engineering, and in some cases the part played by the marine engineer is a small one. The boilers are built in one part of the country, the turbines may be built in another part, and the electrical equipment in yet a third, the two latter being under the control of one concern. As regards auxiliary gear, the winches are the work of specialist firms which have been connected with the construction of steam winches. The pumps, &c., in the power room, as well as the ventilation and forced draught fans, are electrically operated, and even though pumps and fans may be made by further sub-contractors, the motors operating them come under the constructional control of the makers of the main turbo-electric propelling machinery. Thus, a contract for a complete turbo-electric ship is a very valuable thing for an electrical manufacturing company to-day. Important auxiliaries, such as fan and pump motors, winches, control gear, &c., are in the hands of specialist firms with moderate sized organisations and reasonably low overheads. They have established names for themselves for the supply and installation of this equipment, not only in this country, but abroad. They have the entire confidence of the marine fraternity, as is instanced by the fact that whilst the whole of the electrical equipment of a recent large turbo electric liner was supplied by a leading electrical manufacturing concern in this country, certain parts of the installation were carried out by a smaller firm which has built up a reputation in the last few years for all kinds of auxiliary work.

---

* Institute of Marine Engineers, September 12th.

Further development, it may be suggested, will lie in giving to the question of electric propulsion and electric ship equipment rather a new "slant." There should be, for example, in Great Britain, a future for such arrangements as dead front switchboards and for their logical placing in the ship, *i.e.*, at control platform level, and not on some almost inaccessible platform at the back of the auxiliary engine-room. Such developments, in addition to straight turbo or Diesel-electric propulsion in certain countries, also form a valuable export market. Great Britain's success during the Victorian era lay partly in the fact that she was always ahead of technical progress. To a certain extent we have "missed the boat" as far as the Diesel engine is concerned, with the brilliant exception of the activities of one or two companies in this country, and this fact is, in part, responsible for our present position in world shipbuilding; but there is no reason why we should miss the electric ship in a similar way.

Although the electrically propelled ship originated in the United States, it has now come to Europe, and on the turbo-electric side Great Britain has done more than any other country to develop it. On the Diesel-electric side, whilst France has tended to push ahead rather further than our own engineers to date, there is every indication that there will shortly be a reversal of this trend, and that Diesel electric propulsion will be adopted in a large number of ship types in this country. Already a valuable start has been made in connection with tugs and ferry boats, whilst it is certain that other vessels will be built with this type of propulsion in the near future. Is there any reason why the electric ship for those purposes for which it is suited should not become an export of British shipyards and British marine electrical concerns? Much depends on the way in which the idea is "sold," and although it would probably be absurd to suggest that complete Diesel electric tugs could be sold to Continental countries, there is no reason why electrical and Diesel equipment should not. In this connection we can cite the cases of a Diesel electric tug for the port of Antwerp and a Canadian Lake ship, in each of which the electrical gear was supplied by British firms. Apart from this, there is a large potential market overseas in the Dominions, Crown Colonies, &c.; as an example, the complete Diesel electric equipment for a new Hong Kong ferry has been fitted in a vessel in China.

There is a danger which should be pointed out here, but it is one which can be easily overcome. Where the hull is being built on one side of the world, and the propelling machinery on the other, complete liaison should be maintained between the builder and the machinery constructor to ensure that exactly the right propeller and machinery revolutions are arranged, and, above all, with high speed Diesels, that due attention is paid to seating design. Any design which the shipyard puts out in this connection should be rigorously overhauled by a competent naval architect on the staff of the machinery builders before scantlings, &c., are agreed to. Incidentally, a double liaison is required. When the electrical equipment is being built by one firm and the Diesel engines by another, and the hull by a third, the electrical manufacturer must deal with the Diesel manufacturer, and both, in turn, must deal with the hull builder. If the closest co-operation is not secured, failure may result, and the course of Diesel electric development be diverted for a number of years.

THE COMPLETE "DIESEL ELECTRICIAN."

If the firm constructing the electrical machinery were also to build their own Diesel engine, not only would all-through liaison be possible, but the electrical man would have a much better idea of the capabilities of his engine. Likewise, because all the machinery came from one organisation, the overall cost must be lower, and that is going to be one of the chief selling points as far as Diesel electric propulsion is concerned in the future. Such an arrangement would operate for the majority of orders for which quotations were invited, provided the range of Diesel engines was sufficiently flexible, not only as regards powers, but also speed and size. With the spread of Diesel electrification into an increasing number of special craft, however, particular kinds of Diesel engines would often be required, and the firm would, therefore, be called upon from time to time to go outside the range of its own engines, but they must be careful in their choice. In the past there has been far too much inclination on the part of electrical manufacturers to choose their engines carelessly. Whichever way we look at the matter, the electrical ship is bound to be the ship of the future, not necessarily with electrical propulsion, although the future here is good for certain specific types, but particularly for auxiliary equipment. To descend from the general to the particular, we may consider even such a matter as electrical steering. The shipping world must shortly adopt a really satisfactory all electrical gear, because, *inter alia*, this is more compact than an electric hydraulic gear. Many such arrangements do exist and operate with complete success, but in this country the tendency, at any rate, merely because there is not sufficient confidence, is towards the electric hydraulic gear. Then, too, there is the question of electric deck cranes, which deserves close attention. Germany and Denmark both have satisfactory types which can handle cargo effectively from the water alongside, but so far there is no British model. A special plea must be made for this, because it is a saleable article, and because it must in the future considerably augment the work of winches.

These, then, in brief, are some trends of the situation as it exists at present. It may be said in criticism of the review that few, if any, definite conclusions have been arrived at, a criticism which may be answered by saying that to day it is impossible to foretell accurately where economics may take us, and how world events may alter with natural laws. Post slump shipbuilding and marine engineering, purified and shrunken by the elimination of the weaker members, does not present a hopeless picture, but initiative on the builders' part must be one of the foremost characteristics among those who remain. Whatever be the ultimate economic trend, it would appear that some form of "salesmanship," if we interpret the term in its widest sense as liaison between builder and owner, will be necessary. For the rest we may say that if our industries are to survive as separate self-supporting units, production must be studied and controlled, and scientific marketing must be part of their programme. The continued production of more and more efficient "models" would appear to be the keystone for the development of new construction other than that of a purely replacement nature.

The Electro-Chemical Theory of Corrosion.[*]

By OLIVER P. WATTS.[†]

IT has been said of electrolysis that it splits a chemical reaction in two and permits the halves of the reaction to occur at different places. The beauty of this characterisation can be appreciated only by those who are conversant with both electrolysis and corrosion. In ordinary cases of corrosion, such as the attack of zinc or iron by sulphuric acid, the two halves of an electrolytic reaction have been put together again, and the same piece of metal serves as anode and as cathode. The most fundamental law of electrolysis still applies, viz., Faraday's law, that the total of chemical changes at the anode, where metal tends to enter solution, equals the total changes at the cathode, where elements leave the solution. The amount of hydrogen displaced from sulphuric acid by zinc is equivalent to the quantity of metal dissolved. This seems to indicate that the nature of the processes by which metal passes into solution by chemical and by electrolytic corrosion is the same.

According to the old view, attack on a metal like iron by an acid such as hydrochloric is strictly a chemical process, the greater affinity of the iron for chlorine enabling this metal to rob the acid of its chlorine, thus displacing the hydrogen.

To-day the majority of students of corrosion, and probably of chemistry also, appear to have accepted Nernst's view, that the dissolving of metals by acids or other corroding media takes place by ions (electrically charged atoms) leaving the surface of the metal. All that is needed for atoms of a metal to go into solution is that they be provided with tickets of admission, a number of positive charges equal to the valence of the metal in that particular solution. The former importance of the anion has vanished. Now it serves only for carrying current through the solution, and of itself contributes in no way to the dissolving of metal. The army of anions on reaching a soluble anode merely come to rest there and permit the metallic ions leaving the anode to pass peaceably through their ranks.

CORROSION CLASSIFIED.

Except for a single type, not often encountered, all corrosion of metals is by displacement. For simplicity and convenience, corrosion may be classified as follows:—

(1) *Corrosion without displacement of anything from the corroding solution, e.g.*, the dissolving of iron or copper by a solution of ferric chloride.

II. *Corrosion by displacement of a metal, e.g.*, the dissolving of iron by a solution of copper sulphate or of zinc in the recovery of gold from cyanide solutions.

III. *Corrosion by visible displacement of hydrogen, e.g.*, the dissolving of zinc by sulphuric acid.

IV. *Corrosion by invisible displacement of hydrogen*, following by its physical or chemical removal, *e.g.*, the corrosion of iron by sea water or of copper by dilute sulphuric acid. This is often called corrosion by oxygen depolarisation.

Type I.—This kind of corrosion occurs only when there is in the corroding solution in one of its higher valences a metal which is capable of existing in solution in at least two valences. Corrosion of this type is seldom met commercially, but is made use of in etching metallographic specimens with ferric chloride. Metal dissolves with equivalent lowering of the valence of the metal previously in the solution.

Type II.—In arranging electro-chemical series of the metals, this type of corrosion was extensively studied in the early part of the nineteenth century, although attention was then focussed on the deposition of the one, rather than on the corrosion of the other of the two metals concerned in each case. The serious consequences of confining in a tank or pipe made of an active metal a solution containing a much more inert metal, is so well known that this type of corrosion is rarely encountered. One metal replaces the other in solution. Short of actual trial, tables of potentials and of solubilities furnish the best basis for prediction in regard to this type of corrosion.

Type III.—Corrosion by visible displacement of hydrogen is possible only in those electrolytes from which the electric current deposits hydrogen, *i.e.*, water, and solutions of acids, alkalies and salts of sodium, potassium, aluminium, &c. Visible displacement of hydrogen occurs when the potential of the metal exceeds the discharge potential of hydrogen on that metal from that particular solution.

Type IV.—Corrosion by invisible displacement of hydrogen is by far the most common type of corrosion, yet is least understood. This occurs only with those metals and in those solutions in which the discharge potential of hydrogen exceeds the potential of the metal. Corrosion by invisible displacement of hydrogen proceeds as follows: When the metal is immersed in the solution it begins to dissolve, displacing its equivalent in hydrogen. This continues until the counter e.m.f. set up by hydrogen equals the thrust of the metal to go into solution, when dissolving of metal and displacement of hydrogen cease. In the case of metals whose potentials lie far below the discharge potential of hydrogen on them, the contact surfaces of metal and electrolyte must be far from saturated with hydrogen.

Oxygen from the air dissolved in the electrolyte removes hydrogen by formation of water, thus lessening the force with prevented further displacement of hydrogen, so that dissolving of metal begins again. The speed of solution of metal is limited to the rate at which oxygen reaches its surface.

PURITY *versus* CORROSION.

Will a perfectly pure metal corrode? This question has often been argued *pro* and *con*, usually with the result of leaving each of the disputants "of the same opinion still." Several authorities on corrosion disagree on this seemingly simple question, which, nevertheless, involves the fundamental principles of corrosion.

The whole argument for cessation of the corrosion of metals, if they could be obtained perfectly pure, is based on the stopping of visible displacement of hydrogen by amalgamated zinc and by certain samples of this metal of exceptional purity. No thought seems to have been given to the fact that corrosion by oxygen depolarisation still goes on—that variety of corrosion which is responsible for the major part of the annual damage by corrosion.

Advocates of the necessity for voltaic couples, points of different potential, as an antecedent to corrosion, apparently limit this claim to cases where anode and cathode consist of the same piece of metal. No one has yet claimed that there must be impurities in a metallic cathode in order that hydrogen may be displaced on it by electrolysis.

Should further experiments prove definitely that no perfectly pure metal is capable of visibly displacing hydrogen on itself from acids, which seems utterly incredible in the case of sodium, potassium, calcium, &c., nitric acid would still continue to dissolve absolutely pure zinc and copper, and corrosion of these metals in sulphuric acid by oxygen depolarisation would go on, as would corrosion by displacement of other metals and by the method of Type I. of the author's classification. Metallurgists need not worry about zinc being made so pure that it will fail to precipitate gold from cyanide solution and sacrifice itself in doing so.

THE ROLE OF OXYGEN AND OXIDISING AGENTS IN CORROSION.

It is observed that oxygen and oxidising agents stimulate corrosion of metals. Early in the history of the voltaic cell it was discovered that unless an oxidising agent was placed at the cathode, the current delivered by the cell quickly diminished through polarisation by hydrogen—*i.e.*, deposition of hydrogen on the cathode caused its potential to approach that of the zinc, thus lowering the e.m.f. of the cell. With few exceptions, the electrolytes of voltaic cells are those from which hydrogen is deposited at metallic cathodes when electrolysis occurs. To prevent this serious fall in e.m.f. during use, oxidising agents are placed at the cathode either as a constituent of electrode or electrolyte. Studies of the Leclanché cell have shown that reduction of the manganese dioxide accounts for removal of only half the hydrogen deposited at the cathode. The remainder is removed by oxygen from the air dissolved in the electrolyte. In Vol. 62 of the "Transactions" of this Society a commercial air-depolarised cell is described. Polarisation at the cathodes of primary cells has long been known, understood, and the removal of the polarising hydrogen provided for by oxidising agents, and finally by atmospheric oxygen.

About eighty years' study and experimenting in corrosion was required before this was recognised as electrochemical in character, and the function of oxygen in stimulating corrosion was not made clear for several years more. In any aqueous solution from which hydrogen is deposited on metallic cathodes, its deposition tends to displace the potential of the metal toward that of zinc. It is not necessary that there be enough hydrogen on the metal for visibility in order to cause this change in potential. It begins as soon as any e.m.f. is applied to the cell, and if the e.m.f. is gradually increased it continues until both electrode and electrolyte at the metal-electrolyte interface are saturated with hydrogen and the gas begins to escape.

When a metal is placed in a solution of sulphuric acid or sodium chloride, it begins to dissolve by the only process possible, by displacing some other element from the solution. In acids and solutions of sodium and potassium salts the substance displaced is hydrogen, the element which is deposited at cathodes from these solutions by electrolysis. In a voltaic cell without a depolariser, *e.g.*, amalgamated zinc-sulphuric acid-copper, hydrogen is visibly evolved from the copper, and no one can doubt its displacement by the dissolving of the zinc. When copper is placed in dilute sulphuric acid, it, too, starts to dissolve by displacing hydrogen, but the discharge potential of hydrogen on copper from dilute sulphuric acid exceeds the potential of copper in the same electrolyte; hence copper can continue dissolving only until hydrogen has accumulated on the metal to a concentration equivalent to the potential of copper; then there is equilibrium, and no more copper can dissolve until some of the hydrogen is removed, thereby lowering the opposition to its deposition. If air has access to the electrolyte, the oxygen slowly removes hydrogen and permits copper to dissolve at the exact rate necessary to replace the hydrogen as fast as it is removed. In the complete absence of oxygen copper does not corrode perceptibly in dilute sulphuric acid in years.

In April, 1926, the writer sealed in glass tubes in normal sulphuric acid inch-long (2·54 cm.) pieces of bright copper wire. The acid was boiled in the tube under diminished pressure and sealed under vacuum. One tube was left unsealed. The wire and liquid in this have completely disappeared, and in their place is dry copper sulphate. The acid in one tube became faintly blue after a month. Careful scrutiny showed a minute crack in the glass where sealed. Although the liquid has not evaporated enough air has diffused through the crack to cause serious corrosion of the copper. In two other tubes the acid is still water-white, and the copper is as polished as when put into the tube seven years ago.

Not only does a zinc anode displace hydrogen on the cathode of a voltaic cell when they are connected, but it displaces hydrogen on itself. In neutral electrolytes, from which the discharge potential of hydrogen on zinc and its impurities exceeds the potential of that metal, no hydrogen is seen; but in acids where the discharge potential of hydrogen is much lower, it is necessary to amalgamate the zinc to prevent continuous evolution of hydrogen on the anode and corresponding waste of zinc. Although there is now no evolution of hydrogen on open circuit, corrosion by oxygen depolarisation goes on. This corrosion of amalgamated zinc by depolarisation of the invisible film of hydrogen always present on it was recognised years ago, and the zincs were removed from the single-fluid bichromate cell when not in use, to prevent waste through oxidation of the hydrogen film by the chromic acid.

---

Corrosion by Differential Aeration.

Corrosion by differential aeration has been much discussed. When two separate pieces of iron are placed in a neutral electrolyte and oxygen maintained at a higher concentration at one piece than at the other, the iron with the higher oxygen concentration corrodes faster and its potential is lower (more noble) than that of the other piece. When the electrodes are connected, each piece is privileged to displace hydrogen on the other as well as on itself. Enough current now flows from the metal where hydrogen is the more concentrated to raise the polarisation by hydrogen of the other electrode until their potentials are equal, except for the e.m.f. required to drive the current through the cell. The corrosion of the two electrodes should differ by an amount equivalent to the current.

Two explanations are suggested for corrosion by differential aeration. The first is that an oxide film is formed on the metal having the higher concentration of oxygen. "It is clear, therefore, that the formation of protective films on the aerated part of the metal does play a very considerable part in causing the aerated area to be cathodic."‡

"The portions to which oxygen has least ready access are those where corrosion is greatest. This conclusion may at first sight seem almost paradoxical, but the action of oxygen is of the direct chemical type, giving at the aerated portions a uniform film having some protective qualities. These parts are thus ennobled and the parts sheltered from oxygen are relatively electro-negative (more active) and dissolve by anodic attack of the ions in solution."§

The other explanation is that this is merely a case of ordinary corrosion by oxygen depolarisation, except that the two portions of the same metal which act as anode and cathode happen to be connected by wires instead of being a single piece of metal. The initial differences in potential are characteristic of metals when the hydrogen concentration at the metal-electrolyte surface is changed.

It is generally considered that the velocity of corrosion by oxygen depolarisation is controlled by the rate of diffusion of dissolved oxygen to the metal. This means that when the oxygen arrives at the metal surface hydrogen is already there, and the oxygen has a choice of uniting with hydrogen or metal. That an oxide should be formed in the presence of hydrogen, and later be reduced by hydrogen, seems an entirely unjustifiable, not to say unreasonable, assumption. Granting that an oxide is formed, it should, like the copper oxide cathode of the Edison primary cell, prevent accumulation of hydrogen, and so promote continued flow of current. Dr. Blum makes the revolutionary suggestion that no hydrogen is displaced by metals dissolving by oxygen depolarisation, but that "cathodic reduction of oxygen can be considered an electron reaction, which is much more likely to occur than the frequently assumed process of hydrogen evolution and subsequent reduction of oxygen by hydrogen."

Electrolytic Protection.

In electrolytic protection the metal is made cathode and loaded up with hydrogen by an external e.m.f., so that there shall be no point on which the metal can itself push out hydrogen. In the Gunderson process plating with arsenic insures that there shall be no corrosion of the steel by visible displacement of hydrogen, for the discharge potential of hydrogen on arsenic, even from acids, exceeds the potential of iron.

Residual Current and Corrosion.

Residual current is that microscopic current which flows in an electrolytic cell at any voltage below the e.m.f. of decomposition without visible products of electrolysis. It is the current equivalent of the rate of depolarisation of the electrodes by the electrolyte. At a constant voltage the current diminishes with time, but never ceases. It has been studied both with platinum electrodes and an e.m.f. external to the cell, and with electrodes of different metals, in which case the cell supplies its own e.m.f.

Corrosion of type IV. is the same phenomenon, except that here a single piece of metal serves both as anode and cathode; but the corrosion is controlled by the rate of removal of hydrogen by dissolved oxygen, just as both current and corrosion in the experiment cited are fixed by the rate of depolarisation of the cathode. A thorough study of residual currents under various conditions should throw much light on corrosion of type IV.

A Film of Hydrogen.

Metals, when placed in acids or solutions of sodium salts, must displace on themselves a concentration of hydrogen equal to their own potentials, else there would be no acceleration of corrosion by oxygen depolarisation. Copper, silver and other inert metals which are incapable of visibly displacing hydrogen from dilute sulphuric acid, corrode very slowly when allowed to stand in the acid.

It is only at the potential of copper in sulphuric acid, for example, that there can be equilibrium between copper and hydrogen; at any potential more noble than this, if copper began to deposit on a cathode, it must re-dissolve with displacement of hydrogen until equilibrium is reached. So very minute currents of the order of magnitude of residual currents deposit hydrogen, not copper, from air-saturated solutions of copper sulphate.

In the early days of the study of corrosion the mistake was made of attributing the stopping of corrosion by the film of hydrogen to its insulating power, and in some quarters this erroneous opinion is still held. It is the polarisation (counter e.m.f.) produced by it, not its resistance, that reduces corrosion and the current in voltaic cells. In one case the residual current between nickel and iron was found to be 1/20,000 of the current density usually used in chromium plating, where a storm of hydrogen is evolved at 6 to 8 volts. The resistance of the films of hydrogen encountered in corrosion are negligible.

Nernst's Osmotic Pressure and Helmholtz's Electrolytic Double Layer.

"According to the well-known classical theory of Nernst, each metal has a definite solution pressure, which is a measure of the tendency of the metal to pass into aqueous solution in the form of ions. This solution pressure is opposed by the osmotic pressure of the metal ions, which tends to drive them out of solution, depositing them on the metal. With the reactive metals, such as zinc, the solution pressure is greater than the osmotic pressure, positively charged zinc ions go into solution, and the metal acquires a negative charge. When the solution pressure is less than the osmotic pressure, as in the case of copper and the 'nobler' metals in solutions of their salts, ions of the metal are deposited, giving a positive charge to the electrode, whilst the solution in the vicinity is negatively charged by the corresponding anions. The surface of the electrode is thus the seat of an electric double layer."[3]

The solution pressure of zinc is stated to be $9{\cdot}9 \times 10^{18}$ atmospheres, or five million billion tons per square inch, and that of copper $4{\cdot}8 \times 10^{-20}$, a quantity unimaginably small.

"In accordance with Nernst's assumption, when a bar of zinc is placed in water, zinc atoms each give up two electrons to the bar of metal and pass into the water as positively charged ions. In this way an electric double layer is formed at the junction of the metal and liquid. That but an exceedingly minute quantity of zinc enters the water in the form of ions, notwithstanding its enormous electrolytic solution pressure, is due to the electrostatic attraction of the negative charges which accumulate on the bar of metal. Evidently the relative values of the osmotic pressure and the electrolytic pressure determines whether ions leave or enter solution."[4]

Helmholtz's double layer is a myth. Not only is it stated above that metal ions pass into solution without displacing their equivalent in other positively charged ions, but the very existence of a double layer depends on their doing so. If metals dissolve by displacing on themselves, or another conductor in electrical contact with them, their equivalent in positively charged ions, there can be no accumulation of electric charges on either metal or electrolyte! Experience shows that, except for type I., all corrosion of metals is by displacement.

Nernst's conception of the "osmotic pressure" of the ions of the metal already in solution as equalising or even overcoming solution pressure, chemical affinity, or whatever name is applied to the force which causes metals to dissolve, is also untrue. A sheet of copper, 48 square cm. in area, immersed for twelve days in 250 cc. of normal copper sulphate lost 0·1386 g. in weight! According to Nernst, as quoted above, copper tends to deposit from solutions of its salts.

How can osmotic pressure and an electrolytic double layer be reconciled with this corrosion of copper in a strong solution of copper sulphate by oxygen depolarisation? Yet modern texts on physical and electrochemistry continue to present Nernst's theory of osmotic pressure and Helmholtz's double layer as "law and gospel," to be swallowed by embryo scientists, greatly to the impairment of their scientific digestions! These figments of the imagination were created to explain the practical stopping of corrosion of the anode in certain primary cells when the circuit is opened, and the fact that metals of high potential fail to dissolve quickly and completely when placed in neutral electrolytes. Now that it is known that their supposed job of limiting corrosion is performed by hydrogen, and that they were never capable of doing it in the first place, they should be plainly labelled as scientific conceptions that have outlived their usefulness.

After thirty years, Whitney's statement that corrosion is electro-chemical in nature still stands as our best definition of the electro-chemical theory of corrosion.

BRITISH STANDARDS INSTITUTION.

All British Standard Specifications can be obtained from the Publications Department of the Institution at 28, Victoria-street, London, S.W.1. The price of each specification is 2s. 2d. post free, unless otherwise stated.

GRAPHICAL SYMBOLS.

No. 108—1933. A British Standard List of Graphical Symbols for Electrical Purposes was issued in 1922, and at about the same time the International Electrotechnical Commission started to interest itself in the question of symbols. The British National Committee (*i.e.*, the Electrical Industry Committee of the British Standards Institution) participated in this international undertaking, and in the course of the preparatory work, a number of suggestions were noted for consideration when the B.S. Symbols came up for revision. The International Electrotechnical Commission published its report on Symbols in 1930, and the revision of the B.S. Symbols was then considered in detail, with the result that B.S. No. 108—1933 has just been issued. The revision of the previous edition has been thorough, and although no changes have been made merely for the sake of a change, the internationally agreed symbols have been substituted in a large number of cases. In other cases the international symbols are in conformity with current British practice so that no change has been necessary.

The new list of symbols is fuller than the old list, but a note in the Introduction makes it clear that still further additions will, no doubt, be called for as the applications of electricity develop.

An important new feature is the introduction of a letter code, the object of which is to reduce the number of graphical symbols that would otherwise be necessary. The code letters, which are devised on a mnemonic basis, are, in certain cases, embodied in the graphical symbol itself, but in the majority of cases they are intended to be written alongside the graphical symbol. In either position, however, the code letters provide a ready means whereby a tabulated index of symbols used on any diagram may be indicated on each drawing. A comprehensive wiring diagram, embodying as many as possible of the graphical symbols, is included in B.S. 108—1933, as an example of the application of the letter code.

BRITISH STANDARD CAST IRON MANHOLE COVERS AND FRAMES.

No. 497—1933. The British Standard Specification for Cast Iron Light Manhole Covers and Frames, No. 497, has recently been issued by the British Standards Institution. The covers and frames dealt with are intended for domestic purposes and not designed to carry traffic loads. A specification for heavier covers for this purpose is being contemplated. The present specification deals with quality of material, dimensions, weights, galvanising coating, soundness and inspection by the purchaser. The standard sizes provide for interchangeability and replacement of broken covers without the trouble and expense of removing existing frames.

ROAD MOTORS FOR THE L.M.S.

The L.M.S. Railway Company announces that orders have been placed with British motor manufacturers for 166 new road motor vehicles and for the reconditioning of twenty-five chassis. These orders, which comprise the company's programme of new road motor vehicles for the current year, embrace all types of motor vehicles, including heavy lorry chassis, liverstock carriers, light parcel vans and "mechanical horse" tractors. An important feature is the placing of orders for a further seven vehicles of a special type for augmenting the services recently inaugurated by the L.M.S. in agricultural areas for the transport of livestock.

Details of the various orders are as follows:—

Albion Motors, Ltd.—Nine LK 50 5-ton chassis, with Gardner 4 L.W. engines; one LJ 27 4-ton petrol engine chassis; five LC 43 2-ton petrol engine chassis. These vehicles will be fitted with cabs and bodies in the L.M.S. carriage and wagon department works.

Leyland Motors, Ltd.—Five Leyland Beaver 6-ton chassis with Leyland compression ignition engines, forward control type with cabs. Bodies to be fitted in L.M.S. works.

Karrier Motors, Ltd.—Six CY 3 2-ton chassis to be fitted with parcels van bodies in L.M.S. works

Associated Equipment Company, Ltd—Six Mercury 4-ton chassis, with compression ignition engines; cabs and bodies to be fitted in L.M.S. works; Seventeen A.E.C. Y type chassis to be reconditioned and fitted with Gardner 4 L.W. engines, C.A.V. lighting sets and pneumatic tires; cabs and bodies being fitted in L.M.S. works.

Ford Motor Company.—Twelve Fordson BB 2-ton chassis, 157in. wheelbase, bodies fitted in L.M.S. works; thirty Fordson BB 2-ton chassis, 131½in. wheelbase, bodies fitted in L.M.S. works; four Ford 1-ton chassis; one Fordson hand-operated tipping lorry, 157in. wheelbase; three Ford 14·9 H.P. Tudor saloon cars; one Ford 14·9 H.P. Fordor saloon car.

Morris Commercial Cars, Ltd.—Thirty-eight Morris C 13 type chassis, bodies to be fitted in L.M.S. works; one Morris station omnibus.

Miles, Ltd., Cheltenham.—One Fordson Sussex chassis, with Miles livestock carrying body; one Fordson chassis, with Biflex articulated trailers, one trailer with Miles livestock body and one trailer with flat lorry body.

S.M.T. Company (Alexander Motors), Edinburgh.—Five Fordson Flexion chassis, with livestock carrying bodies.

Jowett Cars, Ltd.—Twelve 10-cwt. light vans.

Scammell Lorries, Ltd.—Six Scammell "Mechanical Horse" tractors.

Cranes (Dereham), Ltd.—Eighteen trailers for "Mechanical Horse" tractors.

Fleet Motors, Birmingham.—One Fleet three-wheeled light delivery van.

J. I. Thornycroft and Co., Ltd.—Eight Thornycroft JC type 10-ton six-wheeled tipping lorries, to be reconditioned and fitted with Gardner compression ignition engines.

CONTRACTS.

Charles Hill and Sons, Ltd., Bristol, have received from the Severn and Canal Carrying Company, Ltd., of Bristol, an order for a vessel to be fitted with a 120 B.H.P. Kromhout engine. It is to be a duplicate of the "Severn Trader," also built by Charles Hill and Sons.

Brooke Marine Motors, Ltd., Lowestoft, have received from the Lobitos Oilfields, Ltd., an order for the urgent construction of a motor tug for shipment to Peru. The vessel will be 45ft. long with a beam of 11ft., and will be used chiefly for the purpose of mooring up the large oil tanks at the end of a pipe line. The engine will develop 80 H.P. at 800 r.p.m.

International Combustion, Ltd., has secured an order from the Rand Water Board, South Africa, to supply and erect two C.S.G. Tri-drum boilers for the Zwartkopjes pumping station, each unit evaporating 70,000 lb. of water per hour at a pressure of 180 lb. per square inch and superheated to 680 deg. Fah. These boilers will be fired by Underfeed "L" type forced draught stokers, and be fitted with Green's gilled tube economisers and M.L.S. superheaters.

The Atlas Diesel Company, Ltd., has received an order from W. T. Lamb and Sons, Ltd., Shoe-lane, E.C.4, for a "British Polar" Diesel engine, type K 35 M, developing 725 B.H.P. at 250 r.p.m. This will be direct-coupled to an Asea 500 kW, 400-volt, three-phase alternator, and will be used for supplying power and light to a new brickworks at Bletchley. Another recent order comprises four 450 B.H.P. engines for driving generators on a new vessel building at Harland and Wolff's yard at Belfast, for the Shaw, Savill and Albion Company, Ltd.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

Current Business.

Several fair-sized contracts have been reported lately, but most of them have been for work in this country, and there is still a scarcity of important overseas business for which British firms may tender. It is reported that the Pearson and Knowles Engineering Company, Ltd., of Warrington, has taken a contract which is said to be valued at £200,000 for the construction of a Bessemer steel plant for the new works of Stewarts and Lloyds, Ltd., at Corby. Sir William Arrol and Co., Ltd., of Glasgow, have secured a contract in connection with the extension scheme of the Scottish Dyes factory at Grangemouth, the value of which is placed at £20,000. The Scottish Dyes Factory is controlled by Imperial Chemical Industries, Ltd. The Department of Overseas Trade announces that the following contracts are open for tender :—South African Railways and Harbours : 288 tons mild steel rivets of various shapes and sizes, to be presented in South Africa by October 16th ; one 15-ton electrically driven portal Titan crane for Port Elizabeth Harbour ; also for the supply of pig iron of approved brands, to be presented in Johannesburg by October 23rd ; about 2414 tons of mild steel to specification C.M.E. 9/1930 in squares, flats, rounds, hexagon section, angles, &c., to be presented in Johannesburg by October 9th. Australia, Electricity Commission of Victoria : Supply of galvanised soft iron and steel wire ; steel strand and wire rope required during the twelve months from the date of acceptance of the tender, which must be presented in Australia by November 25th. Posts and Telegraphs Department : Submarine telephone cable, to be presented in Melbourne by November 14th. Brazil, Rio Grande do Sul State Railways : Sixteen metallic superstructures for new viaducts, including four steel spans of 26 m. and twelve of 25·4 m., to be presented in Brazil by October 13th. City of Belem, Para : Water purification plant, to be presented in Belem by October 14th.

Pig Iron.

The pig iron department continues to be one of the most active sections of the British iron and steel markets. The position on the North-East Coast is particularly satisfactory, as the stocks of Cleveland iron in the producers' hands have been reduced to small proportions, and consumption, for the time being, is larger than production. It is expected that an additional furnace will shortly be blown in, and it is also reported that the furnace which Dorman Long and Co., Ltd., intend to start soon on the production of basic iron for their steel works will later on be turned over to foundry iron. An active business has been transacted with the Scottish light foundries, which are paying the fixed price of 65s. 3d. d/d Glasgow, and 62s. 3d. d/d Falkirk for Cleveland No. 3 iron. Recently, more export business has been done at cut figures, and some fair sized transactions have taken place with Danish buyers. The Midland makers are also finding a steady demand from the light castings makers in that district. Stocks in the makers' hands remain heavy, but the demand seems slightly above production and a gradual decrease in these accumulations is expected. Many of the larger buyers have covered their requirements for some weeks ahead, but the general demand, although it consists chiefly of small orders, amounts in the aggregate to a considerable tonnage. Rather quieter conditions have ruled in the Yorkshire iron market, as many of the Sheffield consumers have arranged their supplies for some time ahead. In Lancashire the demand sharply improved at the beginning of September, and since then the rate of consumption seems to have been well maintained. Some of the engineering concerns have bought fair quantities and there is a better tone in this branch of the industry. Perhaps the worst feature of the situation in Lancashire is the poor demand for textile machinery, which, of course, reacts upon the call for pig iron. Staffordshire, Midland, and North-East Coast brands of foundry iron are quoted at 67s. for No. 3, whilst Northamptonshire foundry is quoted at 1s. 6d. less. Business in the Scottish iron market has been quiet, but there is a fair demand from the foundries, although the local producers are meeting with competition from Indian and English iron.

Semi-finished Steel.

Active conditions continue to rule in the market for semi-finished steel, and the British works producing this class of material are busily engaged. Competition from the Continent is rarely heard of, and although it was known that the Continental Cartel had released a few thousand tons for the British market recently, the movements of the exchange made the selling price too high to be attractive to consumers in this country, and counter bids were not accepted by the Continental works. Business, therefore, was confined to a few odd lots which were required by users who were prepared to pay a high price for Thomas steel for special purposes. The British makers hold their quotations at £5 for billets, 500 ton lots and over, and £5 7s. 6d. for lots of 100 tons or less ; but these are the minimum prices, and in some cases premiums are asked, particularly for tested billets. Lately there has been a better demand for higher carbon material, which ranges from £5 12s. 6d. to £6 12s. 6d. British sheet bars are quoted at £4 15s., although here, again, in some districts works have asked up to £5. In Wales, however, where efforts have been made lately to sell Continental material, the local works have kept to their official figure of £4 15s. d/d for sheet bars and tinplate bars. There is no doubt that some consumers are watching the market in the expectation that if the sterling exchange improves, Continental makers will be in a position to compete for British business. On the other hand, the home makers are confident that the Continent will not sell large quantities at the poor prices they are obliged to take. Considerable resentment is felt by British merchants at the action of the Continental Cartel in doing all its British business in semi-finished steel through the works' selling organisations and refusing to allow the merchants to participate.

Finished Steel Materials.

Business in finished steel materials has been somewhat irregular of late, and whilst in some districts active conditions prevail at the mills, in others orders are being worked off more quickly than new business is coming to hand. Competition in the home market from Continental steel was practically non-existent last week, as the low sterling exchange made the price of Continental material practically the same as that of British steel when the duty was taken into account. Midland makers complain that orders, although increasing in number, are still for the most part confined to small tonnages. The price of Continental steel bars, delivered Birmingham, was £6 14s. 6d., and as the British re-rollers were prepared to take £6 15s. no transactions in Continental steel were reported. Early this week, on the movement of the exchange, the Continental quotation dropped about 4s. 6d.; but this attracted little business. The works in this district are all busy on strip, for which a demand exists which it is difficult to satisfy. On the North-East Coast the position of the various works is more satisfactory than for many years past. A fair amount of railway work is still in hand, and it is expected that the production of this class of material will be increased. The worst feature in this district is the poor demand for shipbuilding steel, as orders for new ships are still scarce. Some of the ship repairers, however, are rather busy, and their requirements provide welcome work for the steel mills. The sheet works on the North-East Coast are well occupied and the flow of orders from the structural steel works is on a good scale. In South Wales the tin-plate industry, which has been experiencing a rather light demand for some weeks, has improved its position lately, the order for oil sizes for the Near East, referred to last week, having provided fresh work for a number of the mills.

Scotland, Lancashire, and Yorkshire.

There is a good deal of unemployed plant in Scotland, but the industry is working under more cheerful conditions than at any time during the past few years. The demand for shipbuilding steel has improved of late, although the shipbuilding contracts placed recently have not been of importance. The works producing railway material are busy, and if the tube makers are not so well employed as they were a month or two back, they still have work to carry them on for some weeks, and there are prospects of new business coming to hand. The sheet works also are busy, and about 3000 tons of the Argentine order for sheets referred to last week has been placed with F. Braby and Sons, Ltd., and Smith and McLean, Ltd. As this order has to be completed by the end of October, the works are already busily engaged upon it. Lancashire steel makers complain that few important contracts have come their way of late, and this policy of buying in small tonnages necessitates frequent changes of the rolls, and adds to the overhead charges. Some of the structural engineers have bought rather more freely of late, but the demand from this branch of the trade leaves room for considerable expansion. Locomotive builders in Lancashire are not well off for work, and as a consequence the demand for boiler plates is limited. Business in special alloy steels, however, has been maintained, and there has been an improvement in the business in bright bars. In Yorkshire the steel markets are steady without any outstanding feature. The Sheffield rolling mills are working at a high rate, whilst the tool steel makers are busy. There has also been some increase in the demand for alloy steels, although the call for magnet steel has declined.

Finished Iron.

There is more activity in this section of the market than is customary at this time of the year, particularly in the Midlands. Some useful inquiries are reported to have been circulated, and now the holidays are over it is anticipated that the requirements of the railways and wagon builders will be on a fair scale. This is the more probable as this industry has received little support from the railways, which are normally its best customers. Prices are unaltered, marked bars being £12, with Crown bars at £8 10s. to £9 10s. The Lancashire works report only a quiet demand for iron bars, but there has been no alteration in prices in this market, the quotation being for Lancashire best bars £9 10s. and for Crown bars £9. There has not been much pressure on the Scottish bar iron rollers and most of the business reported of late has been in horseshoe iron. A certain amount of business has also been done in iron strip for the manufacture of gas pipes. The minimum price quoted for Scottish Crown quality bars is £9 15s. d/d Glasgow, whilst for export the price is £9 5s. f.o.b. The position with regard to this material, however, is similar in all districts, and although there are encouraging signs in the market the demand will have to greatly improve before the situation at the works can be described as satisfactory.

Ferro-alloys.

The position in this market has become somewhat confused owing to the movements of the exchange. Business is difficult and the tendency for trading to expand has been checked, as buyers have adopted a cautious policy, and have declined to enter into commitments excepting at fixed prices. The position of sellers is equally uncertain, since the fluctuations of the exchange have made it difficult for them to quote firm prices or to arrange forward contracts over a period. A certain amount of business, however, has been transacted in small parcels for prompt delivery. The demand for ferro-chrome has been moderately good, but in one or two cases low-carbon grade material has been sold at cheap prices. Quotations received from abroad for the higher carbon grades have been at advanced rates, as the figures were based on gold quotations. As a result, little business has resulted. Somewhat similar conditions have ruled in the market for ferro-silicon, and although no change has been made in the quotation for home delivery, export business has been almost impossible to arrange. The demand for tungsten remains poor, but, on the other hand, holders are not pressing sales and, in some cases, supplies have been divided amongst consumers. This is owing to the difficulty of obtaining supplies of ore, as the Chinese are still restricting the quantities they offer and are declining to renew contracts which have expired. On previous occasions Chinese sellers have endeavoured to squeeze the market. Fresh sources of supply are being sought in Peru, Portugal, and, to some extent, in Cornwall.

Copper.

The position in the electrolytic copper market does not improve, and consumers in Europe and America are probably still awaiting the result of the "Code" experiment before committing themselves to forward purchases. A few weeks ago sufficient copper was bought to enable consumers in the United States to carry on well into the autumn without making fresh purchases, whilst in this country and on the Continent, although stocks are low, users are not busy, and are well able to await events. It is certain that the possibility of a fall in the price of copper if the American experiment does not succeed is present in the minds of most users of the metal. The American producers have held their official price at 9 c. d/d, but this figure has been shaded by second hands. On this side of the Atlantic the producers have done their best to increase the demand by making cheap offers to the manufacturers of finished copper materials, without achieving much success, although the sterling price has slipped back to £39 c.i.f. One of the features of the position is that little attention is now paid to the dollar price, as the American market is of lessening importance to this country, supplies of copper from the Empire and other sources being sufficient to meet requirements. As a consequence, the sterling quotation at times seems to have little relation to the American price. Anticipations are rife that the statistics for August will show a substantial reduction in the American stocks, and this, of course, should have a sentimental effect upon the world position.

Tin.

After showing some weakness, the tin market became firmer at the beginning of this week. For the time being the market seems to have lost confidence, but probably this is merely the effect of the decline in American buying, which for some time past has been confined to spasmodic movements and latterly has practically ceased. Another reason for the easier tendency in the market was the suspicion entertained in some quarters that the tin production quota will be increased before the end of this year. Other authorities, however, cannot believe that the Tin Control will make any change in the quota before next January, and this view has become the more generally accepted one. It is thought that a good deal of the tin recently offered on the market, and which has had something to do with the recession in prices, was metal released by the Pool. Tin is still being taken out of Liverpool warehouse in considerable quantities for shipment to the United States ; but another conflicting factor in the position is that second-hand sales have been made in America on a substantial scale. This indicates that some of the tin which it was claimed some weeks ago was going into consumption in the United States was really metal purchased by investors who expected to see an advance in the price, and who are now returning it to the market. This will naturally have a damping effect upon speculation. Although it is early days to forecast the September statistics, it is anticipated that they will show a further decrease in the visible supply.

Lead and Spelter.

The lead market has been featureless for the past week or two, and prices have shown a tendency to recede. The demand from the consuming trades, particularly those supplying the building industry, has been fairly good. In fact, a short time ago a number of unusually heavy contracts were placed with the manufacturers of lead products, against which they immediately bought their supplies of raw metal, so that unless a fresh demand develops from the building and associated trades, there is not likely to be a great deal of buying from this source. Other consuming industries are responsible for a steady demand. On the other hand, the production of lead is in excess of requirements, and although of late there has been no attempt to press sales, the producers have not held back supplies. At present levels, however, the price is regarded as low, and any revival in buying would be likely to have an immediate effect upon values. . . . Steady conditions have ruled in the spelter market this week, and prices have fluctuated within narrow limits. The situation in this market is regarded as being particularly sound, as it is generally understood that stocks in Europe are declining and that consumption, particularly on the Continent, is on the increase. The American statistics for August also were satisfactory, inasmuch as they showed a reduction in the stocks of 8900 tons, bringing the total to 100,247 tons, which is the lowest figure recorded since May, 1930. More speculative interest has been taken in the market, and there is a bull account open which the holders show little inclination to liquidate. A considerable tonnage of September spelter was declared on the market, but was quickly absorbed. One of the disappointing features of this market is still the poor demand from the galvanisers. There has been an improvement in business in galvanised sheets, and it is hoped this may result in more buying from that industry.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

Confidence and Trade.

THE industrial activity that accompanied the collapse of the franc seven years ago, when everyone spent their money on manufactured goods of tangible value, was an instance of what may follow temporarily on loss of confidence in a nation's currency, but any permanent activity can only come from confidence, which feeling it is now sought to stimulate on the ground of rising prices. Notwithstanding the publication of official index figures purporting to show a decline in the cost of living there is visible evidence of an increase in prices, which is one direct result of an exaggerated system of import restrictions that eliminate competition on the home market and create a scarcity of certain commodities. This again combines with taxation and charges to inflate production costs, particularly in relation to costs prevailing in some countries with depreciated currencies. The possibility of a continued inflation is being made use of to organise propaganda designed to encourage consumers to "Buy now." If such a movement can be accelerated, it is hoped that it will create confidence amongst consumers who will continue to buy on a rising market. This should benefit the engineering trades, in which there has lately been a more confident tone, and it is probable that they would respond readily to any success of these efforts to encourage the expenditure of money.

The Navy.

The recent death of Monsieur Georges Leygues recalls the part he played in reconstituting the Navy which had been left by the war totally inadequate for the country's needs. He presented his programme of construction in 1920, with the proviso that it should be carried through as it stood, without modifications that would impair the homogeneous character of the new fleet. The danger of successive Ministers of Marine imposing their own ideas had been revealed before the war, when the French Navy had become what was commonly called a "collection of samples." The determination with which Monsieur Leygues carried through his plan did not make things easy for the Conseil Supérieur de la Marine and the Commission de la Marine in the Chamber of Deputies, when it became evident that the development of the German Navy could only be countered by the construction of battleships. The Minister insisted on the light cruisers being put on the stocks this year, despite the advice of the Commission that, for reasons of economy, they should be held over in view of the expenditure on the "Dunkerque." Since the programme was put in hand, 291,500 tons of ships have been built. Monsieur Leygues also aimed at increasing the efficiency of the Navy by remodelling the system of training, building the new naval college at Brest, replacing the old cruiser used as a training ship with a specially built "Jeanne d'Arc" which can navigate all seas, and sending ships on commission to colonial and foreign ports. He also retained for the Navy control over its special branch of aviation, at a time when it was proposed to concentrate the entire organisation in the Ministry of Air. The late Monsieur Leygues is succeeded as Minister of Marine by Monsieur Albert Sarraut, the former Colonial Minister.

Energy from Warm Water.

The Claude-Boucherot system of utilising the difference between surface and deep-water temperatures in tropical seas for the production of energy having failed to pass beyond the experimental stage, Monsieur Georges Claude has communicated his plans to the Académie des Sciences for testing the system on a small scale by means of a plant to be installed on a cargo ship of 10,000 tons, which is now being fitted out by the Chantiers de France at Dunkirk. It is expected that the equipment will be completed in about ten months' time. The ship will be anchored off a tropical coast, where it is hoped to demonstrate the possibility of producing ice cheaply in sufficient quantities by this system to modify the conditions of existence in the tropics.

Level Crossings.

The suppression of level crossings is again being advocated, as the result of collisions between motor cars and trains, which are becoming more frequent with the growth of road traffic. It was decided some years ago to suppress these crossings, and this has been done in the more dangerous cases, but the cost of carrying roads above or below railways is so considerable that the work is hampered by want of funds. The railway companies declared that it could only be done with money provided for the execution of the national programme of public works, but as the necessary funds have not been voted the suppression of level crossings has made little progress. The companies are doing their best to ensure safety by means of long distance caution signals, with danger signals that indicate automatically the closing of gates. Many systems are being tried. A method of signalling that depends upon the closing of gates is not always reliable, as was shown again last week when two collisions between motor cars and trains, involving the loss of several lives, were caused by failure to close gates. The problem has become a serious one with the extraordinary development that is taking place in road traffic.

A Big Dredger.

The entrances to most French ports in the Channel need constant dredging, and the work of deepening them for ships of increased draughts necessitates the use of dredgers of larger capacity, one of which, launched last week from the Chantiers de France at Dunkirk, is declared to be the biggest yet built. This dredger, the "Pas de Calais II.," has a length between perpendiculars of 69 m., and is equipped with two engines, each of 1040 H.P. For dredging one of the engines is disconnected from a propeller shaft to drive the chain buckets. The dredger is capable of raising 600 cubic metres of spoil an hour.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office, Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

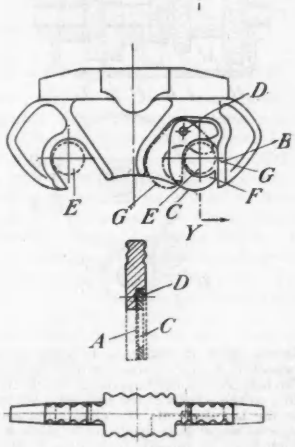
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

STEAM GENERATORS.

396,457. February 10th, 1932.—LINKS FOR TRAVELLING CHAIN-GRATE STOKERS, Brian Mundell Thornton, of Winnington Hall, Northwich, Chester; and Imperial Chemical Industries, Ltd., of Imperial Chemical House, Millbank, London, S.W.1.

Links or grate bars for travelling chain-grate stokers are designed, in accordance with this invention, so that they can be easily replaced without involving the shutting down of the furnace and dismantling of the grate or even the stoppage of the grate. The side surface of the link is recessed or inset at A adjacent to the slot B, the hook C swinging freely on a small projecting pivot D. The dotted outline G of the hook shows it in the open position, prior to insertion of the link into position over the pivotal support E. Upon insertion, however, the pivotal support takes up the position shown and the hook is swung into the position C, thereby closing the open end of the slot and locking the link into position.—*August 10th*, 1933.

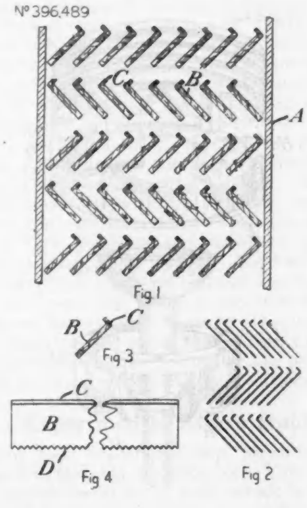
Nº 396,457



396,489. March 19th, 1932.—SCRUBBERS FOR USE IN THE TREATMENT OF GASES, London Power Company, Ltd., and Standen Leonard Pearce, both of Ergon House, Horseferry-road, London, S.W.1.

A scrubber built in accordance with this invention for use with a process for cleaning or purifying flue or other gases consists of an outer casing A and superposed rows or layers of boards B or plates of wood, metal or other suitable material, the layers of plates or boards running horizontally across the tank, chamber or tower A. The boards or plates of the respective layers are parallel to one another and arranged at an inclination to the horizontal, those in one row, for example, sloping downwards towards the left, while those in the next adjacent row slope downwards towards the right, and so on throughout the whole series of rows or layers. Each board or plate is provided at its upper edge with a strip or fillet C which may be secured upon the face of the plate, as shown in Fig. 1, or upon the end thereof, as shown in Fig. 3, and which is disposed substantially at right angles to the plate or board. The outer upper edge of the latter or the outer lower edge of the fillet is rounded and the lower edges of the boards of one layer are so disposed relative to the fillets of the next lower layer that the liquid from a higher layer is caught by the fillet and is conducted to the underside of the board or plate of the lower layer. The boards or plates of each layer are spaced apart so that the upper edge of one board or plate slightly overlaps the lower edge of the adjacent board or plate. The layers or rows may also themselves be somewhat spaced apart, the arrangement being such that while very intimate contact between the gas and the treating liquid can be obtained there will be no undue resistance to the passage of the gas through the scrubber. When the plates or boards show a tendency to sag or warp in such a manner as to collect the flow of washing medium to a greater extent at one part of the board than at others a substantially even flow of washing medium over the whole length of each board or plate may be ensured by providing the lower edge with a serrated or similar formation D, as shown in Fig. 4. Fig. 2 shows a series of scrubber plates formed of metal in which the fillet at the upper edge of each board is formed as a flange by bending the metal plate.—*August 10th*, 1933.

Nº 396,489

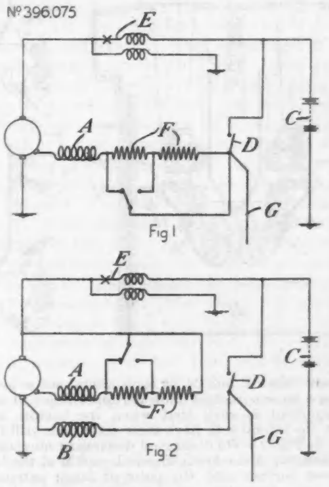


DYNAMOS AND MOTORS.

396,075. January 28th, 1932.—DYNAMOS FOR MOTOR VEHICLES, Joseph Lucas, Ltd., of Great King-street, Birmingham; Oliver Lucas and Ernest Owen Turner, both of the same address.

When a dynamo is employed on a motor vehicle for charging a battery which supplies current to an engine starting motor ignition system, lamps and other electrical accessories, the dynamo is ordinarily of the self-exciting type. Before the dynamo comes into action it is necessary that its speed shall have reached a predetermined lower limit. At and above that speed the dynamo is connected to the battery, and remains so connected, under the control of an automatic switch, until the dynamo speed falls below that at which the switch automatically re-opens. Modern developments in the electrical equipment of motor vehicles, such as the introduction of mechanisms whereby the engine is automatically re-started in the event of unintentional stoppage, or the controlling of the disconnection of the starting motor from the engine by conditions dependent on energy supplied by the dynamo, have led to difficulties with dynamos of normal construction, owing to the fact that the dynamo must attain a considerable speed before it can be relied upon to supply the required energy. The object of the present invention is to obviate these difficulties.

Nº 396,075

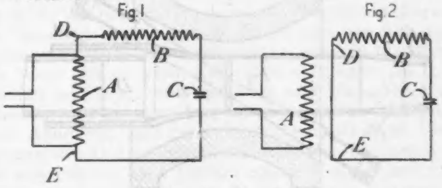


In carrying the invention into effect, as shown in Fig. 1, the normal field winding A is employed for excitation. Alternatively, as shown in Fig. 2, an additional winding B may be employed. The connection of the field winding with the battery C is effected by a hand-operated switch D. After the switch has been closed the dynamo begins to generate immediately the engine is started, and the voltage produced is approximately proportional to the dynamo speed until it reaches that of the battery. Thereafter the dynamo is caused to operate normally with self-excitation through the closing of the automatic switch E. If the engine speed falls below the speed at which the dynamo generates the battery voltage, the switch E re-opens and separate excitation is resumed. When the engine stops the switch D is opened. It will be noticed that the switch D is connected at one end to a position between the automatic switch E and the battery so that current can flow to the dynamo field winding independently of the condition of the switch E. In Fig. 1 the resistances F in series with the field winding are the ordinary resistances used to control the field winding and form no part of the invention. In Fig. 2 these resistances are shown in the normal field winding circuit which is separate from that controlled by the switch D. If desired, the same switch D may also be used to control a circuit connected with the ignition apparatus as indicated by the line G.—*July 28th*, 1933.

396,259. December 23rd, 1932.—ALTERNATING ELECTRIC CURRENT MOTORS, Edgar Wall Dorey, of Avenue Chambers, Vernon-place, Southampton-row, London, W.C.1.

The object of this invention is to provide improved arrangements for controlling the phase of the current traversing the windings of induction motors with a view to promoting starting and effecting an improvement in the power factor of the load constituted by the motor. The usual stator winding of a single-phase induction motor is indicated at A, the stator being also provided with an auxiliary winding B connected in series with a condenser C. The winding B is preferably arranged in slots in the magnetic core of the motor in the same manner as the usual starting winding, and during starting the terminals D E of the auxiliary circuit constituted by the winding B and the condenser C in series with one another are arranged to be connected to the terminals of the main winding A, as shown in Fig. 1. The auxiliary winding B then operates as a starting winding, the current traversing this winding having a leading phase relative to the current traversing the main winding A. It will be evident that the voltage impressed upon the terminals D and E cannot exceed the voltage impressed upon the winding A, and by connecting these terminals to intermediate points in the winding A the voltage across the terminals of the auxiliary circuit and thus the voltage across the terminals of the winding B and across the condenser C can be determined as desired. As soon as the motor has attained its normal or a predetermined speed the terminals D E of the auxiliary circuit are disconnected from the winding A and connected together, as shown in Fig. 2, so that the auxiliary

Nº 396,259



winding B and the condenser C are included in a closed circuit. Under these conditions the auxiliary circuit operates to improve the power factor of the load constituted by the winding A, and since the voltage impressed upon the terminals of the condenser C is positively determined by the electromotive force induced in the auxiliary winding B by the current traversing the winding A, this voltage can by suitably designing the winding B be arranged to correspond to the terminal voltage of a standard type of condenser.—*August 3rd*, 1933.

SWITCHGEAR.

396,488. March 19th, 1932.—HEAVY DUTY CIRCUIT BREAKERS, Herbert Astbury, of Coval-avenue, Chelmsford, Essex; and Crompton Parkinson, Ltd., of Netherfield Works, Guiseley, near Leeds.

The operation of the circuit breaker constructed in accordance with this invention is described as follows:—Assume the circuit breaker is closed, as shown in Fig. 1, and that by reason of overload it is released to open. The moving insulator A commences to move downwardly and carries down with it the pivots of the bell crank levers B C and D E. Under the action of their springs F and G these rock and carry the lower ends of their depending arms away from one another. This results in the separation of the main parts of the bottom pair of contact fingers and causes contact of the extensions J and K thereof, which roll on one another and finally separate. During this movement the contact finger L and M of each lateral set is lowered and at the same time is rocked upon its upper finger O and P, but the arrangement is such that when the bottom set is fully separated the lateral sets have their extensions still in contact, as shown in Fig. 2. On continued downward movement of the moving insulator A the lower fingers L and M of the lateral sets are lowered further and the pairs of finger extensions rock further upon one another and finally separate, forming two further breaks in the circuit in series with the first break, as shown in Fig. 3. The movement is such that the first bottom contacts open with great rapidity. Owing to the high pressure generated between the first contacts on opening under heavy fault conditions, the effect of an oil blast is obtained by displacing oil within the tank towards the lateral pairs of contacts.—*August 10th*, 1933.

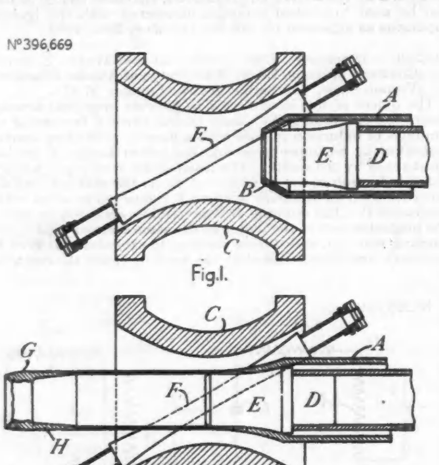
MACHINE TOOLS AND SHOP APPLIANCES.

396,669. May 2nd, 1933.—PRODUCING AN END THICKENING IN TUBULAR BODIES MADE BY ROLLING WITH SKEW ROLLS, Heinrich Esser, of Hagelkreuzstrasse 37, Hilden, Rhineland, Germany.

Although the forming of a thickening of the wall at the end of tubes is of great importance for the connection of the tubes with one another, it cannot be effected conveniently by the tube-manufacturing methods usually employed. According to the invention the hollow body A coming from the piercing rolls passes, as it travels to the reducing skew rolls, a press or a hammer (not shown), where, by upsetting it at the end or forging it in a die, the constriction B, Fig. 1, is produced. As the hollow body leaves the piercing rolls at a sufficiently high temperature and the operation of drawing it in can be carried out in a few seconds, there is no serious loss of heat and the hollow body can be passed directly after being forged to the skew rolls. In the rolls C the withdrawn mandrel D is pushed into the blank, until the mandrel head E bears against the constriction B. On the mandrel D being pushed further forward, the hollow body is pushed between the rolls until the blank is seized by the rolls F, Fig. 1. The constriction B will then bear against the forward end of the mandrel and is reduced by the rolls without the mandrel being forced forward to the external finished diameter of the tube, the thickening G, Fig. 2, being thus produced. The mandrel then moves forward into the final rolling position, Fig. 2, the part H adjoining the thickening G gradually widening, corresponding to the forward motion of the mandrel, to the internal diameter of the finished tube.—*August 10th*, 1933.

N°396,669

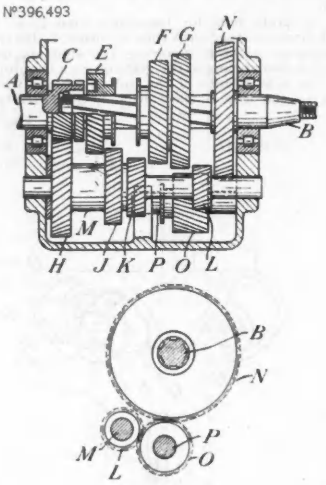


MOTOR CARS AND ROAD TRAFFIC.

396,493. April 4th, 1932.—CHANGE-SPEED GEARS, Zahnradfabrik Friedrichshafen Aktiengesellschaft, of Friedrichshafen, Lake Constance, Germany.

This invention relates to change-speed gears for motor vehicles of the type having a driving shaft, a driven shaft, a lay shaft, and a second lay or reversing shaft carrying an idler wheel for reverse gear, all the toothed wheels being of the helical type and the displaceable wheels being carried by the helically splined driven shaft. The object of the invention is to construct a relatively simple four or a greater even number of forward speeds and reverse gear of the above kind. The driving shaft A and the driven shaft B are coaxial. On the former there is the wheel C and the driven shaft B, which is helically grooved, carries the sliding wheels E, F, and G necessary for obtaining the forward speeds. The helically toothed opposing wheels H, J, K, and L corresponding to the wheels of the two main shafts are fixed in common on the lay shaft M. To enable the reversing to be effected a special wheel N is fixed on the shaft B, the inclined teeth of which have an opposite inclination to the teeth of the other wheels on the shaft B and to the course of the helical grooves of the shaft B. A double width sliding wheel O, arranged on the reversing shaft P, can be brought into gear with this wheel N, and in its turn the wheel O is in constant mesh with the wheel L on the lay shaft M.—*August 10th*, 1933.

N°396.493



MISCELLANEOUS.

396,407. February 2nd, 1932.—UNIVERSAL JOINTS, Christopher George Nevatt, of "The Haven," Waterford-road, Henleaze, Bristol; and Ernest George Kingston, Secretary of the Bristol Tramways and Carriage Company, Ltd., of Clare-street House, Bristol.

The object of this invention is to construct a universal joint with light parts offering a large surface to take pressure and giving equal expansion when heated. The piston A is hollow with one end closed. It has six internal radial ribs B, which reach to the closed end and constitute the sole connection between the main body of the piston and a skirt C. Apertures are left between each adjacent pair of ribs. The piston is open at the end at which the skirt is located and inside the piston, supported by the ribs B, there is an annular flange D, which carries a cup E of spherical contour with its convex face directed towards the open end of the piston. The cup lies wholly within the interior of the piston and the ribs B extend down its concave face to support it, the flange D being substantially radial with respect to the cup. The connecting-rod F has a cup G at one end with a concave face. The cup is of spherical shape, the concave face corresponding in curvature to the convex surface of the cup E. The flange D is perforated at H to permit a retaining cap J to be bolted to it, the apertures in the piston between the ribs B permitting of access to the bolts for tightening. The retaining cap J is divided diametrically into two parts so as to permit it to be readily placed in position, and it has a spherically shaped concave surface K corresponding in curvature to the convex face of the cup G. When the cap J is bolted in position in conjunction with the cup E it constitutes a housing in which the cup G is a close fit with freedom to slide to take up a variety of angular settings.—*September 30th*, 1932.

Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the TIME *and* PLACE *at which the meeting is to be held should be clearly stated.*

TO-DAY.

IRON AND STEEL INSTITUTE.—Autumn meeting at Sheffield. For programme of papers to be discussed see page 169.

RAILWAY CLUB.—57, Fetter-lane, E.C.4. "Some Suggested Improvements in London Train Services," Mr. H. A. Vallance. 7.30 p.m.

TO-DAY TO WEDNESDAY, SEPTEMBER 20TH.

ALUMINIUM CONFERENCE AND EXHIBITION.—Curio House, Hamburg. Sessions, Thursday, September 14th, 10 a.m.; Friday, visit to Hamburg Experimental Tank, 9.30 a.m.; Saturday, visit to Rhenania Ossag Works, Harburg, 9 a.m. Embark on East African Line s.s. "Njassa" for Heligoland, 1.30 p.m.

TO-DAY TO SATURDAY, SEPTEMBER 23RD.

SHIPPING, ENGINEERING AND MACHINERY EXHIBITION.—Olympia, London, W. Daily, 11 a.m. to 9 p.m.

MONDAY TO THURSDAY, SEPTEMBER 18TH TO SEPTEMBER 21ST.

INSTITUTE OF METALS.—Autumn Meeting in Birmingham. For provisional programme see page 98.

WEDNESDAY, SEPTEMBER 27TH.

INSTITUTION OF WELDING ENGINEERS: NORTH-WESTERN BRANCH.—Manchester College of Technology, Manchester. "Experiences by Practical Welders." Speakers, Messrs. W. Bellingham, W. W. Ely, C. Peat, and E. W. Hart. 7.30 p.m.

SATURDAY, SEPTEMBER 30TH.

MANCHESTER ASSOC. OF ENGINEERS.—Visit to works of Henry Simon, Ltd., Cheadle Heath. 2.15 p.m.

TUESDAY, OCTOBER 3RD.

INST. OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND.—Elmbank-crescent, Glasgow. Presidential Address, Professor J. D. Cormack.

WEDNESDAY TO SATURDAY, OCTOBER 4TH TO OCTOBER 14TH.

INSTITUTE OF PATENTEES.—Central Hall, Westminster, S.W.1. Ninth International Exhibition of Inventions. Daily.

THURSDAY, OCTOBER 5TH.

STEPHENSON LOCOMOTIVE SOCIETY.—No. 1, Dining Club, King's Cross Station, N.1. "The Railways of South Wales," Mr. D. S. Barrie. 6.30 p.m.

FRIDAY, OCTOBER 6TH.

INSTITUTION OF SANITARY ENGINEERS.—Caxton House (Hill's Restaurant), Tothill-street, Westminster, S.W.1. Opening sessional meeting. Reception, 7.30 p.m.; music and dancing, 8 p.m. until 11.30 p.m.

JUNIOR INST. OF ENGINEERS.—39, Victoria-street, S.W.1. "Education with Particular Reference to the Engineer," Mr. K. W. Willans. 7.30 p.m.

RAILWAY CLUB.—57, Fetter-lane, E.C.4. "Permanent Way," Mr. W. A. Willox. 7.30 p.m.

THURSDAY, OCTOBER 12TH.

ROYAL AERONAUTICAL SOCIETY.—At Royal Society of Arts, John-street, Adelphi, W.C.2. "Air Traffic Control," Major R. H. S. Mealing. 6.30 p.m.

FRIDAY, OCTOBER 13TH.

INST. OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND.—Grosvenor Restaurant, Glasgow. "James Watt" dinner.

JUNIOR INST. OF ENGINEERS.—39, Victoria-street, S.W.1. "The Influence of Harmonics in Transformer Circuits," Mr. E. Ambrose. 7.30 p.m.

FRIDAY, OCTOBER 20TH.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—Bolbec Hall, Newcastle-upon-Tyne. Annual general meeting. Address by the President, Mr. R. J. Walker; cinematograph film, "Mechanism of Ships' Wake," Professor T. B. Abell.

SATURDAY, OCTOBER 28TH.

STEPHENSON LOCOMOTIVE SOCIETY.—Visit to Stratford, L.N.E. Railway Running Sheds. 2.30 p.m.

LAUNCHES AND TRIAL TRIPS.

SOUTHERN CROSS, motor yacht; built by Cammell, Laird and Co., Ltd., to the order of the Melanesian Mission Trust (England), Ltd.; dimensions, 120ft. by 28ft. 6in. by 12ft. 6in. Oil engines, Gardner type; launch, September 4th.

BARON ELGIN, steel screw steamer; built by David and William Henderson and Co., Ltd., to the order of Messrs. H. Hogarth and Sons, Glasgow; dimensions, 365ft. by 51ft. 6in. by 26ft.; to carry cargo. Engines, triple-expansion, 21½in., 37in., 62in., by 42in. stroke; pressure 210 lb. per square inch; constructed by the builders; launch, September 6th.

PERSONAL AND BUSINESS ANNOUNCEMENTS.

MR. J. T. H. LEGGE has been appointed managing director of Edmundsons Electricity Corporation, Ltd., as from September 1st, 1933. Mr. A. N. Rye, formerly managing director, who has been associated with Messrs. Edmundsons for many years, has retired.

GILBERT GILKES AND GORDON, Ltd., Kendal, England, have taken over the water-power connection of Messrs. W. Gunther and Sons, the partners having decided for private reasons to retire from business. Under this arrangement Messrs. Gunther's drawings, data, patterns, &c., have been removed from Oldham to Kendal.

MR. A. P. M. FLEMING, director and manager of the research department of the Metropolitan-Vickers Electrical Company, Ltd., has been reappointed local Honorary Secretary for Great Britain of the American Institution of Electrical Engineers, for the two-year term beginning August 1st, 1933. Particulars and forms of application for the various grades of the A.I.E.E. can be obtained from him.

THE DRAYTON REGULATOR AND INSTRUMENT COMPANY, Ltd., West Drayton, Middlesex, England, has acquired the exclusive manufacturing licence for the British Empire for instruments manufactured by Union Apparatebau m.b.H. Karlsruhe i.B. These instruments comprise a range of indicators and recorders for very light pressures, simple and differential; volume, density and heat value.

A Seven-Day Journal

Hire-Purchase.

It was announced a few days ago that in nearly forty cities and towns in Great Britain an important and far-reaching plan for the control and development of hire-purchase trading is to be put into operation almost immediately. In consequence of a considerable speeding up of preliminary inquiries and other matters of routine, long and medium-term credit will be more quickly available to approved purchasers. The new plan, which has been evolved by the mutual trade protection movement throughout Great Britain, in co-operation with Bankers Commercial Security, delegates to local trade protection societies the approval of credit risks and the receipt of payments. The scheme has been adopted by the International Association for the Promotion and Protection of Trade in London and other centres, and many of the mutual provincial societies affiliated to the National Association of Trade Protection Societies. This Association, which is nearly a century old, has a membership of 40,000 manufacturers, wholesalers and retailers. All phases of distribution and its financing are provided for in the plan. The manufacturer, whose relations are with the retailer or directly with the user, and the wholesaler operating either nationally or in prescribed areas, will, it is stated, have the advantage of a national credit machine covering practically every important trading centre. Such a system, in addition to operating much more quickly than a remote central office, will allow each transaction to be judged in the light of local knowledge and conditions. The retailer, in dealing with long-term credit sales, will refer the customary preliminary inquiries to the local trade protection society, on whose recommendation the sale will be financed. Afterwards, the society will receive the payments as they become due.

A New Telephone Cable.

On Monday, September 18th, the work of laying a new telephone cable between St. Margaret's Bay, Kent, and Calais, was completed, and from the beginning of November telephoning across the Channel will be greatly facilitated. It is said, in fact, that it will be possible to put through calls to Paris in little more than a minute. A new repeater station at St. Margaret's Bay will strengthen the calls of English subscribers who will be able to speak through their own instruments to over nine-tenths of the world's telephone users. The amplifying apparatus has already been installed in the station, which will be ready for service in about six weeks. Only one attendant will be necessary to supervise the working of the station. The number of lines from Calais to the Kent coast has been increased from forty to sixty, and with the extension of the "on demand" service across the Channel, Paris will be telephonically as near London as Birmingham. While shortly after the war England had telephone communication with only two countries—France and Belgium—at the present time practically every country in the world is connected with London.

Gift to Sheffield University.

In connection with the meeting of the Iron and Steel Institute at Sheffield last week and the presidency of his friend Mr. W. R. Lysaght, Sir Robert Hadfield announced his intention of presenting a gift of £5000 to the University of Sheffield, in order to commemorate the visit of the Institute in 1905 when he was President. The gift will be formally received at the next meeting of the University Council, and it is understood that Sir Robert's wish that the money be spent on the advancement of metallurgical knowledge will be honoured. This is not the first time that Sir Robert Hadfield has benefited the Sheffield community, for we recall his previous generous gifts to Firth College, the research laboratory of the Applied Science Department, the Cutlers' Company, and other local bodies. It is well known that Sir Robert has expressed warm approval of the suggestions recently made by Dr. J. H. Andrew, the Professor of Metallurgy at Sheffield University, with regard to the establishment of a course for foundry workers within the Faculty of Metallurgy, which he referred to in his letter to the Vice-Chancellor of the University. The money given by Sir Robert may possibly form a nucleus of a fund for this special purpose.

Oil from Coal.

The Industrial Development Council of South Wales and Monmouthshire considered on Monday the details of the scheme prepared by the Sub-committee of three, consisting of Professor George Knox, Dr. Roy Illingworth, and Mr. H. H. Merrett, for the production of oil from coal. The scheme, which met with considerable criticism and was even described by one of the authors of the memorandum as a highly speculative proposition, is to be further reported upon, the Sub-committee being given plenary powers to select as many additional members as may be considered advisable, representing all interests. That enlarged committee is to report to a future meeting of the Council. The memorandum states that assuming one hydrogenation plant and ten 1000-ton L.T.C. plants are distributed along the south-eastern outcrop of the coalfield, the total cost may be estimated at £7,000,000. The hydrogenation plant would produce 100,000 tons of petrol per annum, using about 365,000 tons of coal, and find permanent employment for 1000 miners and 1500 process workers. Its construction would also give temporary employment to about 15,000 men for a period of one year. Ten 1000 L.T.C. plants would treat 3,650,000 tons of coal per annum, producing about 240,000 tons of heavy oil, 40,000 tons of light oil, 70,000 tons of pitch, 3,220,000,000 cubic feet of surplus gas, and 2,520,000 tons of smokeless fuel. These plants would find permanent employment for 4000 miners and 1400 process workers and temporary work for 12,000 men for one year. The combined plants would therefore use over 4,000,000 tons of coal annually and produce about 1,500,000 tons of liquid and gaseous fuel and 2,500,000 tons of smokeless fuel. An alternative scheme would be to limit the hydrogenation process to the oils produced from the L.T.C. plants, together with what could be obtained from gasworks, coke ovens, &c. This scheme would cut down the initial capital expenditure by about £2,000,000, and produce a more profitable yield, as the tar oils worth £2 10s. per ton would be converted into petrol worth £15 per ton.

Finance for Small Firms.

"British industry is now experiencing a severe reaction against the wholesale rationalisation which was recently looked upon as a universal panacea," said Mr. Stanley Townsend, secretary, British Data Service, to the Dartford Rotary Club on Tuesday. It was worthy of note, he said, that in America, the smaller firms had on the whole weathered the storm more successfully than the large units. Improved standards of management in the small and medium-sized firms had reduced the advantages of mere size as such. But more adequate facilities for obtaining finance were urgently required for the small and medium-sized firms, which were at a great disadvantage in approaching the public as compared with the large company and yet frequently offered better security to the investor. Many small firms were to-day starved for more capital, which they required for such purposes as financing mechanisation and widening their sales. At the same time, the investor was showing a greater interest in the small firm, which was under the continuous control of a full-time board, in preference to companies controlled by directors whose presence was, to say the least, intermittent. "In my view," added Mr. Townsend, "a duty rests upon the City of bringing into effective relationship the investors who want to put their money in the sound small firms, and the small firms which are in need of further capital. There is room for a new type of investment trust designed to fulfil these purposes."

The Use of Mechanical Power.

Speaking at a luncheon at Birmingham on Thursday last, September 14th, on the subject of "Power," Mr. Walter F. Higgs, of Higgs Motors, Ltd., Witton, expressed some doubt as to whether mankind had attained to any greater happiness by the introduction during the past 150 years of mechanical power in its various aspects. It had come, he said, and it was going to stay, because it was man's natural function to wrest from Nature her mysteries, but it was discovery and not the ultimate result of discovery that really caused satisfaction to man. Amongst the things which it had brought in its train were the rapid transport of thought and matter, added ease and comfort, perhaps, certainly undesirable artificial light, bad housing conditions through the industrial revolution, noise, deaths through mechanical accidents, and the great slaughter of war. All these things had come about during the last 150 years. What about the next 150 years ? From the engineering point of view, Mr. Higgs said, he believed we were at the lowest rung of the ladder. We had been in possession of a tool which we had not known how to use, and the next 150 years would afford us the opportunity of learning how to use it. Our inventions would be along the line of improving man's lot. We would house people better, distribute the population better, and the land would be better cultivated.

An Experimental Ship's Hold.

On Friday last, September 15th, an official visit was arranged to the Ditton Laboratory, East Malling, where an experimental ship's hold, which is used for the study of biological engineering problems connected with the grading and packing of apples and their behaviour under conditions of sea transport, was inspected. The hold is now being prepared and filled with apples for the coming season's work, a process which usually occupies about two weeks. This year's experiments are being made with a special kind of wooden case employed in the Australian fruit trade, with the object of studying the shape of the case and its relation to air distribution between the cases, and the effect on the maintenance of a uniform temperature within the hold space. The experimental hold, inside the insulated walls, measures 34½ft. by 30½ft. by 15ft., has a capacity of nearly 16,000 cubic feet, and can take a "cargo" of approximately 130 tons, or 7000 bushel boxes, of apples when fully loaded. It can be refrigerated either by means of brine pipes inside the hold or by circulating air by means of fans over an external cooler and back again through the cargo. These methods on a ship, corresponding respectively to the grid system and the battery system of refrigeration, are capable, however, of a number of modifications which can be tested in turn in the experimental hold. Over 200 thermometers are used to obtain temperature readings, many of them distant recording instruments, so that readings may be taken over definite periods corresponding to a ship's watches, and the results plotted in curve form. Investigations are also made on the shape of intermediate air spaces and the design of the small laths or battens, termed dunnage, which are placed between the individual boxes. A study of the problem has suggested that a few large channels for air circulation would be considerably more efficient than a number of small crevices. The inspection was made under the guidance of Dr. A. J. Smith, who is carrying out the work under the auspices of the Department of Scientific and Industrial Research.

The Future of Coal.

In the course of an address on coal, delivered at the Sir John Cass Technical Institute on Monday last, Mr. Frank Hodges stated that features of the British coal trade which, for years past, had been hoped to be transient and fleeting, had come to be regarded as permanent and static. The shrinkage of output and *personnel* as between 1913 and 1932, revealing a decline in tons of output of 78,000,000 and a decline of persons employed of 340,000, was sufficient proof of the permanent contraction of the industry. He regarded 1930 as perhaps a representative year for the next decade, with an annual output of approximately 240,000,000 tons and the number of employed at about 900,000. The question on which the industry should concentrate was how to restore that 1930 level at remunerative prices, so that funds would again be available for further technical developments and wages and profits. The importance of technical efficiency could not be exaggerated. Electricity and gas would, he thought, continue their inevitable march, but coal was their fundamental raw material. Foreign oil was coal's real enemy, and the one which should be attacked over the next decade with the utmost technical and scientific vigour. He urged a mass research attack on the whole problem of scientific coal utilisation. That, he suggested, was a surer road to travel than the apparently unfruitful way of re-establishing British coal in world markets.

The Fireproofing of Timber.

In connection with a visit made by members of the British Association on Wednesday, September 13th, to the Market Bosworth works of the Timber Fireproofing Company, Ltd., Mr. J. H. Narbeth gave an account of the present position with regard to the fireproofing of timber and particularly mentioned the progress made with the Oxylene process. A demonstration of the fire-resisting qualities of Oxylene-treated wood and a new fire-resisting fabric termed Boram was made. In the course of his remarks, Mr. Narbeth dealt with the testing of the fire-resisting qualities of wood and fibrous materials and the use of an ignition test value obtained by igniting the gas from a wood specimen, also the open and the closed burning tests. Mr. Narbeth gave figures for various kinds of untreated wood, which showed that fir was slightly superior to mahogany and oak and slightly inferior to red pine, while Oregon pine competed with teak for the superior position. For teak the typical results obtained were, in degrees Centigrade:—Flash point of the gas from the wood, 250 deg.; closed combustion point, 290 deg.; and open combustion point, 470 deg. Reference was made to the use of Oxylene-treated wood by the Admiralty and the Royal Air Force and on large liners, and to the work done by the Marine Department of the Board of Trade, the British Standards Institution, and the Fire Officers Committee.

The Late Sir Alexander Glegg.

By the death of Sir Alexander Glegg, which took place at his home, Princes-road, Wimbledon Park, on Tuesday, at the age of eighty-five, we lose an eminent engineer and business man, who, in his later life, was closely identified with the civic life of London and with wide religious and philanthropic interests. Alexander Glegg was born at Stonehaven, near Aberdeen, and received his education at the Gymnasium, Old Aberdeen, and Aberdeen University. He was trained as a marine engineer and came to London, where he spent some time in the drawing-office at Woolwich Arsenal. On leaving Woolwich he played some part in the designing and perfecting of the Hoe-Webb printing press. Later he became proprietor of Bowen and Co., Ltd., brassfounders, and did pioneer work in introducing to this country cast aluminium cooking vessels. He was a director of the Linoleum Manufacturing Company, Ltd., and later its chairman. He was also chairman of Barry and Staines Linoleum, Ltd., and a director of Barry, Ostlere and Shepherd, Ltd., and John I. Thornycroft and Co., Ltd. For some time he held the chairmanship of the Linoleum Manufacturers' Association.

The Shipping, Engineering and Machinery Exhibition at Olympia.

No. III.

(Continued from page 253, September 15th.)

B. J. HALL AND CO., LTD.

THE exhibit of B. J. Hall and Co., Ltd., of Stourton House, Dacre-street, London, S.W.1, provides clear evidence of the great advance which has been made in recent years in the design and production of engineering drawing-office equipment and material. The exhibits on the stand have been chosen as far as possible to illustrate the efforts made by Mr. B. J. Hall and his staff to help the designer and inventor to express their ideas easily and happily. In 1896 Mr. Hall invented the electric copier, and turned from civil engineering to devote his energies to further drawing-office improvements.

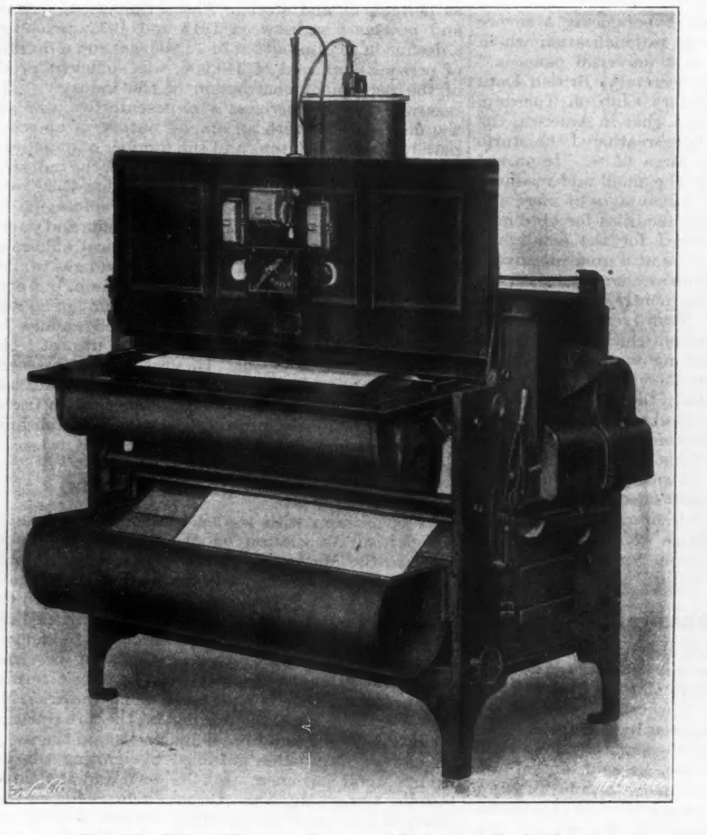

FIG. 53—"HALL-MARK" COPYING MACHINE—B. J. HALL

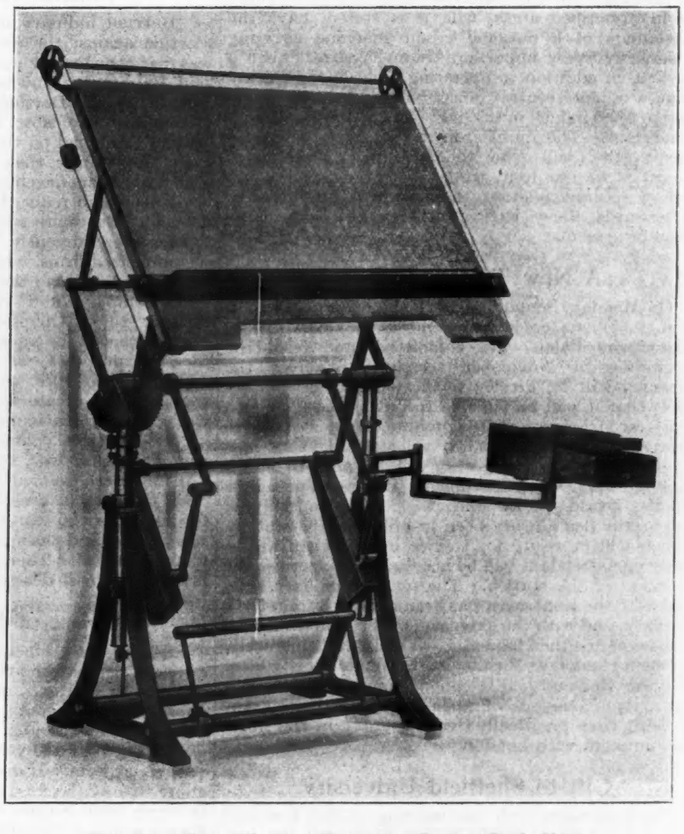

FIG. 54—"HALL-MARK" DRAWING TABLE—B. J. HALL

The vertical electric copier which may be seen, in almost its original form, on the stand supplied the first practical form of electric photographic plan copying in the world. It was not long before the vertical copier was followed by a continuous copier through which the print and tracing were carried on an endless band. Both the Hall-Mark (illustrated in Fig. 53) and the Sterling copiers are shown, together with the latest methods of development.

In the drawing-office itself great improvements have been made, and the "Hall-Mark" table illustrated in Fig. 54, is a new design, which embodies essential rigidity with single foot-pedal control, both vertically and horizontally. Moreover, it is so designed that alterations of angle do not cause either the board or the counterweights to require a working area in excess of the dimensions of the board and stand, an important feature when drawing-office space is restricted.

Another exhibit consists of sheets of the "R C" brand of tracing cloths, the newest of which is Mansfield pencil cloth. Since this cloth was introduced a little more than a year ago, engineers and architects are finding that, by using it, they can frequently eliminate tracing altogether. The surface is prepared so that a dense black line can be obtained with a pencil. It can, moreover, be erased without spoiling the surface of the cloth, either by hand or with an Ariel electric erasing machine, which has been designed to remove even Indian ink or printing ink without injury to a reasonably hard surface.

A view of the Ariel machine is reproduced in Fig. 55. It is supplied with a universal motor, for either A.C. or D.C. current at pressures of 200 to 250 volts, while 100 to 150-volt supply can be used in special cases. It only weighs 24 oz. complete, and is started and stopped by the switch on the outer casing just above the handle.

Referring further to the use of pencil tracings, it may be stated that before going to the print room, a pencil tracing is fixed by being wiped with a prepared fluid, and in this condition it is claimed that it has the same permanence as an inked tracing. The firm also supplies a blue-print paper giving extra contrast—Ferrograph—for use with its pencil cloth, so that the prints will have the same sharpness as prints made from inked originals.

Another interesting exhibit is the Protector binding machine for the edges of tracings, which was fully described in our issue of November 25th last year. The binding machine puts a double strip of strong linen round the edges. The tracing is simply wound through the little machine, no heat is used, and no special skill is required.

Brief reference may also be made to the Radioscript reproduction process, which is an interesting development of commercial photography for engineering work. Actually the method employed is not so much a process as a body of skilled men who can reproduce a drawing, a blue print, or any opaque original, either to the same size or to any larger or smaller size which is required. The copies can, if necessary be reproduced on translucent material, so that photoprints can be made from them in the same way as from a tracing. The examples displayed, which include some reproductions from the pages of THE ENGINEER, suggest the use of this process for making neat sets of reduced designs for convenient reference in an office or board-room.

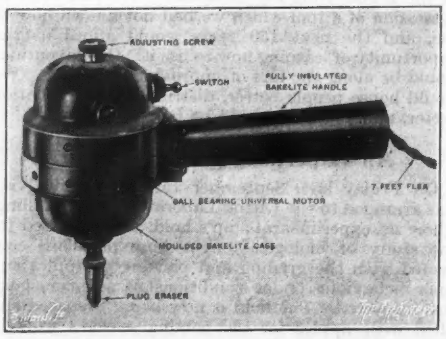

FIG. 55—ARIEL ELECTRIC ERASING MACHINE—B. J. HALL

THE BRITISH OXYGEN COMPANY, LTD.

Besides the exhibits described in a Supplement to our issue of September 8th, the British Oxygen Company, Ltd., is exhibiting two small compressors, one for air pressures up to 3000 lb. per square inch and the other for gas pressures up to 150 atmospheres, both of which are illustrated in to-day's Supplement.

The air compressor is a standard four-stage, two-crank, trunk type machine, with a maximum output of 70 cubic feet of free air per minute, and is one of a series. The crank case is totally enclosed, and all moving parts are pressure lubricated. Centrifugally cast renewable liners are fitted in the cylinders; the air valves are easily accessible, and since the suction and delivery valve for each stage are combined into a single unit, both valves can be removed and inspected at one operation. Careful attention has been given to the cooling of the air between stages. The first stage intercooler is of tubular form and is built into the frame of the machine, while the second and third intercoolers and the after coolers are coils immersed in the cooling tank surrounding the top cylinders. A final separator for removal of oil and water purifies the delivery air. The machine has been built especially to meet the demand for a moderately priced high-class compressor for use in connection with high-pressure work, and for small oxygen plants.

The gas compressor, which we illustrate in the Supplement, Fig. XIV., is the smallest of a standard range of machines manufactured by the company for high-pressure gas compression. It is a two-crank type, and compression is effected in two stages. All the motion work is totally enclosed and is very simple. The cylinder lubrication is effected by water which is an essential for maintaining gas purity. This machine has been specially constructed for dealing with small volumes of gas, and is designed to compress to a working pressure of 150 atmospheres. It is also suited for the compression of rare gases used in laboratories, &c., and for filling oxygen and other gas cylinders.

PERMAN AND CO., LTD.

We illustrate in Fig. 56 the first British Kromhout marine oil engine to be built in this country by John G. Kincaid and Co., Ltd., under the agreement with Perman and Co., Ltd., recently announced in our columns. The second engine, we are informed, is now approaching completion, and will shortly be delivered for use in one of the new motor vessels of Coast Lines, Ltd. As Fig. 56 shows, the Olympia engine is a three-cylinder model, complete with a hand-operated reversing clutch, but all engines over 200 B.H.P. are reversed by compressed air. It has a designed output of 150 B.H.P. at 320 r.p.m., with a cylinder bore of 265 mm. and a stroke of 350 mm.

The engine operates on the two-stroke cycle, with crank case compression and airless fuel injection, and is started by compressed air, a small air compressor being mounted at the clutch end of the engine on the bridge casting of the reverse gear. The same position on the engine has been chosen for the plunger type bilge and circulating water pumps, which are arranged at the two ends of the bridge casting. The mechanical lubricators are driven from the crank shaft and are placed near to the clutch. A feature of the engine is the heavy scantlings of both engine and clutch, which are specially designed for marine service, with, if necessary in the case of some of the smaller ships, unskilled attention. The question of easy accessibility has been kept in mind, and each cylinder can be dismantled without having to break the joints and pipe connections of the others. The three-part jointing of the exhaust pipe to facilitate this may be noted. Other features of the engine include the patented Kromhout roller plate gudgeon pin, and the grouping of the fuel pumps, starting cams, and governor with its controls, on a vertical shaft drive at the fly-wheel end of the unit. The engine is supplied with pressure lubrication, both to the main bearings and the clutch gear, and mechanical lubrication for the main cylinders, the system including oil filters and a large oil cooler. The rated fuel consumption is 0·40 lb. of oil per B.H.P.-hour, with a ten per cent. tolerance. When the engine has been run in, after, say, running in daily service for a month or six weeks, the consumption of lubricating oil works out at about 0·005 lb. to 0·006 lb. per B.H.P.-hour.

The engine is furnished with ball bearing thrust blocks, which take both ahead and astern thrusts, and which are lubricated by wick type oil feeds. In the case of the larger engines, which are reversed by compressed air, a Michel pattern of thrust block is used. Although the engines we have described are manufactured by Messrs. Kincaid, the sole selling rights are in the hands of Perman and Co., Ltd., which firm also provides installation and maintenance facilities and spare part service at its Bermondsey service department.

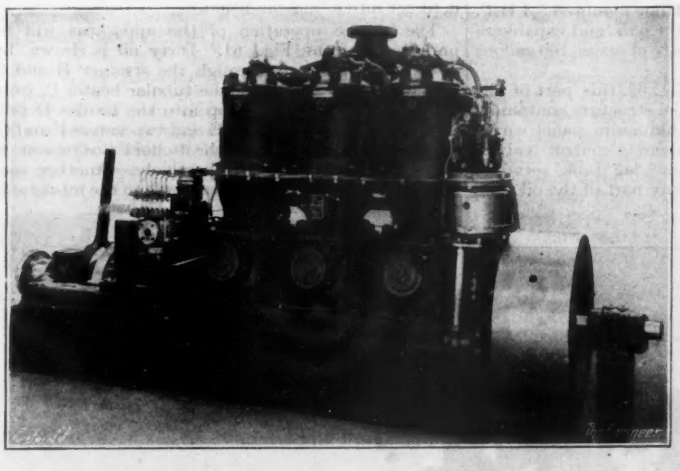

Fig. 56—150 B.H.P. British Kromhout Oil Engine—Perman

THE JOHN THOMPSON ASSOCIATED COMPANIES.

A large exhibit on the stand of the associated companies of John Thompson, Ltd., of Wolverhampton, comprises the fusion welded boiler drum and dished end illustrated in Fig. 59. The thickness of the plate is 1½in. and the designed working pressure 750 lb. per square inch. The firm has specialised in electric and water gas welding for many years past, and has evolved a welding technique which it claims is outstanding in British boiler engineering service. The electrodes used are manufactured by the firm itself, from a formula which has been found particularly suitable for large boiler work. The shielded arc system is used, and the method employed has been arranged to deposit the minimum amount of slag, thereby avoiding inclusions in the weld.

The machine, which has been recently installed for this very special work, is designed for a range of ampères up to 1000 with a corresponding graduation of voltage. With this machine the speed of welding has been advanced to many times more than that of the older type of machine, and the efficiency of the weld has been increased. The test pieces exhibited have, in many cases, shown an elongation up to the maximum, and have broken in the solid plate leaving the weld intact.

The dished end illustrated in Fig. 59 is an example of the firm's press work, which is done in a range of presses up to 3000 tons capacity. Water gas welding is also a speciality of the firm, and examples of water gas welding are provided by two types of marine furnaces, in which the weld is both corrugated and flanged. The John Thompson patented annealing cover—Fig. 57—also illustrates a typical water gas weld. The cover is made from a plate equal in length to twice the depth of the pot plus the length of the bottom, and in width equal to the width of the pot plus the width of one side. At the appropriate positions near the centre of the length of the plate two deep right-angled notches are cut opposite each other on each side forming a W contour. The sides are then flanged in at right angles, and on lines carried through the bottoms of the notches, and on bending across two transverse lines joining the bottoms of the notches, the plate edges meet in a Y, which is welded, thus forming a rectangular vessel. This special one-piece welded construction has been chosen because, when inverted in the furnace covering the parts to be annealed, the flames of the furnace sweep over solid metal corners giving a longer life to the cover.

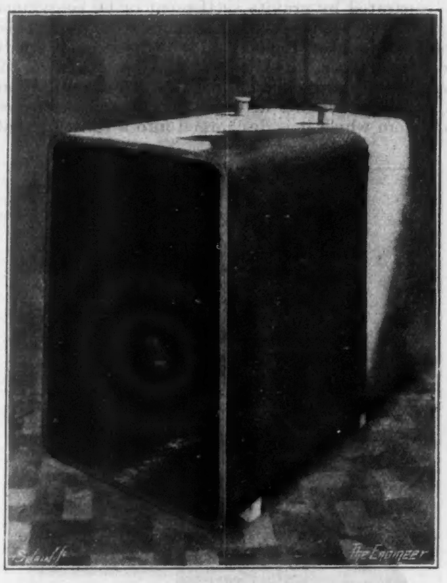

Fig. 57—Gas-Welded Annealing Cover—Thompson

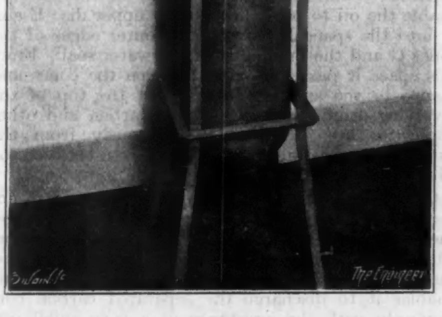

Fig. 58—Dejector Scale Preventer—Thompson

Another welded vessel illustrates the work of the firm's chemical and general engineering department, and is a mild steel pan homogeneously lined with lead. Such lead-lined vessels have been constructed in diameters up to 13ft. and 16ft. in height without creepage, and to withstand the action of acids under pressure, vacuum, and high-temperature conditions, which, even two years ago, would have seemed too severe. Similar work includes special antimony and lead linings for vessels, pipes, and coils. The lead linings referred to have been applied to cast iron, bronze, copper, and Monel metal articles. A stainless steel vessel is also shown on this stand. It illustrates the recent development in this particular metal and its electrical welding, which is carried out by the Dudley branch of the firm. The welding technique for stainless steel has now been so far developed by John Thompson that supply pipes, and vessels of considerable dimensions, can, we are informed, be constructed from, or lined with, 16 gauge or even 18 gauge stainless steel. This department also specialises in the jacketing of stainless steel vessels with mild steel, and the lining of mild steel vessels and wooden vats with stainless steel. Though not shown at Olympia, vessels made in British-made nickel-clad steel by the firm are also among the very latest examples of chemical and industrial engineering practice.

Other exhibits include an example of the John Thompson vertical economic boiler adapted for marine work. The firm's boiler plant production also includes a simple form of steam trap, the copper-nickel balls of which are true to 0·003in., an indication of the accuracy required in modern boiler work. Other sections of the stand have been designed to display the Kennicot pressure-type of water softener, a 3ft. diameter example of which is shown. It is designed to work at 75 lb. per square inch. The base exchange material used is a natural non-porous mineral, "Kenzelite," which has a high resistance to disintegration. Common salt is used as the regenerative agent.

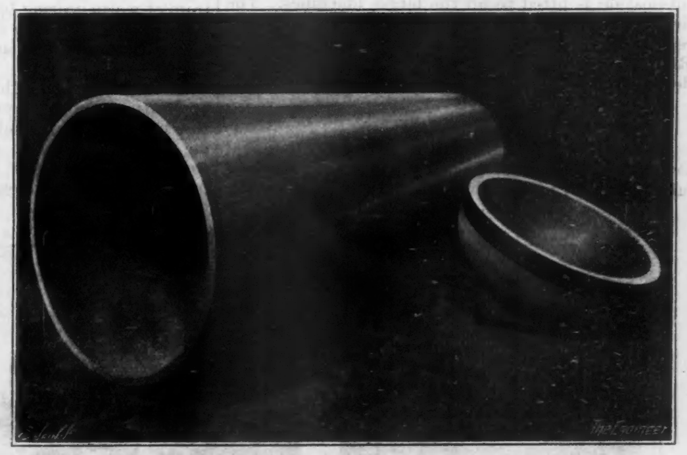

Fig. 59—750 Lb. Pressure Fusion Welded Drum—Thompson

In Fig. 58 we illustrate the Kennicot patented Dejector purifier, which is a simple apparatus designed to keep steam boilers free from mud and scale. The boiler water is continuously circulated through the Dejector, which delivers a controlled dosage of soda ash solution. The circulation is so arranged by means of a central down tube and a baffled upward flow that the precipitated hardening salts and suspended matter are continuously removed from the water and deposited in the Dejector, from which they can be blown off at intervals. The apparatus illustrated is made in various sizes to suit different boiler capacities, and is used for railway locomotives, marine boilers, and oil field work.

J. AND E. HALL, LTD.

The stand of J. and E. Hall, Ltd., of Dartford Ironworks, Kent, is noteworthy in that, for the first time, three new designs of CO_2 and ammonia gas compressors are shown. They are all illustrated in to-day's Supplement. The largest exhibit—see Fig. VI.—is a marine type horizontal twin enclosed single-acting CO_2 machine, which has been specially designed for high-duty service on modern meat-carrying vessels, and is electrically driven by a motor coupled to the fly-wheel shaft. The machine may, however, also be driven by an oil engine or steam engine and provision is made for bolting the prime mover base-plate to that of the compressor. The balanced crank shaft is of the solid pattern, machined from a single forging, and white metal lined bearings are used. The connecting-rods are of the marine type with split adjustable bearings both at the crank pin and forked crosshead ends. The crank pin brasses are white metal lined, while phosphor-bronze bushes are used on the crosshead ends. The forced lubrication system is complete with an Auto-Klean strainer on the suction side and a pressure gauge and relief valve on the delivery side. In order to supply pressure oil to the compressor glands a special hand pump is used. Both the compressor glands and the pistons are furnished with metallic packings. As our illustration indicates, the whole of the motion work is enclosed within light steel covers, the front half cover being removable for inspection purposes. The gas headers and the top valve boxes are all machined from solid steel forgings. This machine is of the new type now being supplied for motor cargo liners now under construction in the North of Ireland. Another CO_2 compressor is the twin single-acting machine illustrated in Fig. VII., which is arranged for working with intermediate liquid cooling, but can also be built to operate on the simple CO_2 compression cycle. It is specially suited for high-speed driving either direct or with a belt. In the usual arrangement the cast iron base-plate of the refrigerating machine and its motor is utilised as a casing for the condenser coils, thus forming a self-contained high-pressure side of the unit. The machine follows the maker's standard practice in the construction of valves and moving parts, and a feature in the design is the use of roller bearings and a ball type thrust bearing. This machine is particularly useful for ships' provision rooms and similar duties.

In Fig. IX. we illustrate a twin-cylinder vertical single-acting ammonia compressor arranged for V belt driving. The crank case and outer bearing form one casting and there are large inspection doors. The pistons are of the double trunk pattern with pressure rings in the top and bottom portions and an oil scraper ring and groove in the bottom portion. The suction valve is of the poppet type, arranged in the top of the piston, while the poppet discharge valves are on the safety head of each cylinder. The suction and discharge manifolds, are all in one casting. This embodies both the suction and the discharge stop valves, together with by-pass and pumping out valves. There is an easily removed strainer on the suction side of the manifold, together with an excess pressure safety device on the high-pressure side, which in a case of emergency will relieve the pressure back to the suction side. In the smaller sizes of these compressors splash lubrication is employed, but forced lubrication is fitted to all the larger machines. The firm is also showing a range of " Hallmark " automatic refrigerating machines, which enjoy a wide use in the Royal Navy and also in British and foreign mercantile fleets.

J. Stone and Co., Ltd.

The principal exhibit on the stand of J. Stone and Co., Ltd., of Deptford, S.E.14, is a new self-contained oil purification plant, which enables colloidal carbon to be removed continuously in the centrifuge without the use of chemicals. The Stone Empson process is based on the discovery that water properly atomised in an oil containing colloidal carbon acts as a perfect coagulant and its action is to neutralise the electric charge carried by the carbon particles and thus to stop the " Brownian movement " to which they are subject and which interferes with precipitation. The process is carried out in the Colloid Coagulator, which atomises the added water in the oil, after which the neutralised carbon particles rapidly coagulate into comparatively large clots, which can then be separated by gravity settlement or by centrifugal means. The Colloid Coagulator consists of a small disc rotor running at 10,000 r.p.m. It is provided with vortex passages, which create turbulence between the liquids and ensure the desired degree of atomisation. A detachable casing in which the liquid is collected and from which it is discharged into a time lag tank surrounds the rotor, which is driven through a single train of worm gearing by a " flange mounted " 1 H.P. electric motor running at 2800 r.p.m. and capable of operating the machine at the rate of about 100 gallons of dirty oil per hour.

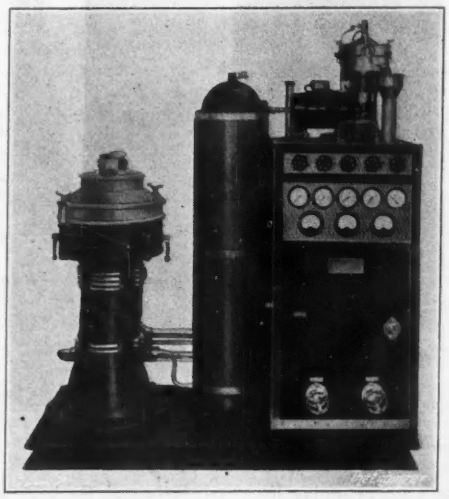

Fig. 62—Oil Purifier—Stone

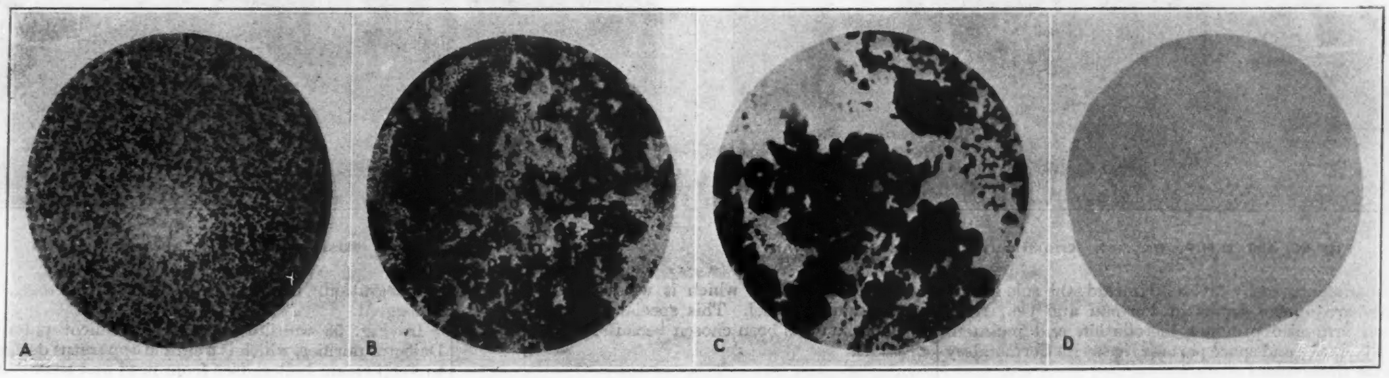

Fig. 60—Photo-Micrographs Showing the Effect of Oil Purification Process

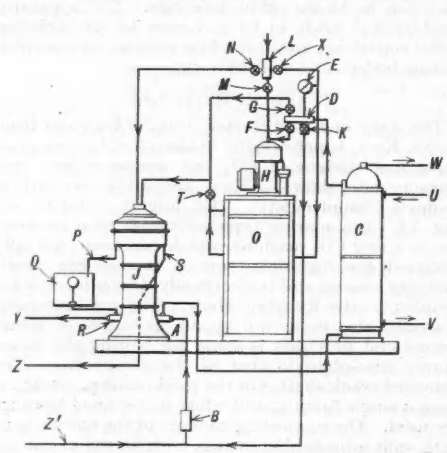

Fig. 61—Arrangement of Oil Purifier

As shown on the right of Fig. 62, this part of the apparatus is mounted on a steel structure containing the time lag tank and an aluminium panel carrying all the necessary instruments, control valves, &c. Baffles fitted in the time lag tank serve to prevent the direct passage of any part of the oil from the inlet to the outlet, and thus ensure a few minutes' delay for the agglomeration of the neutralised carbon particles.

From the tank the oil passes to the Ultra Centrifuge, to be seen on the left of Fig. 62. This machine has been designed to deal with oil in the condition described and has a preliminary separating space A —Fig. 63—inside the revolving drum, which enables the more readily separable particles of water and clots of carbon to be discharged direct to the walls of the drum without being re-mixed with the oil, which passes over the inner edge of a horizontal baffle B immersed at its outer periphery in the water seal C. Separate channels D are provided in this disc to enable the oil to pass through the upper disc E and so into the space F between the outer edges of the cones G and the inner side of the water seal. From this space it passes inwards between the cones and thence to the annular outlet H at the top of the revolving drum, while the water, carbon and other impurities are discharged continuously from the outlet I, the distribution of oil being even between the whole of the cones.

Contrary to the usual practice, the cones are not perforated, and as the oil enters from the outer edges the whole area of the cones is used for separation, which is mainly effected in the zone of the highest centrifugal force. The construction of the drum enables it to discharge the separated carbon continuously with the assistance of a very small percentage of hot water admitted with the incoming dirty oil, and the machine can run for very long periods without stops for cleaning. Provision has, nevertheless, been made for the convenient handling of the drum when, for example, this becomes necessary in order to change over from one kind of oil to another.

The motor and driving mechanism form an integral part of the frame and the high-speed drum spindle passes through the hollow motor shaft and is driven by a train of gearing with an automatic clutch which relieves the load on the motor when the machine is starting. This train of gearing also drives one of two oil pumps as required, the pumps being compactly fitted in the gear-box and easily detachable for inspection. Automatic lubrication is employed throughout. In the case of the apparatus exhibited the oil heater to be seen in the centre of Fig. 62 is steam heated, but when the apparatus is used in a sub-station or in any other place where steam is not available an automatically controlled electric heater is supplied.

As internal combustion engine oils frequently contain lighter volatiles, which should be removed, the dome cover of the heater is fitted with a patented automatic relief valve, which discharges any accumulation of gases, and where this discharge is appreciable a condenser may be fitted to recover the volatile fraction. Each centrifugal machine is provided with an electrical tachometer on the instrument panel, which also carries an indicator for showing the amount of oil in gallons per hour passing through the Colloid Coagulator. All the controls have been centralised with a view to facilitating operation.

The amount of water used in the colloid coagulator is rarely above 1 per cent. of the oil being treated and is said to be completely removed by the ultra centrifuge. With the apparatus oil that has been in service for such a long period that it had to be condemned has been restored to a brilliant condition and perfectly fit for further service. Instead of allowing the coagulated oil to pass to the ultra centrifuge it may be led to settling tanks; but, needless to say, this greatly adds to the time required for the purifying process. Users of the apparatus are recommended to treat the first supply of clean oil and never to allow it to get into a bad condition.

The precise operation of the apparatus will be understood from Fig. 61. Dirty oil is drawn by means of a pump A through the strainer B and is forced into the bottom of the tubular heater C, from which it emerges at the top into the header D provided with a thermometer E and two valves F and G, which communicate with the Colloid Coagulator H and Ultra Centrifuge J respectively. Another connection from the header passes back to the intake side of the strainer through a relief valve K, thus enabling the flow to either machine to be regulated on the pressure side by means of the valves mentioned.

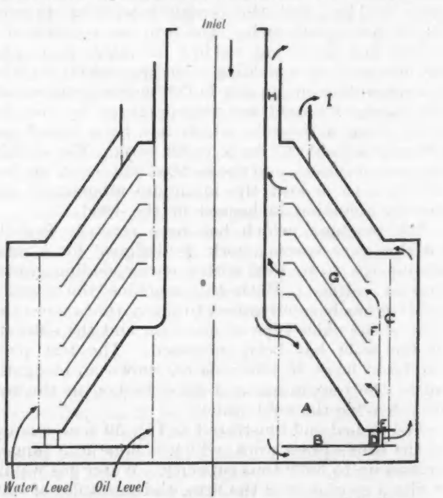

Fig. 63—Diagrammatic Section of Ultra-Centrifuge—Stone

Hot water derived from any convenient source is supplied to the header L, from which it passes to the Colloid Coagulator and ultra centrifuge by means of the valves M and N respectively. From the heater the oil passes through the Colloid Coagulator H into the tank O and over into the Ultra Centrifuge J, where it is separated from the carbon, water and other foreign matter and then discharged through the pipe P to the tank Q, which contains a float-operated valve communicating with the suction side of the pump R, the function of the valve being to maintain a certain head of oil so that any entrained air is released whilst no air can be drawn through the pump to cause frothing in the discharge pipe.

The pump R delivers the clean oil back to the engines or storage tanks, while the separated water and dirt are discharged from the Ultra Centrifuge at S. Provision is made for running the latter without the coagulator, which can be brought into service whenever the oil shows signs of blackening. In such cases the output of the apparatus can be raised to 250–300 gallons per hour. Under these conditions the valves F T are closed and the valve G opened, thus allowing the dirty oil to pass direct from the heater into the centrifuge. The steam supply to the oil heater enters at U, a trap being provided at V to drain away the condensate. The gas relief valve is indicated at W, whilst X is the valve which serves for feeding hot water into the time lag tank O to float off the remaining oil into the ultra centrifuge when stopping the plant. The pipes shown at Y, Z, and Z^1 serve respectively as the clean oil delivery, the waste to bilge, and the dirty oil inlet. An analysis of internal combustion engine oil before and after treatment is given below.

	Before.	After.
Carbon	2·5%	Nil
Water	2·9%	Nil
Acidity (in terms of SO_3)	0·21%	0·07%
Specific gravity at 60 deg. Fah.	0·924	0·905
Viscosity Redwood at 70 deg. Fah.	2048 secs.	1526 secs.
Viscosity Redwood at 100 deg. Fah.	687 secs.	540 secs.
Viscosity Redwood at 140 deg. Fah.	219 secs.	184 secs.

The photo-micrographs, Fig. 60, illustrate the effects of the process. Dirty lubricating oil from internal combustion engines is shown at A, the same oil after coagulation at B, the carbon, &c., discharged from the oil separator at C, and the purified oil at D.

W. H. Allen, Sons and Co., Ltd.

Without doubt, one of the most attractive displays in the exhibition is that arranged by W. H. Allen, Sons and Co., Ltd., of Bedford, comprising, as it does, oil engines, steam turbines, steam engines, pumps, D.C. generators and motors, control gear, fans, &c., both for marine auxiliary and for industrial purposes. From the many interesting exhibits we have chosen one or two for illustration.

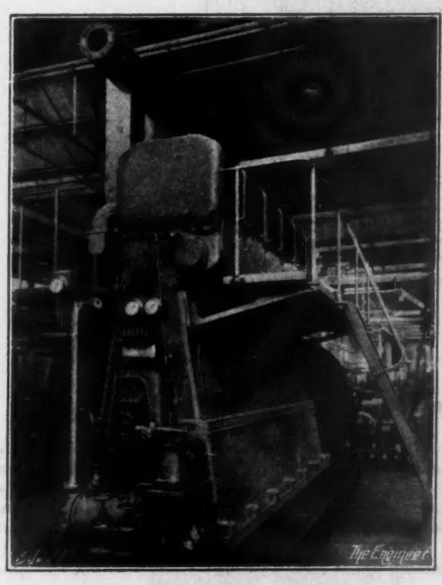

Fig. 64—550 B.H.P. Six-Cylinder Oil Engine—Allen

The largest oil engine is the six-cylinder unit illustrated in Fig. 64, which has a designed output of 550 B.H.P. at 350 r.p.m., the cylinder bore being 350 mm. and the stroke 470 mm. A smaller engine, which we do not illustrate, is the six-cylinder 150 B.H.P. unit, an example of the firm's steel construction giving low weight for marine and land transport purposes. The design features of these engines have been referred to in our pages from time to time, and we need not again describe them.

A new engine designed for marine propulsion work is illustrated in Fig. I. of to-day's Supplement. It is a four-cylinder, 134 B.H.P. engine running at 500 r.p.m. with a bore of 230 mm. and a stroke of 300 mm. It is complete with auxiliary water pumps and a compressor for starting air. A feature of this engine is the neat form of reverse gear. It consists of a drum incorporating nickel steel bevel pinions, which mesh with a driving wheel on the crank shaft extension and with a driven wheel on the reverse shaft. On the other side of the brake drum is mounted a plate type friction clutch housing, the main clutch member forming part of the reversing shaft. A cast iron contracting brake is mounted on the drum, the contracting mechanism being interconnected with the lever operating the plate clutch. With the manœuvring lever in the vertical position, the clutch is disengaged and the brake free. The drum and clutch housing are free to rotate in the same direction as the crank shaft, the reverse shaft being stationary. When the lever is moved to the ahead position the plate clutch is engaged, locking the clutch housing and drum solidly with the driven wheel and reversing shaft; thus the driven wheel and pinions cannot move relatively. The whole unit is, therefore, driven in the same direction, and at the same speed as the crank shaft, the load being transmitted through the clutch. When the manœuvring lever is moved to the astern position, the plate clutch is released and the hand brake contracted, gripping the drum and holding it stationary. The pinions are now free to rotate and transmit the drive from the crank shaft wheel to the driven wheel and reverse shaft in the "astern" direction. A thrust bearing is provided on the shaft within the gear case. This type of reverse gear is particularly well suited, it is claimed, for control from the bridge.

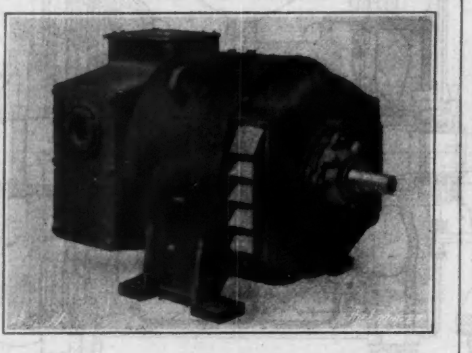

Fig. 65—D.C. Ventilated Drip-Proof Motor—Allen

The 50 kW turbo-generator illustrated in Fig. X. in the Supplement is designed for auxiliary purposes on board ship, or for use as a pilot set in conjunction with a large turbo-generator set. It is of the single-stage impulse type. The speed governor is of the centrifugal type, and is driven by a vertical shaft at the steam end through a worm and wheel, the governor operating the throttle valve through an oil relay.

The reduction gear incorporated in the design is of the single helical type, with the pinion made integral with the turbine rotor shaft. The turbine has been designed to exhaust against a vacuum or back pressure, and a hand valve is provided to enable it to operate economically under the different exhaust conditions.

The turbine-driven axial flow pump, shown in the Supplement, Fig. XI., consists of a single-stage impulse turbine direct-coupled to the pump, and is a typical example of modern practice in respect of main circulating pumps.

The pump casing and rotor are constructed from highest quality gun-metals with a forged bronze shaft, an inspection door being provided to give ready access to the moving parts without disturbing the main pipe connections.

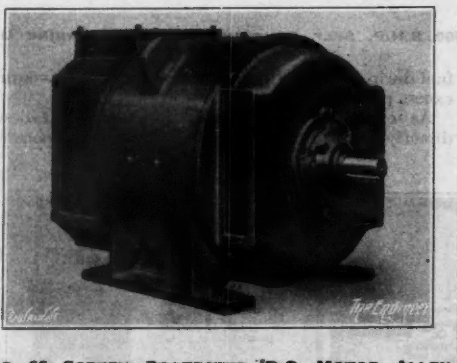

Fig. 66—Screen-Protected D.C. Motor—Allen

The electrical exhibits consist of D.C. generators and motors and control gear designed to meet Lloyds and other official requirements. Enclosed ventilated, pipe ventilated, and totally enclosed machines for vertical and horizontal operation, are shown. All the machines are built on robust lines, and all the internal parts can easily be inspected. The machine shown in Fig. 65 is a ventilated, drip-proof motor, and that in Fig. 66 a screen-protected motor. Ball and roller bearings are fitted as standard practice, but, if desired, sleeve-type bearings with ring lubrication are provided. The brushes are carried in non-ferrous cast boxes and provision is made for accurate brush setting. Mica is the basis of all the insulation, which is reinforced with other materials to avoid flaking.

The control gear exhibits consist of drum-type and automatic panels, designed on similar lines, for constant and variable-speed motors, and suitable for floor or wall mounting. The cases are composed of stout steel plates with easily removable hinged doors with inspection windows. All the panels are constructed on the unit principle. Starting is done in the case of the drum-type panels by the operation of a metallic drum with renewable copper contacts, the drum being turned by a hand wheel to be seen at the side of the panel shown in Fig. 67. A mechanical detent holds the drum in the "full on" position, but if it is released before the starting operation is completed, it is returned to the "off" position by a powerful spring. All the resistance units consist of non-corrodible alloy wire wound over suitable insulation on metal tubes, the starting units being rated on a one minute basis, and are proportioned to start the motor against full load torque. An electro-magnetically operated contactor switch makes and breaks the circuit. Failure of voltage or any other trouble that may lead to the de-energising of the operating coil causes the contactor to open, and owing to the provision of interlocks it cannot be closed again until all the starting resistance has been re-inserted. The overload trip, which is of the self-setting solenoid type with a time lag device, permits of adjustment between full load and 100 per cent. overload. To ensure that the circuit is always broken on the contactor, the double-pole isolating switch is interlocked with the contactor.

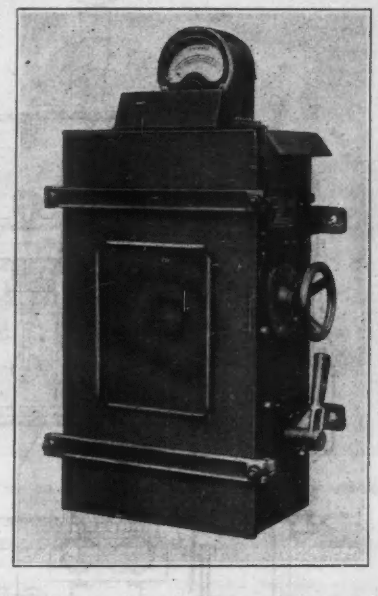

Fig. 67—Drum Type Starting Panel—Allen

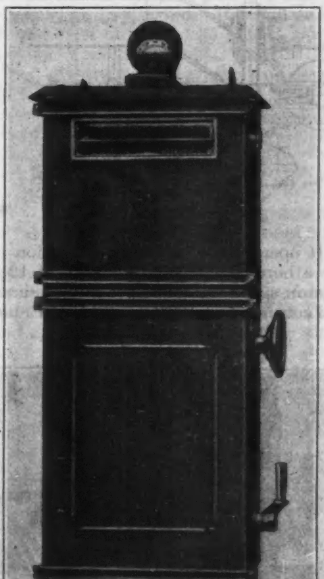

Fig. 68—Drum Type Variable Speed Controller—Allen

In the case of the variable-speed panels, as shown in Fig. 68, a shunt field regulator of the straight-line type, is screw-operated by an external handle, and is interlocked with the contactor operating coil to prevent the motor being started without full excitation.

The automatic panels comprise a number of electro-magnetic contactor switches and starting resistances, as used in the drum panels, the sequence and time of operation being controlled by a relay on each switch, independently adjustable for timing to suit conditions. Starting and stopping is done by push-buttons mounted on the case or at some remote point, or by control devices such as float or pressure switches.

Belliss and Morcom, Ltd.

The principal exhibit on the stand of Belliss and Morcom, Ltd., of Ledsam-street Works, Birmingham, is the 200 B.H.P. six-cylinder oil engine driven generator set illustrated in Fig. III. of to-day's Supplement. It operates on the airless injection principle, and has a bore of 8½in. and a stroke of 12½in. The mean piston speed is 1250ft. per minute, and the full load fuel consumption 0·39 lb. per B.H.P.-hour. The main features of this engine were described in The Engineer of February 17th, 1933, so that we only need to emphasise a few special points. Although a totally enclosed design has been adopted the light aluminium covers are easily removable. The cylinder head joints are subjected only to gas pressure, a separate water connection, which is easily accessible, being used between the cylinder and the cylinder head. An attractive feature is the single-wheel control gear, which provides for careful regulation of fuel during the starting revolutions, thereby avoiding excess pressures.

As exhibited at Olympia the engine is shown directly coupled to a Crompton-Parkinson generator.

Another important exhibit is the 1500 B.H.P. 4500 r.p.m., self-contained turbine, which we illustrate in Figs. 69 and 70. The condenser, which is of the firm's squat type, and will be seen in Fig. 69, is not exhibited at Olympia, only the bottom half casing of the turbine with the rotor and governor box being shown. The turbine is a sixteen-stage Rateau machine, designed for a steam pressure of 160 lb. per square inch, and 500 deg. Fah. steam temperature. The rotor blades are of stainless steel and Monel metal is used for the casing blades. A feature of the arrangement—see Fig. 69—is the centre suspension of the turbine unit to provide for expansion. The governor control gear conforms with Belliss and Morcom standard practice. Part of this gear is shown in Fig. 70, which illustrates the unit in course of erection in the maker's works. The drawing we reproduce shows the general lay-out of the vertical-spindle turbine-driven condensate pump. A separate motor-driven circulating pump is provided.

A small unit of unusual interest is the Midget horizontal turbine and condenser, illustrated in Fig. 71. It is coupled to a ½-kW generator by Higgs Motors, Ltd., of Witton; and works at 50 lb.

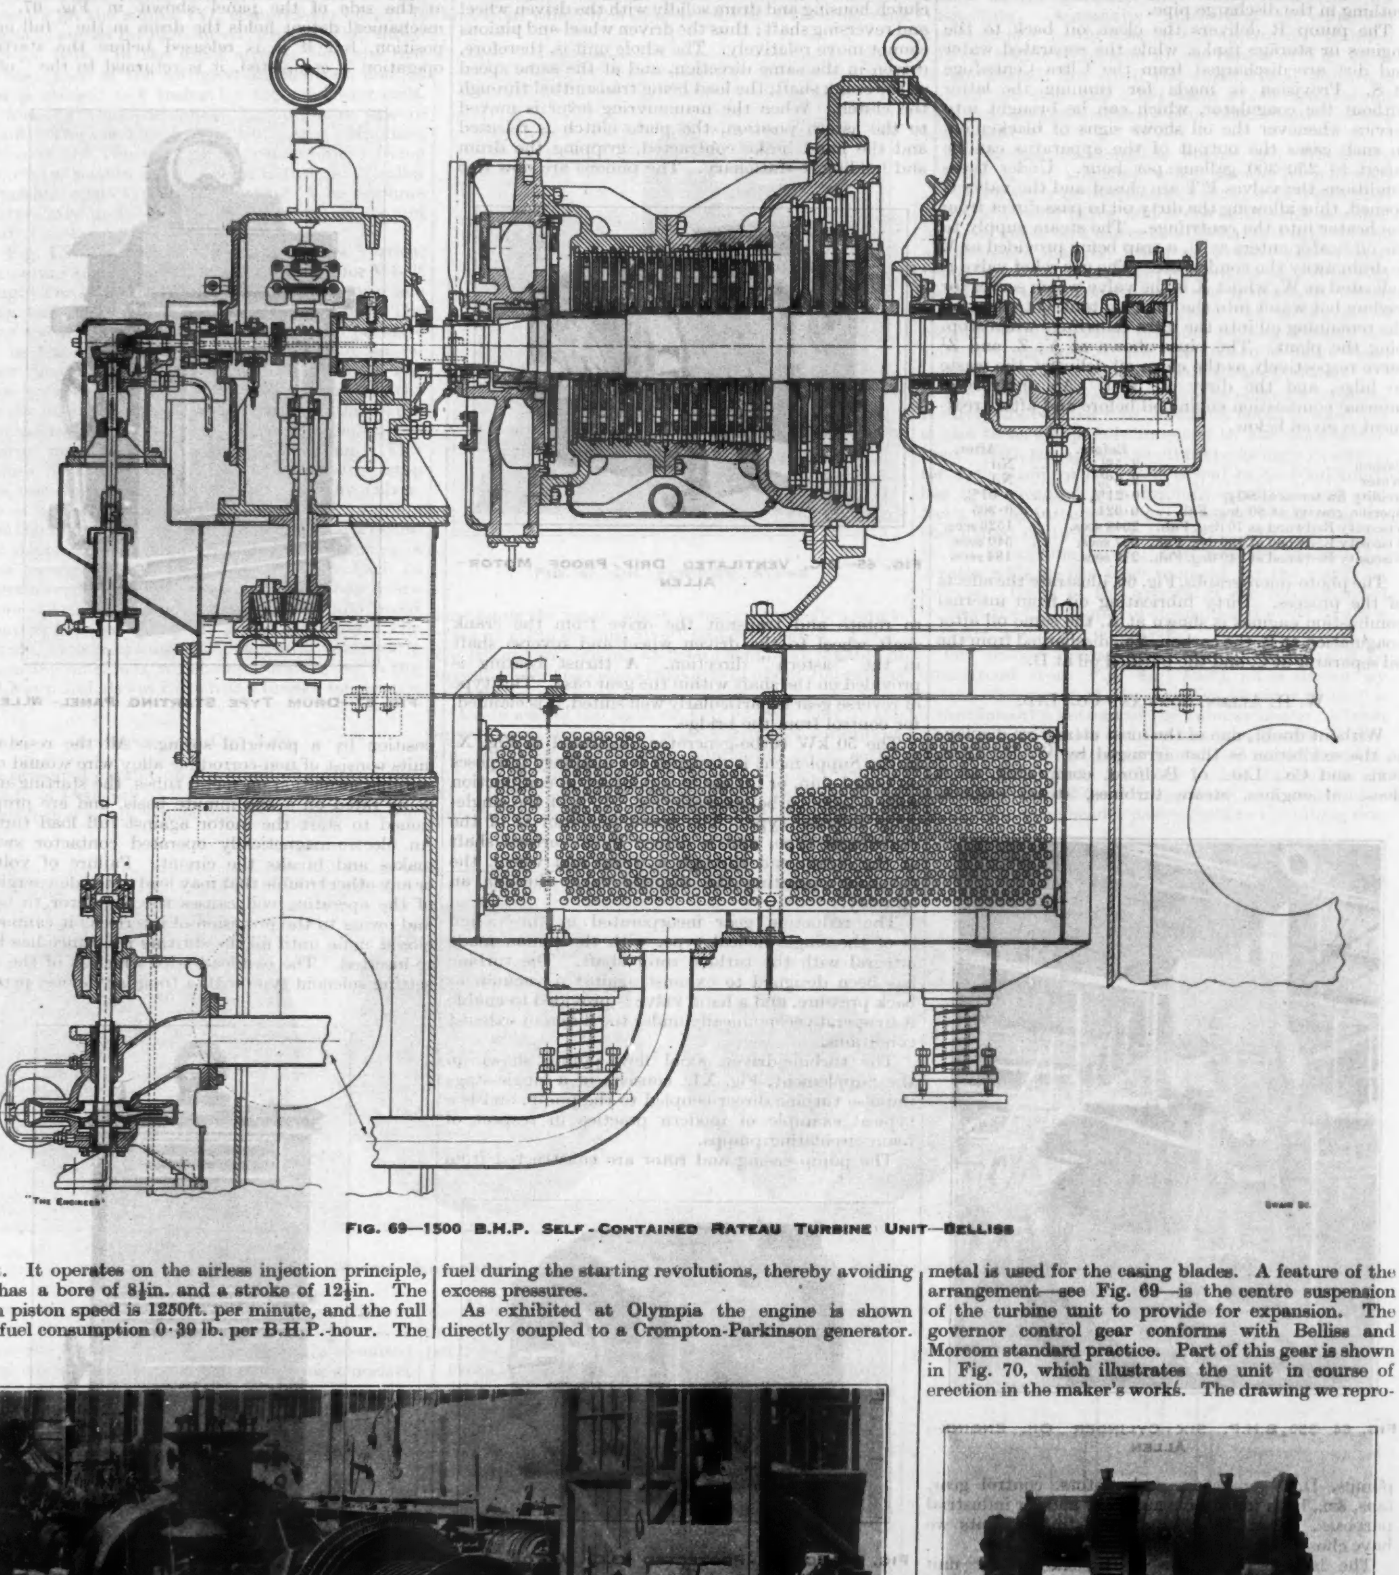

Fig. 69—1500 B.H.P. Self-Contained Rateau Turbine Unit—Belliss

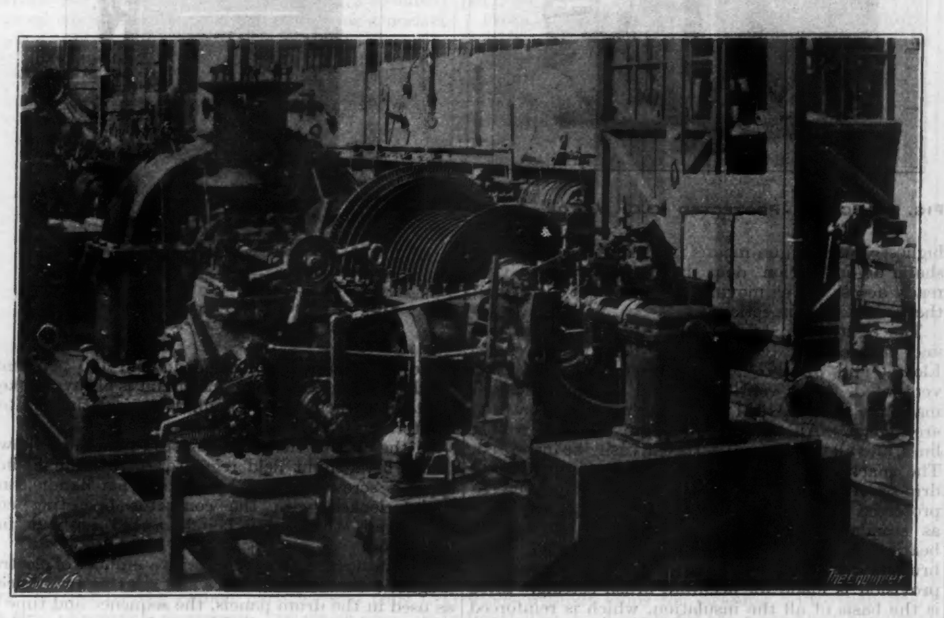

Fig. 70—Turbine in Course of Erection—Belliss

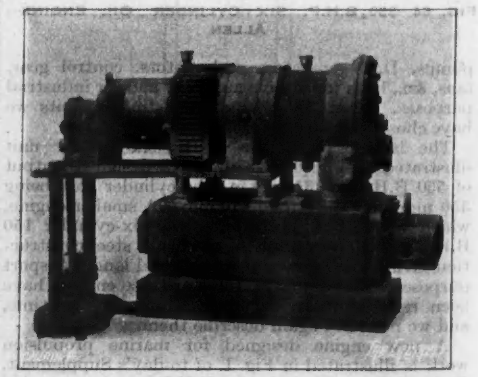

Fig. 71—"Midget" Turbo-Generator—Belliss

pressure, or with 100 lb. pressure an output of 4 kW is obtainable. The turbine is of the two-pass velocity impulse type, and is controlled by a Pickering type governor. The unit illustrated is complete with condenser and turbine-driven condensate pump, a separate supply of condensing water being assumed. The same turbine can be supplied in a vertical form, and the design is regarded as particularly suitable for locomotive lighting and industrial service. The Belliss and Morcom steam reciprocating engines are still in demand, and the firm is exhibiting a two-crank compound engine coupled to a 50-kW Crompton-Parkinson generator, which is one of two sets for a new G.W.R. steamer. On the same stand there is a display of Arca type regulators for boiler and industrial steam control, demonstrating the varied uses of this type of plant.

REAVELL AND CO., LTD.

A full and varied range of air-compressing plant makes an attractive exhibit on the stand of Reavell and Co., Ltd., of Ranelagh Works, Ipswich. One of the large exhibits is a 1000 cubic foot two-stage, two-crank, air compressor, with a 12in. H.P. cylinder and 21in. L.P. cylinder, and a stroke of 9in., which is of the same type as the 1500 cubic foot machine illustrated in Fig. 72, but is exhibited without a motor, along with a 500 cubic foot machine. These compressors are taken from a range extending from 400 cubic feet up to 5000 cubic feet at pressures from 120 lb. to 150 lb. per square inch, the machines being fitted when desired with automatic unloaders.

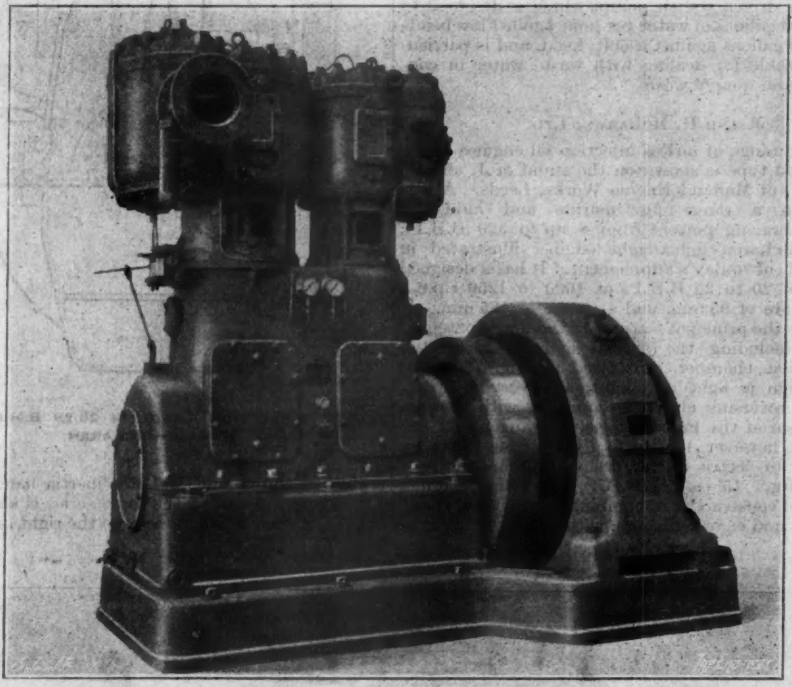

FIG. 72—1500 CUBIC FOOT MOTOR-DRIVEN COMPRESSOR—REAVELL

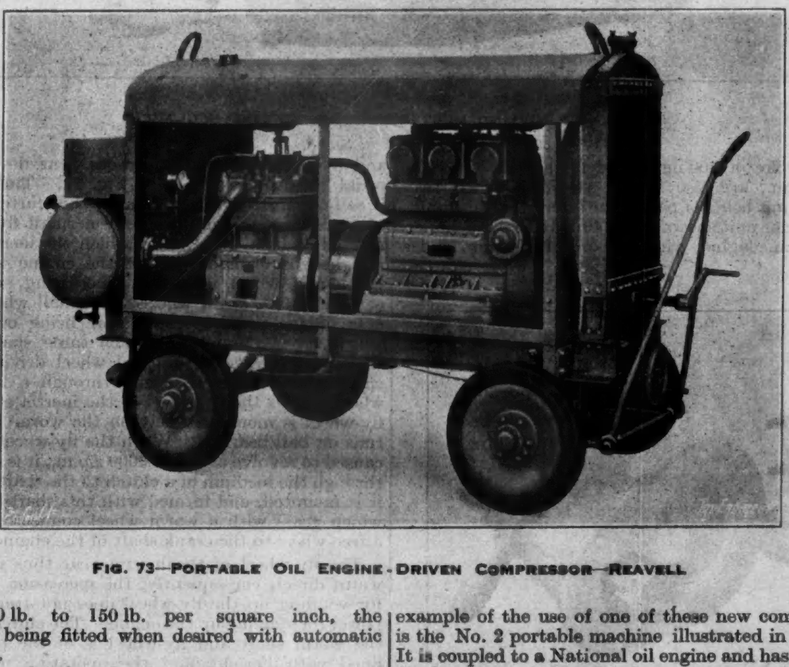

FIG. 73—PORTABLE OIL ENGINE-DRIVEN COMPRESSOR—REAVELL

The firm is also showing a complete range of vertical, two-crank, two-stage, water-cooled compressors for pressures of 450 lb. and 1000 lb. per square inch, which are employed for charging air bottles for starting internal combustion engines, for pipe and vessel testing, and similar uses. Another interesting group is composed of four machines taken from a range of eleven single-acting, single-stage compressors, giving a range of 200 to 300 cubic feet of free air per minute when delivering to a final pressure of 100 lb. per square inch. The smaller machine is air-cooled, but the others are water-jacketed, and a new model is the three-crank machine illustrated in Fig. VIII of the Supplement. It has a designed capacity of 300 cubic feet per minute. This same series of machines can quite well be used for vacuum purposes.

A new development in rotary, rolling, drum-type air compressors and exhausters is the water-cooled machine illustrated in Fig. 74, which is of the 8in. by 8in. size running at 115 to 1725 r.p.m., and designed for working pressures up to 30 lb. to 40 lb. per square inch. The use of a well-designed water jacket has enabled the pressure to be increased from 20 lb. up to nearly double that pressure. The range is manufactured in capacities from 25 up to 2000 cubic feet of free air per minute.

Several exhibits on the stand illustrate the new single-stage, twin-cylinder machines with piston-type suction valves, which are designed for portable compressor work and run at 1000 r.p.m., delivering air at 100 lb. per square inch. A full description of this machine was published in THE ENGINEER of December 9th, 1932, when a description of the patented unloading valve was also given. An example of the use of one of these new compressors is the No. 2 portable machine illustrated in Fig. 73. It is coupled to a National oil engine and has a piston displacement of 118 cubic feet per minute, delivering air at 100 lb. pressure. The compressor will serve two to three of the firm's new B.A.L. type "John Bull" concrete breakers. Mention should also be made of the interesting range of five small rotary-type machines, suitable for working pressures up to 15 lb. per square inch, and vacuums of 20in. mercury. These have been introduced to meet the growing demand for light and compact units, having smaller capacities than the larger rolling-drum type compressors. They are largely used for oil burners, aeration, displacement of liquids, gully-emptying, for the operation of vacuum brakes on commercial vehicles, and for the priming of centrifugal pumps.

Other exhibits include a group of hand or belt-driven compressors, and a Reavell compressed air anchor winch, which represents a range of air-operated deck auxiliaries built by the firm for tugs, coastal boats, yachts, &c.

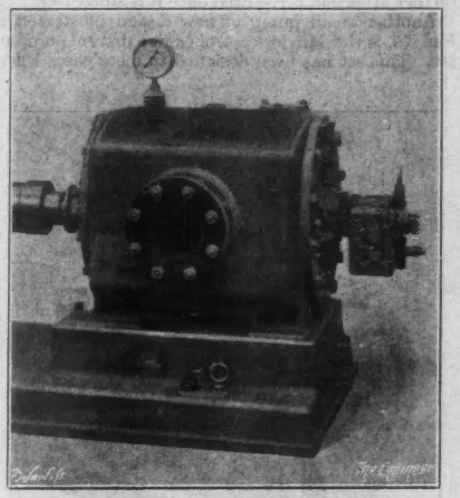

FIG. 74—ROLLING DRUM TYPE COMPRESSOR—REAVELL

Finally, there are exhibited on the stand three sectionalised Reavell-Ascania regulators, showing the operation of pressure regulators for low and high pressures, and for gas-mixing installations.

MIRRLEES, BICKERTON AND DAY, LTD., AND THE MIRRLEES WATSON COMPANY, LTD.

The principal exhibit on the stand of Mirrlees, Bickerton and Day, Ltd., of Hazel Grove, near Stockport, and the Mirrlees Watson Company, Ltd., of Glasgow, is the six-cylinder Mirrlees-Ricardo high-speed, four-stroke, airless injection oil engine, coupled to a standard Parsons 2 to 1 reducing and reversing gear, complete with thrust block propeller shaft and propeller, which is illustrated in Fig. II. of to-day's Supplement. The engine has a cylinder bore of 5⅝in. with a stroke of 6¼in., and a designed output of 120 B.H.P. at 1200 r.p.m. It is manufactured in two cylinder sizes of 20 and 50 B.H.P. per cylinder, with a range of powers of 60 to 400 B.H.P. As the engine has already been described in detail in our columns, no further comment on its design is necessary. A working model shows clearly the operation of the sleeve valve mechanism, and various parts of the engine are on view. Amongst the exhibits is a group of articles case-hardened by the Nitralloy process, the equipment for which has been installed at Hazel Grove, and the firm is prepared to undertake the hardening or the manufacture of component parts.

Photographs on the stand illustrate the Mirrlees direct-reversing, airless-injection, marine engines, which have been successfully employed in Thames tug work, and are now being embodied in an electric tug scheme.

Among the many pump exhibits of the Mirrlees Watson Company, Ltd., which include an 8in. single-stage, split-casing, centrifugal pump and a 4in. six-stage turbine boiler feed pump, is the vertical-spindle, self-priming pump, illustrated in Figs. XII. and XV. of to-day's Supplement. It has been developed for marine use, and the floor space occupied has been reduced to a minimum. The driving motor is mounted immediately above the pump, which is of split-casing design, with the suction and discharge branches at the back, thereby enabling the covers to be easily removed for inspection or overhaul. The air exhauster, which is of the rotary water-sealed type, is driven by a separate small motor, the motor and exhauster being built as a self-contained unit, which is bolted to a facing in the main pump frame. The opposite side of the frame carries a tank containing a supply of sealing water for the exhauster. The advantages claimed for this type of exhauster over the positive displacement rotary or reciprocating types are silence in operation, no lubrication difficulties, no rubbing surfaces in contact, and no danger of damage to the exhauster in the event of its drawing water. The suction of the exhauster is connected through a non-return valve to the highest point on the suction branch of the main pump and the exhauster discharge is led to the tank, sealing water circulating between the tank and exhauster all the time the exhauster is in operation. As the sealing water is kept separate from the liquid being handled by the main pump, the pump can be used for dirty or gritty liquid. The exhauster motor is controlled by the main pump starter and starts up along with the main pump, exhausting any air which may be present in the suction line. When the main pump gets water and pressure builds up in the volute, a pressure-operated switch comes into action and stops the exhauster motor. Should the main pump lose water, the switch automatically starts up the exhauster again, and it remains running until the main pump has been reprimed. The exhauster is thus only running when it is actually required, and wear and replacements are reduced to a minimum. The unit is silent in operation and, being entirely automatic in action, no further attention is required once it is started up.

Another small pump of new design illustrated in Fig. 75, is the Mirrlees petrol engine driven pumping set. This set has been designed to meet cases where no external source of power supply is available, and has a number of uses, such as for emptying gutters, supplying water for rural buildings, and general portable work for contractors. The model exhibited has a hopper-cooled $1\frac{3}{4}$ H.P. engine, and is mostly used for intermittent work, but for continuous running a tank-cooled model can be supplied. The pump is of the side suction type, the impeller being hydraulically balanced. At the coupling end, the shaft is carried on a ball bearing and a large gun-metal bush supports it close up to the impeller. Special attention has been paid to silencing, and two large thick-walled silencers are used, enabling the engine to be run indoors or in a confined space without objectionable noise. The capacity of the set is from 30 to 90 gallons per minute for heads up to 40ft.

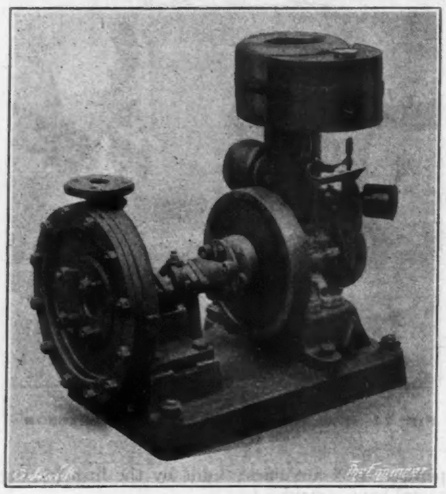

FIG. 75—PETROL ENGINE-DRIVEN PUMP—MIRRLEES

Another interesting pump exhibit is a compact motor-driven pump, in which the pump and motor are combined, the impeller being carried on the extended motor shaft. The impeller is of the single-entry type, with balancing shoulder at the back preventing any end thrust from coming on the motor bearings. The shaft is protected in the stuffing-box by a renewable sleeve. The discharge branch is on the top of the casing on the centre line, which makes alternative rotations unnecessary. Ease of installation is claimed for this new type of pump, which is designed for water supply and heating installations.

BROOM AND WADE, LTD.

The exhibit of Broom and Wade, Ltd., of High Wycombe, has been arranged to demonstrate under running conditions the firm's patented sleeve valve compressor, which is shown operating a wide range of "Broomwade" pneumatic tools. A view of the compressor, which was fully described in THE ENGINEER of September 11th, 1931, is reproduced in Fig. V. of to-day's Supplement. It has a piston displacement of 116 cubic feet, and is designed to deliver 100 cubic feet of free air per minute, when working at pressures up to 100 lb. per square inch. Another larger machine with mechanically operated valves is a 7in. by 8in. twin-cylinder unit, with a designed output of 130 cubic feet of free air per minute at pressures up to 120 lb. Several smaller machines of the reciprocating and rotary type are also on view. The main exhibit is, however, a display of drills and grinders actually in operation. In Fig. 76 we show the main component parts of a Broomwade multi-vane drill. The motor, which is of patented design, is of simple construction, the only wearing parts being the special fibre vanes which are easily and cheaply replaced, and give, we are informed, a long working life. The governor gear takes the form of steel balls housed in a conical race, which are moved out centrifugally and control the supply. The drills we inspected are silent in operation and free from vibration, and they cover the large drilling range of ¼in. up to 3in. diameter holes. Among the other exhibits worthy of special mention are a column-mounted yoke pattern riveter, and a neat form of pneumatically driven trench pump, which is designed to lift 10,000 gallons of water per hour against low heads and 3000 gallons against a 50ft. head, and is particularly suitable for dealing with waste water in contracting and quarry work.

J. AND H. McLAREN, LTD.

A wide range of airless injection oil engines of the high-speed type is shown on the stand of J. and H. McLaren, of Midland Engine Works, Leeds. A new model in a range for marine and industrial uses, embracing powers from 8 up to 320 B.H.P., is the McLaren lightweight engine, illustrated in Fig. XVI. of to-day's Supplement. It has a designed output of 20 to 25 B.H.P. at 1000 to 1250 r.p.m., with a bore of 95 mm. and a stroke of 125 mm. It embodies the principal features of the firm's patented design, including the special cylinder head and combustion chamber, illustrated in Fig. 78. The new design is light in weight, and very compact, and the reversing clutch is equipped with internal mechanism of the Parsons type. Arrangements can be made, however, for starting the engine either by hand, by an electric starter, or an air motor.

The larger 15 to $17\frac{1}{2}$ B.H.P. per cylinder units, which are constructed in combinations of two, three, four, six, and eight cylinders, with a bore of 135 mm. and a stroke of 200 mm., and for speeds of 800 to 1000 r.p.m., are also shown, the re-designed two-cylinder unit being of particular interest in this range. A still larger unit shown is the 40 B.H.P. per cylinder, 1000 r.p.m. engine, with a bore of 190 mm. and a stroke of 240 mm., which is supplied in four, six, and eight cylinder sizes. In Fig. 77 we illustrate the six-cylinder, 60 B.H.P. engine, which is equipped with a Parsons clutch, and McLaren inertia hand starter; a two-cylinder unit of the same series is also shown. The hand starter will be seen to the right of Fig. 77, and a section through a similar gear designed for pedal operation is given in Fig. 79. This drawing is self-explanatory. Essentially, the starter consists of an increasing gear, whereby a small fly-wheel is rotated at high speed, after which the inertia of the fly-wheel is utilised to start the engine through a worm and wheel. The first increasing mechanism comprises two chain wheels, the small wheel in the case of the pedal-operated gear being of the free wheel type. Mounted on the same shaft as the small chain wheel is a bevel wheel driving into a smaller wheel, which, again, through a large spur wheel, drives the fly-wheel of the inertia gear. This fly-wheel is mounted freely on the worm shaft, and runs on ball bearings. When the fly-wheel has been caused to revolve at about 3000 r.p.m., it is connected through the medium of a clutch to the shaft on which it is mounted, and formed with this shaft is a worm which gears with a worm wheel connected through a free wheel to the crank shaft of the engine.

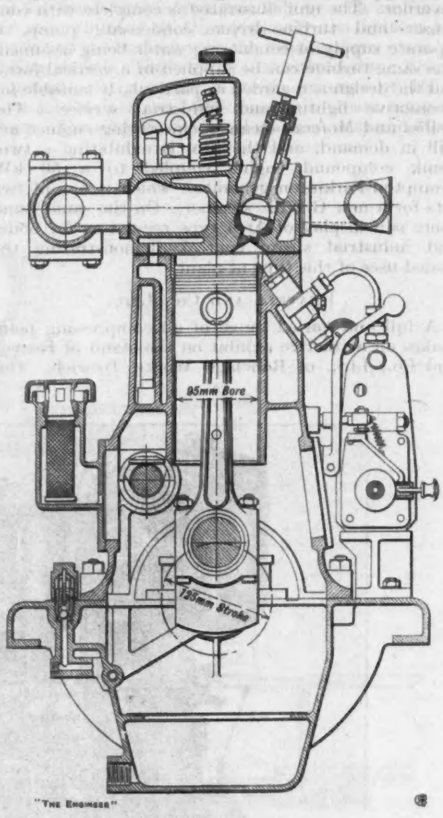

FIG. 78—SECTION THROUGH 20/25 B.H.P. OIL ENGINE—McLAREN

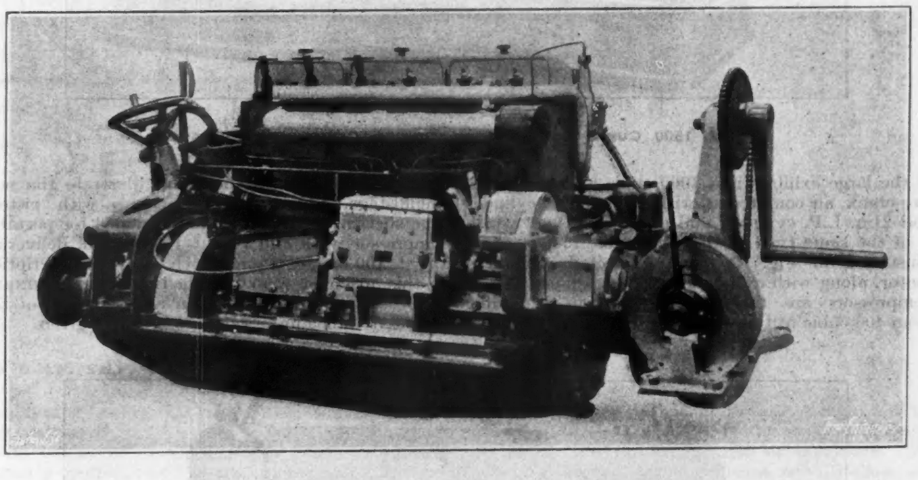

FIG. 77—SIX-CYLINDER 60 B.H.P. OIL ENGINE—McLAREN

The fly-wheel of the inertia gear thus drives the worm direct, consequently, the increasing gear used for winding up the fly-wheel does not transmit any power for starting up the engine. The clutch between the worm shaft and fly-wheel is of the plate type lined with Ferodo, and the operating mechanism for the clutch is so arranged that it is only necessary to pull the lever and slip in the clutch.

When electric glow plugs are used in connection with engines, the lever is so arranged that the current

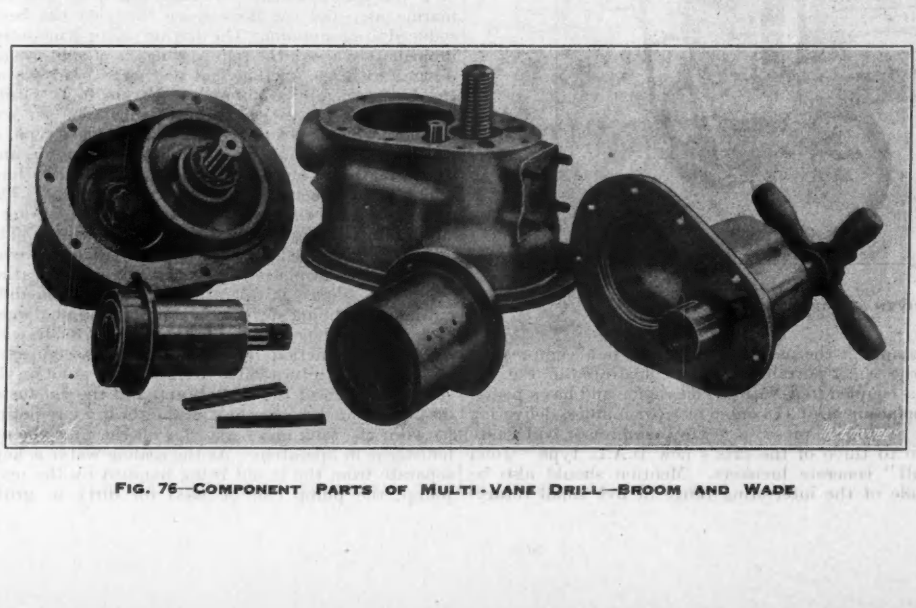

FIG. 76—COMPONENT PARTS OF MULTI-VANE DRILL—BROOM AND WADE

is cut off the plugs automatically immediately the clutch is let in to start the engine. In this case, of course, the electric glow plugs need only be switched on about ten seconds before the clutch is tripped.

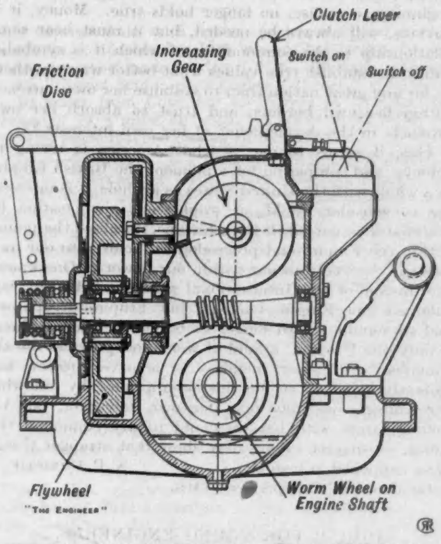

FIG. 79.—INERTIA STARTING GEAR—MCLAREN

RUSTON HORNSBY, LTD., AND RUSTON LISTER MARINE COMPANY, LTD.

The principal exhibit on the stand of Ruston and Hornsby, Ltd., of Lincoln, is a five-cylinder 150 B.H.P. auxiliary generator set running at 600 r.p.m. and coupled direct to a Sunderland Forge Company's 100-kW generator. This engine, which is illustrated in Fig. IV. in our Supplement, is one of eight similar units which are being supplied to Workman, Clark and Co., Ltd., for the motor ships "Ispingo" and "Inchanga," under construction at the company's Belfast yard for Andrew Weir and Co., Ltd. The principal features of this particular design of engine have already been dealt with in our pages. The fuel consumption obtained on the test bed works out to about 0·4 lb. of oil per B.H.P. hour at full load, 0·42 lb. at three-quarter load, and 0·45 lb. at half load. As several identical units have been in service for a considerable time, it is possible to state that, according to the makers' and users' repair and maintenance returns, the cost of upkeep is very small. A smaller Ruston-Hornsby engine also shown on the stand is the 96 to 104 B.H.P. six-cylinder unit, designed to develop the powers named at speeds of 900 to 1000 r.p.m. Both the engines run on the airless injection principle.

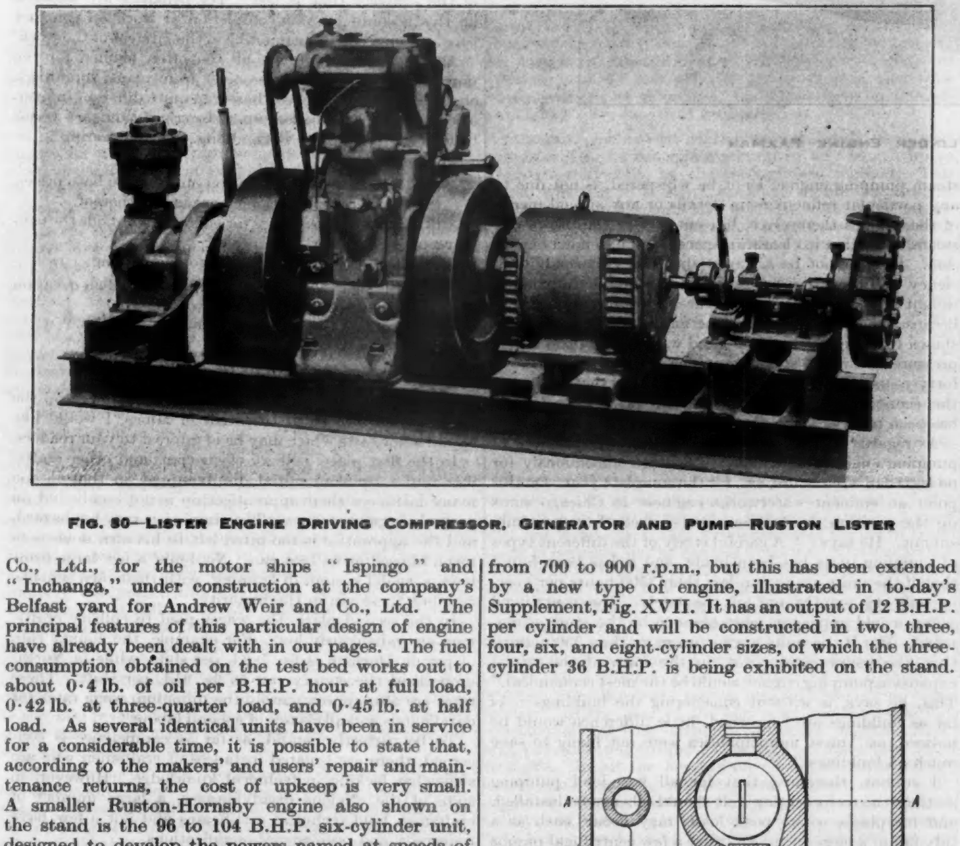

FIG. 80—LISTER ENGINE DRIVING COMPRESSOR, GENERATOR AND PUMP—RUSTON LISTER

The exhibits of the Ruston Lister Marine Company, Ltd., of Imperial House, Kingsway, London, W.C.2, include a four-cylinder 35 B.H.P. unit and a two-cylinder 17½ B.H.P. unit, both of which run at 1000 r.p.m. and incorporate in the cylinder design the Lister patented combustion chamber. A smaller 14 B.H.P. engine complete with reverse gear is on view, and also an auxiliary set shown in Fig. 80, which comprises a 7 B.H.P. single-cylinder Lister engine coupled on the one side to a Hamworthy 10 cubic feet 30 lb. per square inch air compressor and on the other to a 1·5-kW 100-volt Lister generator and a service pump. The whole line of machines is designed to run at the standard engine speed of 1000 r.p.m.

GLENIFFER ENGINES, LTD.

Since Gleniffer high-speed oil engines were first shown at the Shipping, Engineering and Machinery Exhibition of 1929 considerable numbers have been installed in all kinds of marine craft, both for main propelling and auxiliary work. The engines shown this year incorporate improvements in details of design which have been made as a result of the experience gained, but the three outstanding features of the Gleniffer engine remain—the air motor method of starting, the automatic lubrication system, and finally its high flexibility, which is demonstrated on the stand by the running of a six-cylinder 120 B.H.P. engine. The firm is also exhibiting one of its standard reverse gears. The normal range of Gleniffer engines is from 45 to 160 B.H.P. at speeds varying from 700 to 900 r.p.m., but this has been extended by a new type of engine, illustrated in to-day's Supplement, Fig. XVII. It has an output of 12 B.H.P. per cylinder and will be constructed in two, three, four, six, and eight-cylinder sizes, of which the three-cylinder 36 B.H.P. is being exhibited on the stand.

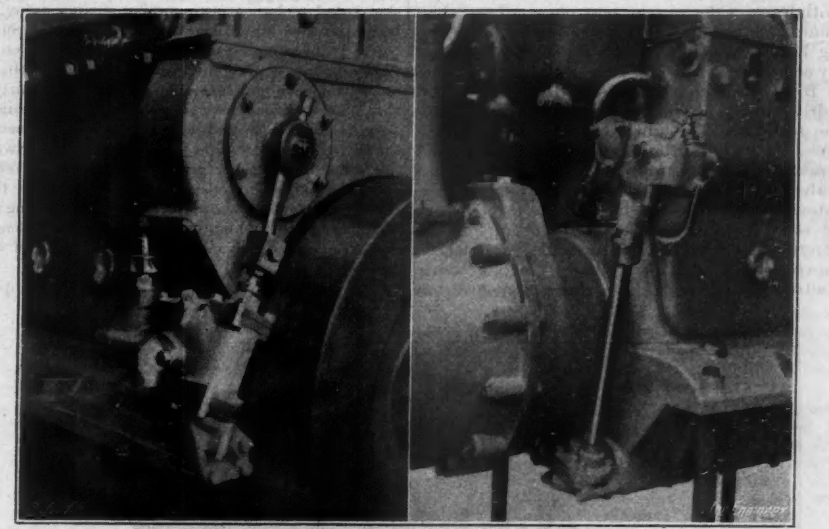

FIG. 81—ARRANGEMENT OF CIRCULATING WATER AND LUBRICATING OIL PUMP DRIVES—GLENIFFER

The design, while following closely that of the earlier engine, incorporates new features. We may refer to the neat V form of air starting motor, shown to the left of our illustration, near to the fly-wheel. Other interesting features, shown in Fig. 81, are the circulating plunger type water pump driven from an excentric on the end of the cam shaft, and the drive to the submerged oil pump which supplies the main bearings and gudgeon pins. A relief valve fitted to the system also furnishes an oil feed to the cam boxes and through the hollow cam shaft to the timing chain. A neat form of governor control with a hand speed control lever is fitted. A pleasing feature is the completely jacketted exhaust manifold and a water injection silencer, which is fitted to the after end of the engine.

THE ELECTRO-MECHANICAL BRAKE COMPANY, LTD.

We illustrate in to-day's Supplement, Fig. XVIII., the three-cylinder, 40 B.H.P. marine oil engine of the Wiseman type fitted with reduction and reversing gear, and exhibited as a running unit by the Electro-Mechanical Brake Company, Ltd., of Moor-street, West Bromwich. It has a bore of 4in., a stroke of 6in., and a full load running speed of 1500 r.p.m. A feature of the engine is the patented design of cylinder head —see Fig. 82—and combustion chamber, which has been designed to give the air charge a high rotational velocity, both on the compression and firing strokes, thereby ensuring not only complete combustion, but also making the engine exceptionally easy to start up by hand from cold. The easy starting of the engine and its smooth running is demonstrated on the stand. The air charge is drawn from the cylinder covers, which, it is claimed, obviates the disagreeable odour produced by any stray oil on the hot cylinder heads. Forced feed lubrication to all parts of the engine is provided, and a governor, adjustable to any speed while running, is incorporated in the design, while an independent control allows the engine to be instantly stopped without affecting the normal governor control. A low-pressure fuel pump is fitted to serve the injection pump, which is of the Bosch pattern, thereby allowing the fuel tanks to be fitted in any convenient position. The engine is constructed in one, two, and three-cylinder units, with a speed range of 200 to 1500 r.p.m., and normal rating of 12 to 13 B.H.P. per cylinder.

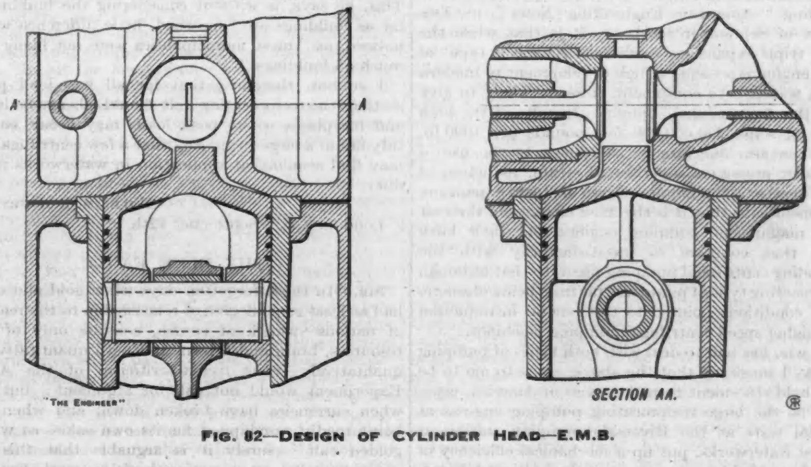

FIG. 82—DESIGN OF CYLINDER HEAD—E.M.B.

DAVEY PAXMAN AND CO. (COLCHESTER), LTD.

The largest engine on the stand of Davey Paxman and Co. (Colchester), Ltd., of Colchester, and Aldwych House, London, W.C.2, is the 300 B.H.P., six-cylinder, airless injection engine coupled to a 200 kW generator running at a speed of 600 r.p.m., which we illustrate in Fig. 83, while a new engine is the four-cylinder, 100 B.H.P. direct reversing engine which runs at 750 r.p.m. A view of this unit in course of completion in the makers' works is given in to-day's Supplement, Fig. XIX. In general construction, both units are similar, a monobloc type cylinder casing being used with through-going bolts to the bed-plate, which take the combustion stresses. Large inspection doors form a feature of the design, and they are so dimensioned that after freeing the big end, the piston and connecting-rod can be lowered into the crank pit and withdrawn sideways in one piece. Less than two minutes is required for this operation after the bearing has been undone and the piston can be as quickly and easily replaced. There are two cam shafts driven from the crank shaft by a Renold enclosed chain drive, and these, in turn, drive the fuel pumps and the governor. The lubricating system includes a pressure supply to the running parts with a separate low-pressure pump for supplying oil to the cam shaft and valve gear from the cam shaft troughs. The generator unit is controlled by a single lever, while, in the case of the marine type reversing engine, manœuvring is carried out by a single hand wheel, the movement of which in either direction starts and controls the speed of the engine under governor control as may be required. The gear is simple in design, and is claimed to be accident-proof, a feature being that there is no moving of the cam shafts with the cams, rockers, &c. The arrangement adopted is particularly suited for control from the bridge if this is desired. The marine engine, as our illustration shows, is complete with its service pumps and starting air compressor, or dynamo, and a thrust bearing is incorporated in the design. The 300 B.H.P. engine has a bore of 9in. and a stroke of 12in., while the 100 B.H.P. reversing engine has a cylinder bore of 6½in. and a stroke of 10in. The company manufactures a range of high-duty engines from 50 to 1500 B.H.P. for industrial and marine use, and for locomotive work.

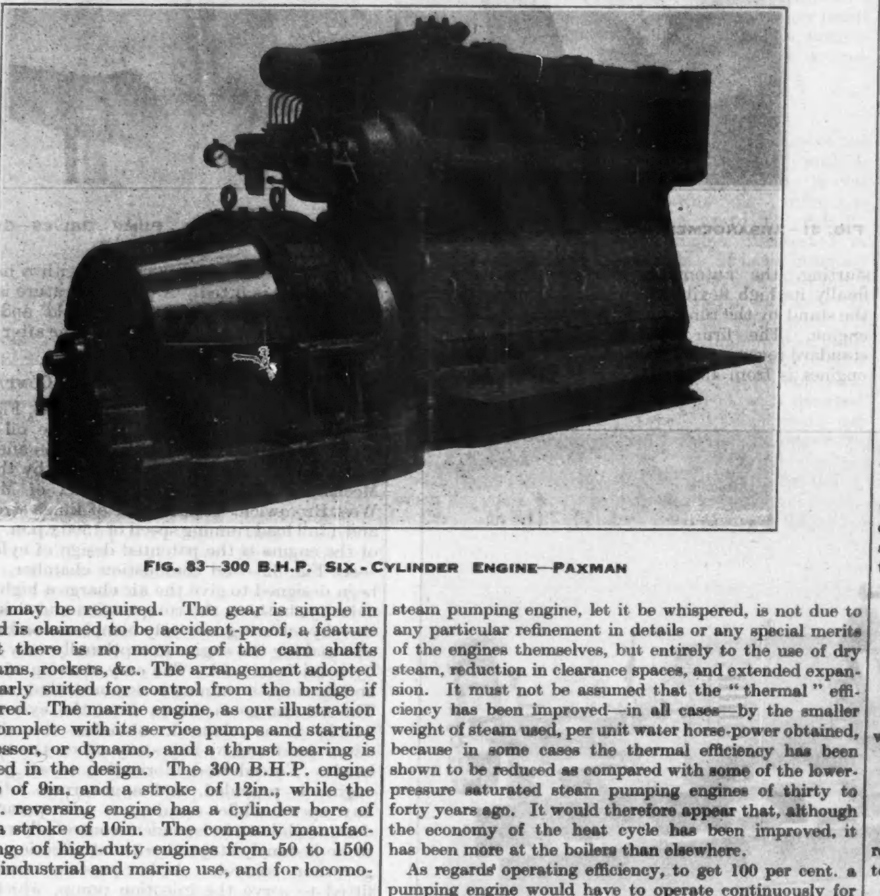

FIG. 83—300 B.H.P. SIX-CYLINDER ENGINE—PAXMAN

WATERWORKS PUMPING MACHINERY.

SIR,—A rather significant statement appeared under the heading "American Engineering News" in THE ENGINEER of September 1st last. It is that while the inverted triple-expansion crank-and-fly-wheel type of pumping engine represents a high development in modern American waterworks equipment, it seems likely to give place to the "centrifugal" pump. In spite of the high efficiency of some 200,000,000 foot-pounds per 1000 lb. of "dry" steam, due largely, of course, to the use of higher boiler pressures, superheated steam, reduction of clearance spaces, and a greater degree of steam expansion, the statement says that it is the fixed charges on the cost of these magnificent pumping engines and their lofty buildings that compare so unsatisfactorily with the corresponding centrifugal pumping plant, so that although the reciprocating type of pump was far from being obsolete, economic conditions pointed to the general introduction of these higher speed centrifugal pumping machines.

As one who has had to deal with both types of pumping machinery, I must say that the above seems to me to be a pretty bold statement to make, even in America, especially so as the large reciprocating pumping engines at the official tests at the Riverside pumping station at Milwaukee waterworks, put up a mechanical efficiency of no less than 98·14 per cent., namely indicated horse-power in the steam cylinders of (by cards) 1121·88, and "water horse-power" of 1101·01. Surely such a splendid performance can defy the best endeavours of any type of centrifugal pumping plant. It is true that the steam turbine can be made very efficient when using very high temperature steam, and that in very large powers—much above that essential or desired for waterworks pumping—it is also comparatively more efficient than a reciprocating unit may be, but, even then, it surely cannot be assumed that the reliability and all round variable head pumping efficiency can be so good as that attained by the slow-speed "ram pump" for the commercial purposes of moving water. As an example of the long life which these slow-speed reciprocating pumping engines enjoy, it may be stated that Milwaukee City purchased in 1891 for its North Point pumping station an 18,000,000-gallon vertical triple-expansion pumping engine, which held the world's record for economy for some time. After thirty years' continuous service it was thoroughly overhauled at a very nominal cost and was then placed in service for another thirty-year run. During the forty-two years' operation it has never given the waterworks officials or their staff the least anxiety, and I do not believe there has ever been a breakdown, and this type of pumping machine has maintained its high pumping duty over a long period of years, and with a most remarkable low cost of maintenance.

The improved economy in the modern reciprocating steam pumping engine, let it be whispered, is not due to any particular refinement in details or any special merits of the engines themselves, but entirely to the use of dry steam, reduction in clearance spaces, and extended expansion. It must not be assumed that the "thermal" efficiency has been improved—in all cases—by the smaller weight of steam used, per unit water horse-power obtained, because in some cases the thermal efficiency has been shown to be reduced as compared with some of the lower-pressure saturated steam pumping engines of thirty to forty years ago. It would therefore appear that, although the economy of the heat cycle has been improved, it has been more at the boilers than elsewhere.

As regards operating efficiency, to get 100 per cent. a pumping engine would have to operate continuously for no less than 8760 hours, *i.e.*, for the complete year. On this point an eminent waterworks engineer in Chicago sums up the position in America pretty well, I respectfully submit. He says: "A careful study of the different types of pumping units has been made, and it has been found that if the units are to run less than 3500 hours per year, or only 4¾ months out of the twelve, the centrifugal pump would appear in most cases to be the more economical. But if the units are to run more than 3500 hours, then the reciprocating unit, in the form of the triple-expansion pumping engine, would be the most economical." This, he says, is without considering the buildings. As far as buildings are concerned, little difference would be noticed, as "most municipalities were not likely to save much on buildings."

I submit, therefore, that for all base-load pumping stations the reciprocating unit should always be installed, and for places where peak loads may occur, such as a tidy fire in a large town, &c., that a few centrifugal pumps may find economical application in waterworks pumping duty.

WILLIAM P. DURTNALL.

London, S.E.5, September 12th.

THE BLUE EAGLE.

SIR,—In those forgotten days when gold and currency had at least some degree of relationship to the real wealth of nations—which, of course, consists only of natural resources, brain and brawn, and both quantitatively and qualitatively—your recent criticism of the American Experiment would not call for argument; but to-day, when currencies have broken down, and when gold is being madly worshipped for its own sake—as was "the golden calf"—surely it is arguable that this gallant experiment to get a nation back to work has a very logical basis, and one that the British Empire may well find it necessary to follow?

The psycho-analyst will tell us that the eagerness with which a young child will extend its hand for a proffered coin, the smile on our bank manager's face if we pay in a big cheque, and the reluctance of the Middle West farmer to forego war debts, are all symptomatic of an atavistic instinct which we, I suggest, are only beginning to realise, no longer holds true. Money, it is obvious, will always be needed, but it must bear some relationship to the commodities of which it is symbolic, and to re-establish true values what better way can there be for any great nation than to stabilise her own currency within her own borders, and trust to absorb her own products in the development of her own interests?

This, it seems to me, is what America is trying to achieve, and comparing for a moment the British Empire as a whole with the United States as a whole, it is interesting to consider would, or would not, our position be bettered if we cut adrift from Europe, stabilised the pound within the Empire and proceeded to "cultivate our own garden" by every means within our power? One knows the answer of the International group in advance, but they are not Empire builders, but Empire dissipators, and we cannot afford longer to be led by them. There is only one Utopia; a land of work and progress for all. America, with fewer facilities to achieve success, has gallantly begun to act on this assumption; by following her example we may find our own salvation, but by joining forces with her we could jointly command the world. I suggest events may show that stranger things have happened in history! S. P. CHRISTIE.

London, S.W.7, September 14th.

DIVING FOR YOUNG ENGINEERS.

SIR,—The good advice given on the above subject in your last issue, is of much interest to those who are, or have been, engaged on this class of work. A matter of importance, however, seems to me to have been overlooked. It is, that no amount of training on under-water work is of much assistance to the worker or inspector of work unless accompanied by the natural gift that all must possess to be efficient. The gift of touch is a rare one. The diver seldom sees his work; he feels it.

A point I would like to see pressed home and one that would help the profession, "the black sheep," the contractor, and those responsible for difficult and oftentimes dangerous work, is—That no contractor should be held responsible for conditions outside his control, viz., bad sea conditions, whereby as much as 75 per cent. of the contract time is lost. Yet penalties are imposed on this account for non-completion of work on contract time. Such a penalty cannot be in the interest of the work.

Again, the contractor is all too often blamed for the unreliable information he receives from plans, soundings, etc., his prices having been based on quite different information. Yet he is called upon by rigid contract terms to foot the bill. That is gambling, not engineering.

The moral is:—

(1) Give Reliable information on which to base prices.

(2) Add a compensation clause in lieu thereof.

(3) Impose no penalties for conditions outside the contractor's control.

(4) Stop gambling and stick to engineering.

There will then be no black sheep to charge on occasion with bad constructional under-water work.

London, S.W.14, September 19th. W. T. G.

COLLIERY ELECTRICIANS.

SIR,—With reference to your editorial comment on the report of the Electrical Inspector of Mines, I would like to add a few facts which may be of interest to your readers.

In the first place, colliery electricians and other craftsmen suffer from an initial disadvantage, in that in too many instances their apprenticeship is not conducted on properly organised lines. The training is very haphazard, and the apprentice is too often left to his own devices to teach himself as he best can. No doubt a few large firms have a model system of training, with their own schools, &c., but these are in the minority.

In the second place, the wages paid to colliery craftsmen are ridiculously low. For example, the county rate of pay in Durham is 6s. 7·2d. per shift, while in Northumberland the county rate is 6s. 9½d. per shift. These rates are also approximately the minimum wage rates for datal hands and all classes of general labour!

To be perfectly candid, as far as competence is concerned, there are isolated instances of craftsmen who are somewhat lacking in technical knowledge. However, in spite of the obvious disadvantages, a large number of craftsmen hold technical certificates and not a few have university and professional qualifications.

Whilst on the subject of certifications, I think it should be made compulsory that colliery engineers, assistant engineers, and others holding responsible positions should hold a recognised qualification, such as membership of one of the major institutions.

September 16th. A.M.I. MECH. E.

MACCLESFIELD WATER SUPPLY.—At 10 a.m., Saturday, September 9th, Mather and Platt, Ltd., Park Works, Manchester 10, received an order from the Macclesfield Corporation for an emergency pumping plant, and within ten working hours had installed a 2in./3in. electrically driven "Medivane" pump of 3400 gallons per hour at 100ft. head capacity, driven by a 7½ H.P. squirrel-cage induction motor, complete with necessary control gear valves, and suction and delivery piping. The water supply has been obtained by erecting a dam across the Pyegreave stream at Langley, which is fed by four springs on the hillside, and in the event of rain and an increase in the water supply from the springs the pump is capable of delivering a larger output. The set was despatched from the works at twelve noon on Monday, September 11th, and erected on site the same afternoon. As a result of this quick work and organisation Macclesfield water supply is now increased by approximately 70,000 gallons per day.

Railway and Road Matters.

An express train with seven coaches achieved during the evening of September 19th what is believed to be the fastest run ever made on the L.M.S. Railway. Hauled by the "Royal Scot" class engine "Comet," it covered the 94 miles from Coventry to Euston in 75 min., an average of 74·8 miles an hour. A speed of 92 miles an hour was twice reached during the journey.

The works of the Stockton and Darlington Railway—opened on September 27th, 1825—were at Shildon in South Durham, and there Timothy Hackworth had his, headquarters. The Railway Institute at Shildon was built soon afterwards, and the centenary of its establishment is about to be celebrated under the patronage and with the support of the chairman, directors, and chief officers of the London and North-Eastern Railway.

The increases, week by week, in the passenger traffic returns, must not, as we have before advised, be regarded as signs of improved trade; they are due mainly to the remarkably fine weather and the introduction of "summer" return tickets. A better sign is to be found in the three larger groups reporting increases, for the thirty-sixth week, in both merchandise and coal traffic. The Southern now reports an increase for the year to date, and the losses on the other companies have been much reduced.

The L.M.S. Railway Company has placed with a Middlesbrough firm a contract for the reconstruction of a bridge carrying the Acton Branch over Acton-lane, Willesden, N.W. The allocation of this contract represents a further stage of the scheme which the L.M.S. have in hand for strengthening the bridges on the Cricklewood to Acton branch in order to carry larger locomotives. Two bridges, including one over the Edgware-road at Cricklewood, have already been rebuilt, while the reconstruction of another, over Neasden-lane, is now in progress.

To the surprise of the railway people present and others interested, the coroner's inquest, arising out of the Little Salkeld collision of July 10th, was, on September 12th, further adjourned until October 16th, because the civil authorities had not completed their inquiries. In this case an express passenger train ran past the signals and collided with a goods train, the driver of which received fatal injuries. As there were, we believe, extenuating circumstances in favour of the driver of the express, the further postponement of the opportunity to make all the facts known is to be regretted.

An important improvement scheme is being carried out by the L.M.S. Railway at the motive power depôt at Nuneaton, where a large number of engines are stationed for working passenger and freight services in the Trent Valley area. New equipment which is being installed includes a mechanical coaling plant to replace the present coaling stage, and a mechanical ash-lifting plant, which will deliver locomotive ashes direct from the ash pit into wagons for disposal. Improvements are also being made to the general lay-out of the shed yard, which will reduce the amount of shunting to be done by engines.

Three stations on the Underground have been greatly improved. One is the combination of the Central London British Museum Station with the Holborn of the Piccadilly Tube; the next is the new Green Park Station near the Ritz Hotel, which will displace Dover-street Station; the third is the new subway and escalators that will join the Monument Station on the Inner Circle with the Bank Station of the Central London. The second and third of these were opened on September 18th. The improvements at Knightsbridge and Chancery-lane are hoped to be finished by the end of the year.

The misfortunes of the Great Orme Tramway, which followed the fatal accident on August 23rd of last year, have more than once been referred to in our pages. That attention on our part has been due to the fact that after the line had been inspected and passed by the Board of Trade an automatic emergency brake was withdrawn, and therefore was not available when the drawbar broke. After the accident the line was closed, and the Ministry of Transport will not permit it to be reopened until its requirements have been complied with. Meanwhile, the property has passed into the hands of a receiver, as a consequence of failure to pay damages that had been awarded for personal injury. We mention the subject again because at a meeting of the creditors it was stated that efforts were being made to comply with the requirements of the Ministry; whilst not completely successful, they had given indications of being on the right lines. It was also revealed that the tramway company has taken action against the maker of the drawbar, but the case has not been brought to trial.

The passing of the Metropolitan Railway prompts the observation that that company was, in many directions, a pioneer in railway signalling. When, for instance, its line between Praed-street and Aldgate was equipped with automatic signals, the electro-pneumatic system of operation, used on the Metropolitan District and the tube railways, was not employed, but the all-electric method, as since installed on all other lines, except those just named, was used. In 1911 locking bars at facing points were dispensed with and the points held instead by a length of track circuit—a practice that is now universal on all railways. In the same year automatic semaphore signals, with arms moving in the upper quadrant, were fixed between Finchley-road and Neasden, and in 1912 a great economy in men was effected by providing fog-lights in place of fog-signalmen. In 1926 the first long-distance point mechanism was installed on the east side of Euston-square Station, wherein the points were worked from King's Cross box, 660 yards away. The locking frame at Wembley Park, wherein the interlocking is actuated electrically, was the first such frame outside the Southern Railway—where it was originally introduced—and from the same box is actuated the first instance of centralised traffic control outside North America. That actuates the points and signals at Stanmore, 4½ miles away. Both these works were opened in 1932, and since then the two mechanical locking frames at Farringdon-street and Aldersgate respectively, have been electrically interlocked.

Notes and Memoranda.

The Pelton wheels in the Niederenbach hydro-electric station, in Switzerland, work under a net head of 3280ft. The total static head is 3560ft. There are two units, each of which is rated at 11,450 H.P., and runs at 750 r.p.m. They drive 11,000 kVA, 8800-volt generators. Each turbine has only one bearing, and is directly coupled to a two-bearing generator.

According to a paper recently prepared for the Canadian Institute of Mining and Metallurgy by Ralph H. Cleland, of the Ontario Department of Mines, rock temperatures rise by 1 deg. Fah. for each 220ft. in depth in the Porcupine gold mines, and for each 160ft. at Kirkland Lake and Sudbury. Canadian mines can, he estimates, be carried to a depth of 6500ft. or more without difficulty.

Apparently, according to the *Rangoon Times*, one of the chief causes of derailments on Indian railways is the malicious removal of fish-plates. To stop this practice Mr. J. A. Guest has invented the Guest-Avatt fish bolt. From the brief description given, it appears that the bolt, after being passed through the fish-plates and rail is bent down and passed through a hole in the sleeper. The nut is screwed on beneath, where it is not easily accessible.

An electrolytic method for the purification of mercury was recently described by Professor E. Newbery and Mr. S. M. Naude, of Cape Town University, to a meeting of the American Electro-chemical Society. A mercurous perchlorate electrolyte is used with a cathode of pure mercury, an E.M.F. of 0·5 volt, and a current density of about 1 amp./dm.^{2} The chief difficulty encountered lies in the formation of crusts of solid salt over the exposed surface of the anode. Spectroscopic examination of the product indicates that a high standard of purity is obtained by this process.

The fact that upon exposure to light a change in the electrical resistance develops in certain thallium compounds has, according to an article in the *Chemical Trade Journal* by Dr. J. C. Munch, led to a practical application. The "thalofide cell" contains thallium oxysulphide as the effective agent. In preparing the thalofide cell, thallium oxysulphide is fused on a quartz plate, and mounted in an evacuated bulb to prevent oxidation. The most sensitive bridges of this material show a change of 50 per cent. in electrical resistance for an illumination less than 1 metre-candle. The dark resistance varies from 5 to 500 megohms, and these bridges have a large temperature coefficient. Their response is essentially linear over the entire range; 0·06ft. candles of light will be detected. These thalofide cells are very rapid, the current increase normally occurring in less than one one-hundredth of a second, and showing a maximum action at a wave-length of 1·05 μ.

Straight cylindrical work without heads can, says the *Iron Age*, be centreless ground in any length up to approximately 24ft. by the through-feed method. This work, whether it is short or long, should be straight before passing through the machine. It is necessary that before centreless grinding long bars be machine straightened, or at least straightened to the same degree as obtained by machine straightening. If the long bars are not straight before grinding, they will whip both on the entering and leaving sides of the wheels and the work will make contact with the corners of the grinding wheel, thus causing spiral marks to appear on the ground surface of the bar. Long bars up to 4in. in diameter by 24ft. long have been successfully ground by the centreless method. When grinding bars of such length, it is necessary, of course, to provide auxiliary supports at both front and rear of the machine, in order properly to support and align the bar before it enters and after it leaves the grinding cut.

Nitrogen, when uniformly alloyed in the chromium and the nickel-chromium steels, and in amounts of the order of 0·20 to 0·30 per cent., has been found to impart such beneficial effects that a broadening of the use of these steels is regarded as the natural outcome. The researches bearing on the subject in the Union Carbide Laboratories, Long Island City, New York, are described in the *Iron Age* by R. Franks. Castings and also the wrought steels, including those of the stainless class, respond to the addition of the nitrogen. In the case of the high-chromium alloy castings, a product is obtained that withstands abuse without cracking, suggesting its application in pump impeller parts having great differences in cross section. In the case of the chromium-nickel steels, the introduction of the nitrogen improves machinability and provides non-magnetic castings of relatively high strength. In all the low-carbon classes of these alloys, considerable ductility and toughness is added and a non-magnetic wrought material of high yield point, machinability, and resistance to staining is obtained. The nitrogen is added in the form of high-nitrogen ferrochromium, as explained in the article.

A new process patented for the preservative treatment of timber to be used for telegraph poles or railway sleepers consists in injecting an impregnating medium into the sap stream of the living tree. The usual impregnating media are carried imperfectly, if at all, by the sap, but, according to Max Knopff, writing in *Telegraphen- und Fernsprech-Technik*, arsenious acid, arsenic acid, or their easily soluble salts, can readily be conveyed from the base of the trunk to the ends of the branches by this means. Bore-holes in the trunk are filled with the treating material in the form of a solid paste, or concentrated solution. The openings being closed by plugs of wood, plaster, or clay, the arsenious compounds are disseminated by the sap flow, and the tree is soon killed and thoroughly impregnated; it can be left to season before being felled. The cost of treatment is further reduced by the fact that the arsenious compounds are capable of carrying with them other and cheaper impregnating materials which cannot be carried by the sap alone. Satisfactory results are said to have been obtained with a mixture of seventy-five parts arsenic acid with twenty-five parts sodium fluoride, and with a mixture of sodium arsenite and benzoate in equal parts.

Miscellanea.

A factory for the production of titanium pigments is being put up at Billingham-on-Tees.

It is reported that a very extensive graphite deposit has been discovered in the neighbourhood of Pelion, Greece.

Distilleries for the manufacture of industrial alcohol will shortly be established in the Irish Free State under the control of the Government.

It is proposed to construct a hydro-electric power plant, with a capacity of 750,000 horse-power, at Orsova, where the Danube crosses the Rumania-Yugoslovak border.

A new hydro-electric plant is to be constructed on the Nagara River in Japan. The output is to be about 40,000 kW and the costs are estimated at £460,000 inclusive of transmission lines.

Mining work is proceeding at full speed in the territory of the Balachtinsky gold-bearing region of Western Siberia. Mines will soon be ready for exploitation. A town for the workmen consisting of 500 flats and an electrostation are under construction.

Draft rules for the port of Vizagapatam have been gazetted. It is announced that the new Vizagapatam harbour will be opened to ships of 27ft. draught in October or November, and that it will be formally opened, perhaps, by the Viceroy of India, in January.

One of the biggest blasts in the history of quarrying, according to an account in the *Iron and Coal Trades Review*, took place on Wednesday at Raynes Quarry, Llysfaen, Colwyn Bay, when between 60,000 and 70,000 tons of limestone were dislodged. It had taken the borers weeks to get ready for the blast. The quarries are now owned by Imperial Chemical Industries, Ltd.

Following a series of trials between Toulouse and Saité Foy de Peyrolieres, the Compagnié des Chemins de Fer du Sud-Ouest Français has decided to adapt its system to accumulator traction, and an order has consequently been placed for a number of electric locomotives weighing 34 tons each, capable of attaining a speed of 37½ m.p.h. Each engine will be fitted with four motors developing 50 H.P. each at 800 r.p.m., and with power at 125 V supplied by an 800-Ah, 135-cell battery.

The Christmas Island Phosphate Company has for some time past maintained a small wireless station, which is being extended and modernised by the provision of two Marconi stations for direct communication with Singapore and with distant ships. The link with Singapore is by short wave, utilising a transmitter covering the waveband of 20 m. to 100 m., with a power to the aerial of 250 W when operating continuous wave telegraphy, for which it is particularly designed. For working with ships on medium wave lengths, a special 200-W transmitter has been supplied. Christmas Island is 800 miles south of Singapore in the Indian Ocean.

The Dominion Bureau of Statistics at Ottawa reports that during the first six months of this year, the output of primary steel totalled 130,464 tons, as compared with 180,488 tons for the corresponding half of 1932, and with 461,877 tons for the first half of 1931. Production of ferro-alloys during the six months totalled 6078 tons, as compared with 8759 tons during the corresponding period a year ago. On June 26th, a 350-ton blast-furnace went into operation at Port Colborne, Ontario, and a 55-ton furnace was blown in at Sydney, Nova Scotia, on June 28th. Pig iron production in June totalled 857 long tons, being the first pig iron made in Canada this year since February 14th.

It is probable, says Mr. Ludlow, of the American Institute of Architects, that skyscrapers will not be built again for many a long day, perhaps never; one reason being that the exodus of population from the big cities of America has already begun, and the congestion in cities, of which the skyscraper is a product, is slowly yielding. This is an interesting theory, and we hope that it has some foundation in fact. Under present conditions in large cities, cost of living is increasing due to high rentals, and far too much time is wasted daily in transportation. Serious traffic problems are caused by the people employed in these high buildings, all entering or leaving the buildings about the same time. Abandonment of the skyscraper would eliminate many problems now facing town-planning engineers.

Speaking at the Humber-Hillman Works at Coventry, on Tuesday last, Dr. E. L. Burgin, Parliamentary Secretary to the Board of Trade, said that the British motor industry began its post-war expansion in 1923, and in that year manufacturers made about 71,000 private cars and 23,000 commercial cars. In 1932 the figures had increased to 171,000 private cars and 61,000 commercial cars. In 1925, 41,000 private cars and about 6000 commercial vehicles were imported. In 1932 only 2762 private cars and 310 commercial vehicles were imported. Those figures gave ground for confidence in the development of the industry. In 1924, 15,000 vehicles were exported. In 1932 that figure had become 40,000, and for the first eight months of this year it was 33,000. If manufacture continued at the same rate, the total for the year would be nearer 50,000 than 40,000 vehicles.

Although the majority of the furnaces used for the production of calcium carbide, cyanamide, and iron alloys in France are of the single-phase type, furnaces employing three-phase power are, says the *Electrical Review*, gradually coming into use, two large ones of this variety having lately been constructed in the Pyrénées. The first, which has a capacity of 11,000 kW, has been installed at the works at Marignac of the Société des Produits Azotés to replace four 3500-kW furnaces used for the production of carbide. The furnace, which is of the Soderberg three continuous electrode type, has been developed in conjunction with the Société des Electrodes de la Savoie. The second furnace, which has been installed at the Lannemezan works of the Société des Produits Azotés, has a capacity of 12,000 kW, and is also used for carbide production. The electrodes in this case are, however, not continuous, but are similar to those used in Germany by the Stickstoff Company.

SCIENCE AND PROGRESS.

To an evening discourse at the recent meeting of the British Association Sir Josiah Stamp gave the title " Must Science Ruin Economic Progress." The address, the substance of which is printed on page 294 of this issue, was well received, but it is of the kind that calls for greater application than even the most attentive and acute minded can give in the atmosphere of a lecture hall. For it is a closely reasoned philosophical inquiry into the relationship which does exist, and which might exist, between technological developments and the progress of mankind towards greater contentment. But besides being coldly logical and philosophical it is inconclusive. Sir Josiah expresses neither faith in man's ability to make the best of all that science and technology offer him, nor assurance that science is inimical to economical progress. He aligns himself neither with that party which abhors mechanisation nor with that which supports it. His position is one of calm detachment. He seems to say: " I give you the facts; it is for you to sort them out and draw your own deductions." No doubt he would add, under his breath, " Each one of you will, of course, select the facts that suit him and draw from them the conclusions he wishes to draw." That is a persistent human weakness, from which not even scientists always escape, and from which economists never do. The old saying, " Given a twelfth immersion microscope and a lively imagination, and you can see whatever you desire to see," is as true of economics as of other sciences. It may be that in a less sophisticated past economic issues were simpler than they are to-day, and that no more than macroscopical examination was required to see whither they led. But now they have to be examined with a microscope, and in the vast complexity of elements which are presented it is always possible to pick out those that suit one's own hypothesis.

For this reason Sir Josiah Stamp's address is salutary. It deals only in a broad way with the numerous factors involved in a problem which is disturbing the whole world, and concentrates attention on fundamental economic principles. Whether other economists will accept or reject those principles remains to be seen. Some of them appear to be startling enough to ensure immediate repudiation. When, for example, Sir Josiah asserts that " the *basic* economic reason for social unemployment relief is not the humanitarian argument of social obligation against distress, *or* the argument against revolution, but the plain argument that the gainers by innovation should bear the losses of innovation," we suspect that those who master the full meaning of the assertion will scarcely be content to accept every implication of it. If, to take but a single obvious example, a manufacturer introduces a new labour-saving appliance—an innovation—are we to understand that he must therefore make himself responsible for the labour the new appliance displaces? We ask the question in a spirit of inquiry, not of opposition, and in asking it we recall that under the Swope plan in the United States each industry was to make itself responsible for its own unemployed. But it would be unfair to pick out from the address a passage near the end before attempting to review what led up to it. Sir Josiah opened with a definition. " Economic progress," he said, " is the orderly assimilation of innovation into the general standard of life." Bearing in mind that " Economic " is used in its wide and not its commonly employed restricted sense, we do not see how this definition could be bettered. Man's power to assimilate for his own benefit, comfort, and contentment every advance of science and technology is the ideal at which to aim. If that assimilation does not take place quietly, if there are disturbances, as when the mob broke Arkwright's machines, or if what is called technological unemployment results, then and by so much there is a departure from economic efficiency. It is because these things happen, because innovations seem for the time being to have outrun man's capacity to benefit by them, that Sir Josiah was presented with the problem which he attempted to clarify, if not to solve. " It is," he said, " being commonly stated that scientific changes are coming so thick and fast, or are so radical in their nature and implications, that the other factors of social life, the intangibles of credit, the improvements in political and international organisations and ideas, are unequal to the task of absorbing and accommodating them, or else they present new problems which have no counterpart. If changes in social forms and human nature or behaviour cannot possibly be made rapidly enough for the task, then in that sense science may 'ruin' economic progress, and the world might be better served in the end if scientific innovation were retarded to the maximum rate of social and economic change." This quotation embodies the theme which Sir Josiah developed. One hundred per cent. economic progress can only be attained when a perfect balance between the rate at which innovations are introduced and the power to absorb them is reached. It is the difference in *tempo*, as he calls it, that causes the disturbances which technology is provoking in society at the present moment. Two kinds of balance have to be effected. The first is that " between two classes of scientific discovery, that which accelerates or makes easier the production of existing economic goods, and that which creates new kinds of economic satisfaction—the derivative and the direct." The second, " which is vital to economic progress and may be ruined by over-rapid innovation, is that between obsolescence and depreciation." Both these equations were analysed by the lecturer in detail. For the past hundred years the first kind of balance has been brought about automatically. Increased productivity has been met, on the one hand, by an increasing demand for the product produced, and, on the other, by the release of money for the purchase of other commodities—old or new. But " even if these two classes of innovation, direct and derivative, are in balance, the progress of absorbing them will give rise to economic 'growing pains,' and temporary dislocation of capital and employment, but the gains will rapidly outweigh the disadvantages. But when they are not in balance, the process is more painful, and the debit to be set against progress very much greater." This, we take it, is the kind of balance, or out-of-balance, which is the obvious cause of present unemployment. But in view of the fact that many desires and even necessities are unsatisfied in the world, it would not be fair to hold technological advances responsible for it. It is, we suggest, not innovation which is at fault, but rather that means to take advantage of innovation are out of gear. In other words purchasing power has not advanced *pari passu* with producing power. To the second kind of balance—that between obsolescence and depreciation—Sir Josiah devoted much attention. It is one of particular interest to manufacturers, but we can do no more than record two or three of the conclusions to which the lecturer was led. He found that " an over-rapid series of innovation may mean the scrapping or unprofitability of much excellent capital for very small marginal gains," that " the majority of modern innovation is of the type which does *not* pay the cost of obsolescence, and proceed by orderly and natural physical renewal or substitution," and that " no prices ought to be charged except on the basis of costs fully loaded with short-period obsolescence—this would prevent over-rapid substitution, economic only to a narrow range of people."

We should weary our readers if we attempted to condense into a few passages the remainder of an address which will certainly be studied with close attention by all serious economists. It must suffice to say that Sir Josiah discussed such matters as the place of leisure in economic progress; the power of " a socialistic organisation to obviate such of the maladjustments as depend upon gains and risks of absorption not being in the same hands"; and international relations, and foreign trade. Neither shall we attempt to make our own deductions from the arguments advanced in the address. Rather does it seem better to place Sir Josiah's own conclusion before our readers. It runs thus: " Economic life must pay a heavy price, in this generation, for the ultimate gains of science, unless all classes become economically and socially minded, and there are large infusions of social direction and internationalism, carefully introduced. This does not mean government by scientific technique, technocracy, or any other *transferred* technique, appropriate as these may be to the physical task of production; for human wills in the aggregate are behind distribution and consumption, and they can never be regulated by the principles which are so potent in mathematics, chemistry, physics, or even biology. Scientific workers may contribute much by sharing the problems of social science along its own lines, by giving a greater proportion of brilliant minds to this field, and by planning research."

The Growth of Scientific "Jargon."

At the British Association meeting at Leicester last week the alleged alarming growth of technical " jargon " attracted a considerable amount of informal comment and discussion. In certain quarters it was asserted that the obscure terminology adopted by numerous authors and speakers constituted a menace to the spread of scientific knowledge. The complaint is not merely that the general public is experiencing increased difficulty in following the papers and debates at the Association's meetings. The growth of " jargon," it is maintained, has now reached such a stage that authorities in any one branch of science are commonly at a complete loss to understand those in another, and even, on occasion, their brother specialists in the same branch. The trouble is said to be prevalent in varying degree in all scientific literature and discussion, and is not confined to the contributions made to the proceedings of the British Association. Typical of the views expressed are those of Professor B. W. Holman, of the Mining Department, Imperial College of Science, and Chairman of the Association of Scientific Workers. Professor Holman is an advocate for the use of " basic English " as devised by Mr. C. K. Ogden on lines first suggested by Jeremy Bentham. Ordinary communication in idiomatic English is, he says, possible by means of the 850 foundation words in the basic English vocabulary. To meet the requirements of science in general he would allow an addition of 100 words, while any particular science might be permitted to use an extra fifty of its own. The rapid progress of discovery and the rapid growth of terminology which has accompanied it have undoubtedly resulted in each department of science employing a language peculiar in many of its terms to itself. On broad grounds we must regret this development, and the passing of the days when a man of scientific intelligence could feel at home in half a dozen branches of study. But while our sympathies are entirely with Professor Holman and others who seek to establish the use of familiar English in scientific writings and discussions, our reason tells us that the development has been inevitable. The separation of the sciences by their adoption of different specialised terminologies must become ever greater as each cultivates its own field.

Science, consisting as it does of nothing but precision of observation followed by precision of thought, demands for the communication of its knowledge precision of expression. If it is to survive, let alone progress, it dare not employ loosely-defined terms. In at least nine cases out of ten, the definitions of common English words given in ordinary dictionaries are far too loose for scientific usage. The artistry of the poet and novel writer undoubtedly benefits from this looseness; it leaves room for the individual imagination of the reader to play among the shades of meaning. In the same spirit the artistry of the painter or sculptor is expressed in tone or line which by its lack of full definition and precision excites the beholder's personal interpretation. But in science there is no room for artistry and its appeal to the imagination. We have to present, not a painted canvas, but a photograph as sharp as it is within our powers to focus it. We have to speak, not in the faceted phrases of the poet or in the wilfully vague terms of the politician, but in words of trebly refined definition. In early days scientists expressed themselves naturally by means of words in common use. As their knowledge extended and their conceptions became refined it became essential to extend and refine their vocabulary. Expansion was achieved by the coining of new words or the adoption of foreign terms. Refinement of the existing vocabulary was effected by giving specially selected or restricted meanings to the common words of which it was composed. These two processes, the introduction of new terms and the refinement of the meaning of native words, are jointly responsible for the so-called scientific jargon of to-day. If the adopted or coined word constitutes jargon, then so, too, does the native word after it has been re-defined to suit the precise needs of science. Jargon, or, as the dictionary has it, "phraseology peculiar to a sect or profession," is created not by the words adopted, but by the act of attaching particular meanings to them. The familiar native word embedded in a scientific statement may not appear to be, but nevertheless commonly is, jargon or professional slang, just as certainly as the most patently and outrageously fabricated word. The sentence, "Stress is proportional to strain," is composed of nothing but simple familiar terms, but because of the closely defined meanings attached to the first and last words it is professional jargon of a high order, so high, in fact, as to make the statement utterly meaningless to the uninitiated. To-day it is the adopted or coined word which is singled out for attack as jargon, but it is not so many years ago in the history of science since the associated practice, the refinement of the meaning of common or native words, gave rise to precisely the same difficulties and protests. Difficulties were created when scientists first began to use the word "heat" in its modern sense as implying a quantity of energy. They were faced with protests that common usage—as in "summer heat" and "blood heat"—associated the word with another conception, the conception of temperature. In 1880 Sir William Thomson admitted the difficulty, and recognised the justice of the protest. To meet the situation he proposed that the term "caloric" should be retained—in spite of the abandonment of the materialistic theory of the nature of heat—to denote definitely "the measurable essence of heat"; that is to say, that quantity which could be measured by means of a calorimeter as distinct from the factor measured by a thermometer. Scientists to-day use "heat" in the sense of Kelvin's "caloric," but by giving it a precise and restricted interpretation they have added it as a word to their vocabulary of jargon in exactly the same manner as they have done by coining and defining "entropy." Frequently, as with "heat," the scientist makes jargon of a common word by simply selecting one of, possibly, half a dozen meanings attached to it, and rigorously excluding all the alternative definitions. This conscious process is eminently rational, and indeed is essential in view of the paramount necessity for precision and freedom from ambiguity. Occasionally he may appear to adopt a word with only half an eye on the dictionary. The engineer, for example, uses "fatigue" as applied to metals in a sense remote in some vital respects from its common significance. Doubtlessly, the term seemed, in its familiar meaning, an excellent one to describe the phenomenon to those who first observed it. We now know that it is really inappropriate, but we continue to use it. It is, in fact, to-day jargon just as much as would be "lassitropy," had such a terrible word been invented to designate the phenomenon. Many other common words adopted by scientists have become jargon, in a similar manner, with the passage of time and the accumulation of knowledge concerning the conceptions to which they give names. The formulation of Hooke's Law and its logical interpretation have led to a complete inversion in science of the dictionary definition of "elasticity." The use of the word "inertia" as a synonym for "mass" is as clear, and, on reference to the dictionary, as extraordinary a case of jargon as one could hope to find. Yet behind this usage lie centuries of observation and reflection and the culminating wisdom of Newton's First Law.

The growth of scientific knowledge must be accompanied by an equivalent growth of scientific terminology. The discovery of new phenomena and the establishment of new conceptions would produce an ever-widening circle of confusion if freedom to introduce new names were denied us. The most completely jargonised branch of science is mathematics, and it is certainly the most orderly. It is undoubtedly true that the use of jargon restricts or prevents the understanding of a scientific subject by anyone unversed in its meaning. The instruction of the uninitiated is, however, not the prime aim of science. Its object is the progress of natural knowledge, and the first essential towards such progress is the labelling or naming of the facts which are observed and the conceptions concerning them to which reflection gives rise. How far, it may be asked, would the theory of relativity have progressed if its exponents had been compelled to express their ideas by means of the same words as those employed in the exposition of the Newtonian philosophy. In what condition would botany and zoology be to-day without the vocabulary of deliberately invented classical jargon by which the species and varieties of plants and animals have been named systematically? The engineer has his own jargon and supplements it with that of most branches of science. Among electrical engineers its use is particularly evident, but the two older branches employ it almost as liberally, although perhaps less ostentatiously. Is it conceivable that engineering could have reached its present stage of development if engineers had from the outset been confined to a vocabulary of 850 basic words? Can we believe otherwise than that any attempt to reduce the magnitude and free growth of the language employed by engineers and scientists will have a definitely restrictive effect on their work and be responsible for confusion rather than progress? Science, directly or indirectly, is to-day the most powerful factor leading to the introduction of new words into common use. If its operation in that direction were artificially stopped our language would almost wholly cease to grow. Simultaneously, science itself would, it is certain, lose its vitality and become, like Cæsar's "Commentaries," a book that is finished. It would become supremely fit for exposition to a juvenile audience, but as a force moving the world it would be dead.

SIXTY YEARS AGO.

THERE is, or used to be, an Army phrase, "All Sir Garnet," employed to express the fact that everything is ready and in order. The phrase honours the memory of Sir Garnet (Viscount) Wolseley, and his ability to organise and carry through successfully difficult operations in many lands. Sixty years ago he was about to proceed on a campaign in Ashanti, which, although ultimately ineffective in securing the objects desired, brought him renown and high reward for the skilful way in which he conducted it. The King of Ashanti had refused to surrender to the British Government four Europeans whom he held prisoner. In January, 1873, he crossed the river Prah, the boundary between his territory and the British Gold Coast Protectorate. Somewhat leisurely, the home Government decided to punish him. Parliament voted £800,000 to cover the cost of the expedition, and Sir Garnet was instructed to take command of it. In our issue of September 26th, 1873, we described and illustrated the artillery equipment which was being provided for the campaign. We noted that the selection of the artillery and, indeed, the arrangements for the whole expedition had been left in the commander's hands to an extent which was unusual in military undertakings. The main equipment chosen by Sir Garnet consisted of a four-gun Howitzer battery with 1800 rounds of ammunition; two Gatling guns, and a quantity of small-arm ammunition, "exceeding the total number of rounds fired in the Russian War." Sir Garnet was given for the Howitzer battery the choice of either the 4½in. bronze smooth-bore Cohorn gun, or the more modern 7-pounder steel rifled gun. Both patterns were muzzle loaders. He selected the older smooth-bore pattern, on account of its simplicity, but we criticised his choice on the score that it was heavier and less accurate than the rifled gun. A special design of carriage was produced to meet the needs of the campaign in the almost untracked jungles of Ashanti. It was devised by Colonel Field and was designed and manufactured within a fortnight at the Royal Carriage Department. The carriage had a particularly narrow track, 2ft. 4in., to permit it to move along tracks not more than 3ft. wide. The Gatling guns were adapted for mounting on carriages of the same design instead of on the normal field carriage with a track of 5ft. 2in. Included in the equipment for the expedition were two "steam sappers," provided with wheels which could be adapted either to traverse soft ground, or, by inserting pegs in their tires, to ascend very steep slopes. Sir Garnet landed at Cape Coast Castle on October 2nd, 1873. He found 40,000 natives in arms against him. After severe fighting at Amoaful his army entered Coomassie on February 4th, 1874. It remained there only two days, for it was necessary to return to the coast before the rainy season set in. The capital was, therefore, set in flames and the army began its retirement. On the return march envoys from the King overtook it and concluded a treaty with Wolseley embodying all the British requirements. That treaty was, however, from the first, almost a dead letter. Under King Prempeh, the Ashanti nation continued to disturb the hinterland of the Gold Coast colony. The whole work had to be done over again. On January 17th, 1896, Sir Francis Scott, with a mixed British and native force, entered Coomassie and deposed Prempeh and his principal chiefs. Four years later the natives rose in rebellion and besieged Sir F. Hodgson and a garrison of 700 in Coomassie fort. Faced with starvation, 600 of the defenders managed to cut their way through to the coast. The remainder were eventually relieved by an expedition under Colonel Willcocks after a siege lasting nearly three months. On December 28th, 1900, the last of the rebels remaining in the field were captured, and in September of the following year, Ashanti was formally annexed to the British Dominions.

OIL FROM COAL.

ON Tuesday, September 19th, it was announced that orders had been placed in Sheffield by Imperial Chemical Industries, Ltd., for the plant required for the 100,000-ton per year hydrogenation installation which is to be built at Billingham-on-Tees. The orders, which amount to close upon a quarter of a million pounds, are mainly for forgings and other parts in highly specialised alloy steel, and will be executed by the English Steel Corporation, Ltd., and Thomas Firth and John Brown, Ltd. The two firms have agreed, in view of the special character of the work, to co-operate in solving through their joint technical staffs and laboratories any problems which may arise in forging and machining. It is anticipated that the work will occupy seven to eight months, during which the forges will be fully employed. Some of the largest forgings will weight over 100 tons and stainless steel will be used for pipes and valves.

METRIC UNITS OF VOLUME.

THE Chemical Divisional Council of the British Standards Institution has decided that in all British Standard Specifications prepared for use in the chemical industry in which reference to metric units of volume is made, the unit to be employed shall be the millilitre (abbreviation ml) in preference to cubic centimetres. For example, the millilitre has been adopted as the unit in terms of which British Standard volumetric glassware shall be calibrated, and as the unit to be employed in the description of analytical methods. The decision to adopt this unit was taken after careful consideration, involving a detailed study of the history of the metric units of volume and of current practice.

A similar recommendation was made by the Joint Committee for the Standardisation of Scientific Glassware in 1924, and has since been adopted in many important publications. Some journals, however, still retain the use of "c.c." The British Standards Institution considers that the general use of the millilitre in all journals is highly desirable. It is, therefore, hoped that editors of scientific journals and publication committees of scientific societies will give favourable consideration to the above recommendation, and, where this has not already been done, introduce the use of the millilitre into their publications at the earliest opportunity.

THE PORT OF LONDON.

ACCORDING to the twenty-fourth annual report of the Port of London Authority, recently issued, the total net register tonnage of vessels using the port during 1932 was 53,903,886 tons, against 56,074,556 tons for 1931, a reduction of 3·3 per cent. There was, however, a more serious decline in the volume of imports and exports, the total value being £409,371,000, which is £83,029,000, or 16·9 per cent., less than that reported for 1931. In the Authority's financial year, which ended on March 31st, a slight increase in both export and import tonnage was shown. There was also a small decrease in the net register tonnage of vessels liable to river duties, but an actual increase in ships engaged in coasting trade. The export trade handled by the Authority on the dock quays totalled 495,589 tons, which was a decrease of 21,887 tons compared with last year's figures. The more important works carried out by the Authority for the maintenance of its undertaking included extensive lock gate repairs at certain docks. At the Royal Albert Dock the quay cranes were overhauled and repaired, while at both the Royal Albert and King George V. docks, underground cables were substituted for overhead cables. During the year no less than 1,142,230 cubic yards of material were removed from the river in order to maintain and to deepen the navigation channels, while the quantity of mud removed from the various docks during the same period totalled 1,081,466 cubic yards.

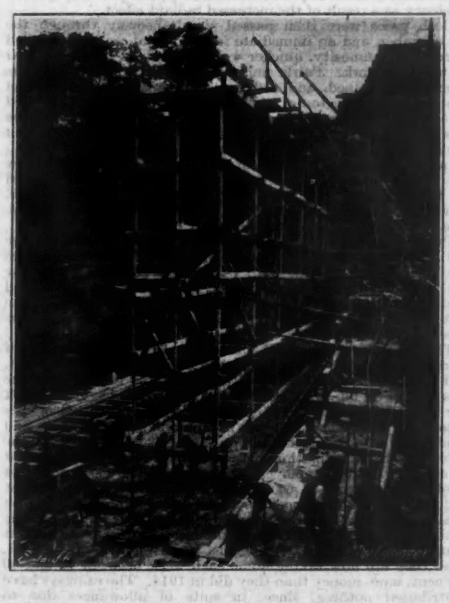
THE RYBURN DAM UNDER CONSTRUCTION AND COMPLETED

The Ryburn Reservoir.

◆

PRIOR to 1877, the city of Wakefield was supplied by a water company which pumped water from the river Calder below the town. What sort of standard of purity there was is doubtful, but it seems probable that it was low. At any rate, in that year the Corporation bought out the company and started the construction of the Ringstone impounding reservoir and other works on the Rishworth Moors, together with a storage reservoir at Ardsley. The new supply was inaugurated in 1887, and was both more plentiful and of better quality than the old. To keep pace with increasing demands—for Wakefield is in the midst of an industrial area, and was expanding rapidly—the Green Withens impounding reservoir was constructed at Rishworth in 1897, and five years later open sand filters at Kirkhamgate and a service reservoir at Lindale Hill were brought into use. Still further supplies were urgently necessary by 1917, and the Booth Dean dams and gauge basins were constructed at Rishworth between 1917 and 1922, and in the immediately following years the capacity of the Green Withens reservoir was increased by 25 per cent. By 1924, therefore, the water supplies for Wakefield and district had been brought to a level sufficient to meet all normal demands. Expectations of an expansion in demand, however, still remained to be met, and in 1924 powers were obtained to take water from the Ryburn valley, which lies to the north of the Rishworth Moors. The scheme included the construction of the Baitings and Ryburn reservoirs, a pipe line 20 miles in length, including a tunnel half a mile long, together with several bridges and additional filtration plant of the modern pressure type. On September 7th last, the opening ceremony of the new reservoir was performed by Councillor Charles Hopkinson.



STATE OF THE WORK IN SEPTEMBER, 1929

Above and on p. 284 we reproduce photographs showing a general view of the Ryburn dam, and its appearance at various dates during the time of its construction. This dam was designed by Mr. Clemesha Smith, the Corporation's waterworks engineer, and the work of construction was carried out under his supervision by direct labour. Curved in plan, it is of gravity section, constructed of concrete, has a full height from foundation to road level of 129ft., a length at the top of 600ft., and width at the base of 84ft. 6in. The volume of water impounded is about 220 million gallons. It is built across the Ryburn River just below the junction of that river with the Bogden Clough. Several novel methods were used in the construction of the dam. As usual, excavations for foundations were carried down until a suitable rock bottom was reached. But the cementation process was relied upon to reduce the depth of the cut-off trench. This trench was carried down a comparatively short distance. When the concrete was being laid within it, pipes were embedded therein to permit of subsequent boring at intervals of about 17ft. to depths between 100ft. and 200ft. At each end of the trench holes were bored for horizontal distances of 200ft. Cement grout was subsequently pumped down the holes at considerable pressure to force it into the joints of the rock. Usually, in excavation work of the class necessary for the construction of dams, 4in. diameter rotary drills are employed. The experiment of using 1⅞in. diameter percussive drills instead of the rotaries proved quite satisfactory, and brought about not only an increase of the rapidity at which the work was carried out, but a reduction by two-thirds in the drilling costs. Altogether, 150 holes were drilled, and 2278 tons of cement injected. The Francois Cementation Company, Ltd., of Doncaster, undertook this work.

As constructed, the upstream face of the dam is almost vertical, interrupted at its centre by the five-sided projection of the valve shaft. On the downstream side a stepped construction has been adopted. Nearly all the concrete was placed by gravity by means of chutes and tubes. Hopper wagons running on light gantries conveyed the concrete to those places which could not be reached by chutes. Altogether, a total volume of 60,000 cubic yards of concrete was required, crushed gritstone being obtained from quarries near each end of the dam above top water level. Shap granite concrete was used over the whole of the downstream face to provide a hard surface, and the upstream face was similarly treated for the upper 40ft. Six overflow bays arranged three on each side of the projecting valve shaft at the centre of the dam provide adequate capacity for dealing with flood waters. Beneath the valve shaft two outlet pipes, 24in. and 20in. in diameter, respectively, are fixed at about the level of the stream bed, while draw-off pipes at four different levels controlled by valves within the shaft supply the compensation water which the Corporation is under obligation to deliver into the stream. Use is made of this compensation water to drive a small Gilkes turbine supplying power for lighting and other services. A considerable proportion of the compensation water—about 400,000 gallons per day—is required by the Ryburndale paper mill, and an upward filtration plant on the Pennell-Wylie system has been provided to deal with it.

The cost of the dam, including such other incidental works as road diversions and filtration plant, has been approximately £235,000.

The Iron and Steel Institute.

No. I.

THERE are many who will share with the members of the Iron and Steel Institute their regret that the President, Mr. W. R. Lysaght, was prevented by illness from attending the autumn meeting, which was held between September 12th and 15th, at Sheffield. It is reassuring to know, however, that Mr. Lysaght has made a good recovery, and is now recuperating in Devonshire. A few months ago he celebrated his seventy-fifth birthday, and we are told that the illness from which he has just recovered was his first.

At the suggestion of Professor Sir Harold Carpenter, who presided at the meetings in Sheffield, a telegram was despatched to Mr. Lysaght expressing regret at his absence and good wishes for the future.

The first official function at Sheffield was a reception at the University on Tuesday evening, September 12th. The hosts and hostesses of the Institute's members and their ladies were Colonel H. K. Stephenson (Pro-Chancellor of the University), Mr. Newton Drew (Pro-Chancellor), and Mrs. Newton Drew, Dr. A. W. Pickard-Cambridge (Vice-Chancellor) and Mrs. Pickard-Cambridge, and Mr. and Mrs. Joseph Ward.

A very varied programme of social functions and visits to works was arranged, in addition to the meetings, by a very representative Reception Committee. It included a reception and dance at the Town Hall, by invitation of the Lord Mayor and Corporation, on Wednesday evening, September 13th; a banquet at the invitation of Sheffield industrialists on Thursday evening, September 14th; and on other occasions luncheons at the invitation of the industrialists. A special programme was arranged for the ladies during the afternoons, when the menfolk were visiting the many works which were open to inspection during the period of the meeting. The iron and steel industries of Sheffield and district have given a very clear indication of their appreciation of the work of the Institute by the readiness with which so many of the works have been thrown open to the members.

In addition, an exhibition of refractory materials manufactured in the Sheffield district was open for inspection at the University, and facilities were afforded for visiting the Sheffield station of the Institute's Corrosion Committee.

A Civic Welcome.

Assembling in the Mappin Hall at the University on Wednesday morning, the members and ladies were welcomed officially to the city by the Lord Mayor (Alderman Ernest Wilson). In his address of welcome, the Lord Mayor recalled that the Institute was founded in 1869, and was incorporated by Royal Charter in 1899. Its chief objects, he said, were the dissemination of knowledge of the science and technology of the manufacture of iron and steel, and the recording of progress in the art and metallurgy of iron and steel. The Institute was international in character, for of its 2000 members about 30 per cent. were resident overseas, and some seventeen foreign countries were represented in its membership. Thus, the members were continually enriched by contributions of a scientific or technical character from distinguished metallurgists of other countries as well as their own. The Institute carried on research work in association with the National Federation of Iron and Steel manufacturers and the Department of Scientific and Industrial Research. It had two important standing Committees, one studying problems of the corrosion of iron and steel, and the other the questions of soundness of steel ingots, under the chairmanship of Dr. W. H. Hatfield. Of the members of Council as constituted in 1905, when the Institute last met in Sheffield, under the Presidency of Sir Robert Hadfield, Sir Robert is to-day the only remaining active member of the Council. Sheffield was his birthplace, and his munificent gift of £5000 to the University recently was but one further evidence of his love for his native city. May this close association long continue!

Dr. A. W. Pickard-Cambridge, M.A. (Vice-Chancellor of the University), who added a welcome on behalf of the University, said that the University authorities always welcomed an opportunity of contact with those who were practically engaged in the application of the principles which were studied at the University, theoretically, perhaps, even more than practically. At the reception on the previous evening some of the visitors were able to gain some knowledge of the resources of the University, and the authorities desired that any criticisms or suggestions the visitors might care to make should be forthcoming, for nothing could help more than the criticisms of those who were practically acquainted with the subjects studied there and with the needs of the iron and steel industry. Professor Andrew, the indefatigable, insatiable, and irrepressible Professor of Metallurgy, would be the first to welcome any suggestion for the improvement of his Department. The authorities were anxious to do all they could to strengthen the bonds between the studies at the University and the profession, and had received the very greatest encouragement during the last two days from the noble gift made by Sir Robert Hadfield, who, throughout his life, had represented both the theoretical and practical sides in the best possible way. A man in Sir Robert's position would not have given such help on that and earlier occasions if the University was not trying to do the things it should do, and his gift would enable further experiments to be made in the development of metallurgy.

It was not very easy to define the relation between the University and the industry, but, roughly speaking, the University endeavoured to be, in the first place, a training ground to provide persons, already acquainted with the fundamental sciences, with a knowledge of which was absolutely necessary for the practical development of industrial methods, and it tried to supply the industries of Sheffield and elsewhere with a continuous stream of persons highly trained for the technical posts and for research work. It recognised that the theoretical side was fundamentally important and that there was nothing so unpractical as the neglect of theory. So far as its means would afford, it carried on research into metallurgical problems, and if there was any difference between the research carried on at the University and that carried on in the research departments of the works, it was, one supposed, that the practical needs were less immediately pressing at the University, so that the researchers could work more leisurely on fundamental problems and go over the field more often. Important discoveries often resulted from such work.

Another way in which the University tried to help industry was by carrying on an almost continuous consulting practice. Those who were not intimate with the University work could hardly realise how much of the time of the Professors and teachers there was devoted to answering problems put to them from outside.

The authorities hoped that the ties between the industry and the University would be strengthened by that meeting, and that they might regard all the members of that great conference as their best friends.

Professor Sir Harold Carpenter, in expressing thanks to the Lord Mayor and the Vice-Chancellor for the welcome they had offered, recalled that, as a young worker, he had attended the Sheffield meeting of the Institute in 1905, and that that meeting gave him his first introduction to the great men of the city. He recalled the venerable Mr. John Devonshire Ellis, and the world-famous Dr. Sorby at that meeting, and expressed his indebtedness for the inspiration he had derived from them. He also paid a tribute to Sir Robert Hadfield, and thanked him for his gift to the University, which, it was understood, was to be devoted exclusively to metallurgical work.

Great advances in engineering during the last twenty-five years, he continued, had depended ultimately on the development of materials and the extension of the range of properties they displayed. Development since 1905 had been accompanied by a steady demand for steels of better quality and greater diversity of properties. In particular, the automobile industry had been responsible for the extension of the use of alloy steels and for great advances in such fabrication processes as drop forging, tube-making and sheet pressing. Only in 1904 was the first paper on high-speed cutting steel published in the *Journal* of the Institute, the author of the paper being Mr. Gledhill. Although that was not an English discovery—or, at least, only partly—Sir Harold emphasised the fact that Sheffield, by the mere extent and quality of its knowledge, was able to take advantage of the discovery and to constitute itself one of the chief centres of the production and manufacture of that steel.

Discussing other developments in which the members of the Institute had played predominant parts, he mentioned first the work of the Committee on the Heterogeneity of Steel, under the chairmanship of Dr. Hatfield. The Committee was set up some years ago to try to improve the quality of ordinary mild steel. At the present meeting there would be presented the fifth report of that Committee, one of the most interesting ever presented to the Institute. Although the new scientific information contained in the reports was of the first importance, an even greater consideration was that, for the first time, the spectacle was presented in that Committee of a large number of members of one industry working with one aim in view. That had brought the work of the Institute into a new field and had shown the advantage of co-ordinated work of that kind.

Secondly, he mentioned stainless steel. So far as the chromium stainless steels were concerned, they were always associated with the name of Mr. Harry Brearley. It was doubtful whether the discovery of a really effective rust-resisting steel was ever contemplated by metallurgists before it was actually found. In 1910 Cushman and Gardner asserted that "the tendency to rust is a character inherent in the element known as iron, and will, in all probability, never be entirely overcome." That statement was strictly true, because the properties of an element could not be altered; but its implications bearing on the alloys of which iron was the base had been completely contradicted by subsequent events.

Then there were the creep- and heat-resisting steels. The first paper dealing with those metals was by Mr. G. H. S. Dickenson, of Sheffield, presented at the autumn meeting of the Institute in 1922. As the result of their development, the employment of metals at elevated temperatures had entered a new phase, and heat-resisting steels were giving satisfactory service at temperatures unheard of ten years ago.

RETIRING OFFICERS AND COUNCIL.

It was announced that the following would retire from the Council by rotation at the next annual meeting of the Institute :—

Vice-Presidents: Mr. A. Hutchinson, Mr. John Craig, C.B.E., Mr. E. H. Saniter.

Members of Council: Mr. E. J. George, Mr. J. S. Hollings, Mr. W. J. Brooke, Mr. F. Clements, Mr. H. C. Bond.

The first paper presented was on "Co-ordinated Heat Conservation at the Normanby Park Steel Works, Scunthorpe," by Mr. W. J. Brooke.

HEAT CONSERVATION IN STEEL WORKS.

In this paper the author discusses the problems which had to be solved in the search for economy at the Normanby Park Steel Works, Scunthorpe, the plant employed, and the results attained.

The problem to be solved was the practicability of utilising the necessary fuel coming into the works in the most efficient manner possible, all with a view to lowering the costs of the finished steel without primarily depending upon increasing the quantity of steel made—in other words, to obtain the utmost possible economy in production without having recourse to the purely dilution factor of big output.

The Normanby Park plant was designed in its original state by the late John Darby, of Brymbo, in 1909, and was completed and put into operation in July, 1912, and, therefore, celebrates its coming-of-age this year.

In the early history of the firm, it was the intention to utilise both coke-oven and blast-furnace gas as far as practicable, but for various reasons that was only partially carried out.

Prior to the new scheme coming into operation it was the practice to utilise gas as far as possible. Thus, the mixer and soaking and recuperator pits were heated with blast-furnace gas mixed with coke-oven gas when there was any to spare. Steam and most of the blast for the furnace was raised by means of blast-furnace gas. Even before the present improvements were installed, considerable economies had already been effected in the utilisation of gaseous fuel, and there being a ready market at that time for basic pig iron, a considerable excess of blast-furnace gas was made and constantly going to waste. Owing to the superfluity of this gas it is to be feared that sufficient effort had not been made to utilise it as efficiently as possible.

The author was definitely of the opinion that with the installation of modern ovens, coking at high temperatures, a much improved quality of coke should be obtained which, it was anticipated, would have the effect of reducing the quantity required per ton of pig iron.

He was also convinced that as the scheme in mind depended entirely for its success upon a constant supply of gas from the furnaces, steps must be taken to ensure them working with the utmost degree of regularity. The better quality of coke anticipated would form one factor, and the other must be the preparation of the ores to as nearly a constant uniformity as possible. To this end it was considered advisable to install a screening and crushing plant, to deal with the ores prior to charging into the furnaces.

Having arranged the regular supply of blast-furnace gas, it was decided to use a proportion to heat up the coke ovens, leaving all the rich gas for use where most needed. The first thing to be done was to investigate the approximate consumption of blast-furnace gas at the various points where it was used, and whilst this was not possible at that time with any degree of accuracy, sufficiently near results were obtained for calculations to be made. The results proved that in many cases gas was being used in a very extravagant manner and with disconcertingly inefficient results, but by the installation of recording meters at the soaking pits and other places valuable information was gradually accumulated. Improved burners were devised for use on the boilers, which effected remarkable savings.

Owing to the inefficiency of the boilers and the intermittent supply of blast-furnace gas, stoppages at the mill on account of steam shortage were frequent, and whilst for a long time it had been known that the boiler brickwork required repair, it had not been possible to do this owing to the inability to spare one or two boilers "off" for the requisite period of time. On account of the improvements effected by the new burners it was possible to do this, and the boilers were gradually taken off in pairs and completely rebuilt. The outside of the new brickwork was encased with steel plates, allowing for 2¼in. of insulating material between the walls and the plate binding. Immediately these boilers were put into operation after rebuilding, it was found that the air orifice to the burner was not large enough to burn sufficient gas. In the first case the air orifice was 6in. diameter × 7, equal to 197·89 square inches. This was increased to 8⅛in. × 7, equal to 360·792 square inches. This effected an immediate improvement, and is the design in use to the present day. The difference shown was due to the new brickwork having prevented the infiltration of air, which previously had helped to support combustion. Under the new conditions the whole of the necessary air was now supplied by the burner, with most beneficial results.

Blast-furnace Stoves.—One stove was attached to a turbo-blower fitted with a specially calibrated Venturi orifice for measuring the volume of air blown. It was found that almost perfect combustion was obtained with a minimum of excess air, whilst the waste gas temperatures indicate that the loss of heat to the stack was almost a minimum. An examination of the waste gases from the remainder of the battery of stoves showed that similar efficiencies were being obtained throughout, and it was considered that under these conditions there was no case for the installation of a more elaborate type of gas burner or checkerwork.

Regenerative Soaking Pits.—It was decided to find out how much gas per hour was being used in these pits. Recording meters were therefore installed, and by 1928—owing to the use of these meters—the quantity of mixed gas had fallen from 800,000 cubic feet to 563,000 cubic feet per hour. This reduction could be attributed almost entirely to the meter installation, as the accurate recording of the gas enabled one to devote closer attention to the settings of the air valve and chimney damper. The constantly fluctuating pressure of the blast-furnace gas made it very difficult to obtain higher efficiencies.

Recuperative Pits.—Here the most important item was to investigate the proposition of using mixed blast-furnace and coke-oven gases on the steel furnaces. Here a difficulty was met with. The ovens at the best rarely yielded more than 15 per cent. of surplus gas, and usually that was all required for use at the soaking pits. Recourse was had, however, to the week-end working of the steel furnaces, and two furnaces were fitted with the necessary gear to enable preliminary experiments to be carried out. That was only possible on the first charge on Sunday each week, and there was only enough gas for one furnace.

The blast-furnace gas was first of all put through the checkers, and the coke-oven gas was admitted into the uptake of the gas port. That was immediately found to be wrong; little mixing of the gases took place, and whilst the furnace roof could be melted with ease, the same could not be said of the charge. The next step was the admission of the gas into the regenerator chamber above the level of the checkers. That was an improvement, and several heats were made in this manner. Careful measurements of the hourly quantities of the two gases were made. Perfect admixture of the gases, however, was still not obtained, and difficulty was experienced in that the degree of luminosity usually found with producer gas was not obtained, and this created considerable difficulties in the use of the gas by the furnacemen.

It had previously been asserted that the rich gas must not be passed through the hot checkers on account of the liability of the hydrocarbons to become dissociated, but from a little consideration the conclusion was drawn that that was what was needed in order to produce luminosity, and probably greater efficiency as a result of the increased radiant effect.

Both gases were then passed simultaneously through the gas chamber, and an immediate improvement was experienced as regards luminosity, quicker working, and less wear and tear on the brickwork. Fairly uniform times of working the heats were now obtained, and a figure representing the number of heat units used per ton of steel made, which could be employed as a basis for future calculations, was obtained. That figure was undoubtedly on the high side, as the calorific power of the coke-oven gas was not high, being only some 460 B.Th.U., as against the 520 B.Th.U. or more expected with the new ovens. It included, however, the quantity of gas required for the manufacture of a number of grades of high-class steel, which invariably took longer in the furnace to manufacture. The figure thus taken was 6,600,000 B.Th.U. per ton of steel.

Previously, the blast-furnaces, using a very lean mixture of Lincolnshire stone, consumed about 32 cwt. to 33 cwt. of coke per ton of pig iron, but with the expectation that the sizing of the ore and improved coke would reduce this, it was calculated that 31 cwt. of coke per ton would be used. This gave the quantity of pig iron that would have to be made to create the necessary amount of gas.

The ultimate aim of all these changes—the reduction of working costs—has been achieved to a quite satisfactory point, and as an instance of this it is now possible to produce coke at a cost of 3s. 6d. to 4s. per ton less than the price of the slack per ton delivered at the ovens, after giving the usual credits obtained by the sale of sulphate of ammonia, crude benzole, and crude tar, at current market prices. Gas is credited to the extent of the participation of the oven gas in the displacement of coal previously employed, and varies with the amount of steel produced from 3s. 6d. to 4s. per ton of coke. From this it will be readily understood that basic pig iron of the very best quality is now being made at a cost that is less than anything achieved in Lincolnshire since the early years of the present century. The workmen at the blast-furnaces have not suffered, since they are now taking home each week between 70 and 80 per cent. more money than they did in 1914. The railways have contributed nothing, since, in spite of allowances due to de-rating, some 10 per cent. more is still being paid for the assemblage of the blast-furnace raw materials than was paid before the war.

DISCUSSION.

Mr. F. Clements (Member of Council), after congratulating Mr. Brooke and his collaborators on the courage with which they had faced the problem of reducing production costs, said an appendix to the paper indicated a production of 3866 tons of pig iron and an equivalent production of 4617 tons of steel. He felt quite sure, however, that that weight of pig iron was not absorbed in making the weight of steel indicated. Hence, in order to make the operations balance, Mr. Brooke had to assume a market for that excess pig iron; in so far as that assumption was made, the works were not in balance. Plants which had not the benefit of blast-furnaces, of course, had to depend on outside supplies.

The cost of the final product, of course, could be affected by the prices charged for inter-departmental services, and that led him to discuss the price of gaseous by-products utilised in the production of iron and steel. Coke oven gas was saleable at 9d. per thousand cubic feet, equivalent to 1·8d. per therm

(100,000 B.Th.U.), assuming that the calorific value of the gas was 500 B.Th.U. per cubic foot. The value of hot gas produced by modern gas machines could be valued at 1·67d. per thousand cubic feet, or 0·78d. per therm, that figure including depreciation, labour, and all other costs. A very conservative estimate of the value of blast-furnace gas was 0·5d. per thousand cubic feet or per therm, assuming that the gas had a calorific value of 100 B.Th.U. per cubic foot. If, therefore, one compared these various classes of gaseous fuel against the hot machine gas as a basis, the value of coke oven gas on a heat basis was 3·9d. per thousand cubic feet. Therefore, if Mr. Brooke charged the gas to his open-hearth plant at a figure greater than 3·9d. per thousand, the open-hearth plant was suffering; if, on the other hand, he was not charging the gas in at a market value of 9d., then the coke oven plant was suffering. Bearing in mind that it was worth his (Mr. Clement's) while as an ordinary consumer in Sheffield to use gas for heating and cooking, at 2s. 8d. per thousand cubic feet, and that the gas supplied was coke oven gas, it became evident that the use of coke oven gas in an open-hearth furnace at the low price he had indicated earlier resulted in wastage of a national asset, for there were other markets for it and the community would benefit greatly if it were sold in those markets. Again, he discussed the utilisation of blast-furnace gas in gas engines for the generation of electric power (a furnace with an output of 1000 tons of pig iron a week would supply 6000 kW), and said that if a profit of 0·05d. per unit of electricity could be made the value of the blast-furnace gas was at once enhanced to 3·5d. per thousand cubic feet. If that were so, he was almost tempted to say that it should not be used for low-grade services. He could not be persuaded that Mr. Brooke's mixture of coke oven gas and blast-furnace gas was as good as the normal product of a gas machine for use in open-hearth furnaces.

These considerations led Mr. Clements to suggest that, in order to ensure the proper utilisation of coke oven and blast-furnace gas throughout our industries, there should be cokers of large output centred in appropriate centres using blends of coal which would produce uniform coke possessing the best properties, that the coke ovens should be fired with gas made from breeze out of the coke, and that the coke oven gas should be fed into a national grid for use by the community. He did not think there was any real case for the combination of cokers with blast-furnaces, but he visualised a national blast-furnace industry, blast-furnace activities being concentrated in appropriate places at which large outputs would be attained, and the gas used for power generation. If there were an output of 10,000 tons of pig iron per week the gas produced would serve a power station and would provide 60,000 kW continuously, and that could be fed into the national electricity grid. He saw no connection between blast-furnaces and open-hearth furnaces, and saw no reason why the steel plants of the country should not be located with reference to their markets. When allowance was made for cost of transport of materials one could still show a handsome gain. He claimed with confidence that such an orientation of operations would give a commercial efficiency unequalled in any other country in the world. Such a scheme was Utopian, but not impossible.

Mr. F. W. Harbord (Past President), discussing the operation of the coke oven gas in the open-hearth furnace, said he believed Mr. Brooke was right in saying that one must use a higher temperature, and suggested that his difficulties of foaming were due to high hydrogen content; he seemed to be right in assuming that that was due to moisture.

Discussing Mr. Clement's suggestion that there should be a central grid for blast-furnace and coke oven gas, he pointed out that if such gas were fed to a grid it was necessary generally to make a contract. He believed there had been some difficulties in that connection in Germany. If one had contracted to supply to a grid a definite quantity of gas per week, and if trade were bad, one might have to run the blast-furnaces as producers merely to supply gas to the grid. That was a very serious obligation for any industry to undertake, and he was inclined to think that the future of the industry was far more likely to be preserved by making each unit independent and of a reasonable size, which could be controlled by one man.

Mr. James Henderson (Vice-President) joined issue with Mr. Clements with regard to the establishment of a gas grid, for it was quite apparent, from the evidence given to the Area Gas Committee in London—of which he was a member—some time ago, that the cost of distributing coke oven gas was so considerable as to limit very definitely the area which could be supplied profitably. He believed also that that had been the experience in Germany.

Commenting upon a statement in the paper that the regenerative soaking pits were fired with blast-furnace and coke oven gas, he suggested that such use of coke oven gas was possibly not the most economic. It was the experience at Frodingham and Appleby that the type of furnace referred to could be served very well by blast-furnace gas. A coke consumption of less than 26 cwt. per ton of basic pig iron produced, which was the consumption of two furnaces mentioned in the paper over a period of months, was excellent. Figures approaching that had been attained at times at Frodingham and Appleby. The low figure mentioned in the paper was probably due to the excellent coke used and to the excellent crushing and screening of the ores. The coal consumption of 1·5 tons per ton of steel, which was the end figure given in an appendix, was excellent. He did not know of anything equal to it in this country, and doubted whether there was anything much better on the Continent. He pointed out, however, that the quantity of pig iron made was 3885 tons and the ingots made represented 5370 tons. There appeared to be a usage, if all the pig iron were used, of about 70 cwt. So that actually the consumption of 1·5 tons of coal appeared to be based on the tonnage of ingots, and that quantity represented a certain amount of raw material which had not gone through the blast-furnace.

Mr. Brooke, in a brief reply to the discussion, said he disagreed absolutely with Mr. Clements concerning the supply of gas to the grid. With regard to coal consumption, the figure of 1·5 tons of coal per ton of steel had been beaten during some weeks and that figure had included all the coal used on locomotives, cranes, and so forth, so that the figures given in the paper represented practically common practice at the works. Mr. Brooke indicated that he would reply in greater detail in a written communication.

A paper entitled "Notes on the Utilisation of Blast-furnace Gas," by W. B. Baxter, was then taken. The following summary is taken from the text:—

BLAST-FURNACE GAS.

Blast-furnace gas is no longer looked upon as a waste product of the blast-furnace, but as an essential factor in the working economy of a combined plant. It is important, therefore, that this valuable product be conserved and used as efficiently as possible.

How this is being accomplished at Appleby is indicated by the test results which form the seven Appendices to these notes. The tests are chosen as typical examples of the utilisation of the blast-furnace gas for various purposes. They were not made under ideal or staged conditions to demonstrate maximum efficiency, but to show what was happening under present-day practice in order to detect where improvements in working might be achieved.

The data obtained from the tests collected in these Appendices justify the policy of the use of blast-furnace gas and the gradual elimination of coal. The effect of this policy is well shown by the large reduction in the use of solid fuel at the Frodingham works. The following figures show the consumption of solid fuel expressed in cwt. per ton of ingots produced. They do not include blast-furnace coke, but do include the solid fuel used for all other purposes in the iron and steel works such as coal for steel furnaces, boilers, locomotives, travelling cranes, and all the smaller consumers:—

1913	..	17·2	cwt.	of coal	per ton	of ingots
1924	..	10·65	,,	,,	,,	,,
1928	..	7·95	,,	,,	,,	,,
1933 (half year to June 30th)	..	7·13	,,	,,	,,	,,

The Appleby blast-furnace and steel plant has benefited from the experience gained at Frodingham, and the total consumption of coal for all purposes for the first half of the year 1933 amounted to 4·61 cwt. per ton of ingots, which figure includes the coal used in the melting shop for the production of ingots, namely, 3·35 cwt.

DISCUSSION.

Mr. F. H. B. Gough, commenting upon a statement that in the first half of 1933 the amount of coal used per ton of ingots was 7·13 cwt., asked what was the total amount of coal used in the production and the rolling of the ingots. One assumed that it would be in the region of 36 cwt. or 37 cwt.

Mr. A. F. Webber (National Federation of Iron and Steel Manufacturers) referred to some curious features in the boiler figures. It might seem hyper-critical, he said, to suggest that there was anything wrong with a boiler showing an efficiency of 83 per cent. on test, but the temperature at which the flue gases left the boiler, 347 deg. Cent., seemed abnormally high, being more than 300 deg. Fah. above the temperature of the water in the boiler, so that it seemed that there was something wrong with the heat transmission in the boiler. Again, the economiser installed provided only some 40 deg. Fah. rise in the feed-water temperature, and he questioned whether the expense of an economiser was justified for so small a rise. Perhaps that could be effected with exhaust steam, in which case the flue gases, at present passing through the economiser, could be used to preheat the gas. If that were done, the gas temperature would be about 140 deg. Cent., the combustion conditions in the furnace would be markedly improved, heat transmission would be very much higher, and it was almost certain that the overall efficiency would be still further improved by the reduction of the heat loss in the waste gases. With a boiler of that description, test efficiencies of 88 to 90 per cent. ought to be practicable, and blast-furnace gas was probably about the best boiler fuel there was.

Mr. Baxter, replying to the discussion, said that the excess air was something like 220 per cent., and that figure was arrived at by analysis. The figure was due to air leakages and as there was a draught in the chimney it did not appear to alter the balance very much. Replying to Mr. Webber, he said the efficiency of 83 per cent. was so far ahead of that usually attained at iron and steel works that perhaps those responsible at Frodingham had been too easily satisfied. He had not the slightest doubt that several refinements could be made which would increase the efficiency of the boiler. One boiler was fitted with an economiser and another with an air preheater, and the efficiency of both of them was round about 83 per cent.

The following papers were taken as read, but there was no time for oral discussion:—"Some Factors Leading to Greater Production from a Steel Furnace," by Arthur Robinson; "The Effect of Tin as an Impurity in Mild Steels," by Professor J. H. Andrew and J. B. Peile.

The meeting then adjourned until Thursday.

VISITS AND EXCURSIONS.

The city of Sheffield, in which the members of the Iron and Steel Institute recently held their meeting, has two reputations. One, for smokiness, is undesirable. The other, dealing with its manufactures in cutlery, steel and iron, and in particular with alloy steels, is recognised over all the world. In consequence, and in spite of the smoke which, in this year of depression, was not as much in evidence as it should be, the city is a Mecca to which every metallurgist and engineer must sooner or later make a pilgrimage. The very approach to it, by rail at least, is a delight. Apart from such evidences of industry as the darkening sky, the host of chimneys, the great bulk of blast-furnaces, and the banks of boilers standing in the open air convey, the traveller may peer at times into the very heart of things, and catch glimpses of glowing metal on its way to the rolling mills or being moulded to form beneath the hammer.

That Sheffield can hardly be called a beautiful city is of less concern than that it is a highly industrial one. To pass through it by rail, even to spend an hour or two in its streets, conveys the impression that far from being a city it is no more than a collection of works gathered together by reason of some geographical or other advantage of the site. Modification of such first impressions is necessary on closer acquaintance. Sheffield is neither so smoky nor so ugly as it is sometimes painted, as those members of the Iron and Steel Institute—surely a small minority—who had not visited the city before discovered. Sometimes the seemingly haphazard collection of shops approaches the picturesque. The works of Samuel Osborne, as seen from the viaduct, might be taken as an example; and the city contains a number of fine buildings, including the new City Hall, in which the citizens take great pride.

If Sheffield itself is largely a collection of works erected without thought of beauty, and attractive in certain lights only by some freak of their haphazard arrangement, it has the compensation that, in the words of Lord Palmerston, it is "A black picture set in a golden frame." The countryside around it, and particularly over the county border into Derbyshire, can be reckoned as one of the best districts in England. A journey of less than half-an-hour by train brings the jaded worker to a country of wide hills and valleys, to stretches of high moorland and fresh winds untainted by smoke. Having previous knowledge of Sheffield, it was here that we elected to stay for the duration of the visit of the Iron and Steel Institute, although the programme arranged gave us little leisure to do more than enjoy the immediate prospect from the windows of the hotel.

Officially proceedings opened with a reception by the University of Sheffield, Department of Applied Science, St. George's-square, at 8.30 p.m. on Tuesday, September 12th, but the honorary secretary's office in the same building had been open for some hours previously. From that time onwards the University building became the temporary headquarters of the Institute. Meetings of this kind are a curious and pleasing mixture of business and pleasure. There is something of the holiday spirit about the members, so that the business side, that of the reading and discussing of papers, is not taken too seriously. Following the welcome to the Institute by the Lord Mayor of Sheffield and the Vice-Chancellor of the University, only those with some particular interest in the subject under discussion, or with a highly developed sense of duty, attended the meetings in the Mappin Hall. Even so, the hall was always comfortably full. Many members, however, decided that since both papers and discussion would be printed and published in full, and could therefore be examined at leisure at some future date, the opportunity to see the city of Sheffield should not be missed. The official badge, a small medallion bearing the arms of Sheffield, surrounded by the words "Iron and Steel Institute, Sheffield, 1933," was therefore to be seen around all places of interest in the city during the morning.

At the invitation of Sheffield industrialists, members and ladies lunched, on Wednesday, at the Royal Victoria Hotel, at 1 p.m., and subsequently parties were made up and conveyed by charabanc to various works in the city, which included those of the English Steel Corporation, Ltd., Steel, Peech and Tozer, Ltd., Staveley Coal and Iron Company, Ltd., Corporation Electric Power Station, Walker and Hall, Ltd. (silversmiths and cutlers), Edgar Allen and Co., Ltd., Sheffield Coal Company, Birley, Brown Bayley's Steel Works, Ltd., Darwins Ltd., B. Huntsman and Co., Ltd., and Markham and Co., Ltd., Chesterfield. Many of the ladies elected to join these parties, but a tour through the beauty spots of Derbyshire proved a more popular counter attraction. In the evening there was a reception and dance in the Town Hall, at the invitation of the Lord Mayor and Corporation.

The programme for the following day was much the same as that which preceded it. The quota of papers to be read was brought to a conclusion in the Mappin

THE WORKS OF HADFIELDS LTD., SHEFFIELD, VISITED BY THE IRON AND STEEL INSTITUTE

Hall during the morning, and after luncheon motor coaches were again available to take members to the works of Thos. Firth and John Brown, Ltd., Hadfields, Ltd., Park Gate Iron and Steel Company, Ltd., Sheffield Gas Company, Thos. W. Ward, Ltd., S. Osborn and Co., Ltd., Viners, Ltd. (Silversmiths and Cutlers), Low Temperature Carbonisation, Ltd., or Jas. Neill and Co. (Sheffield), Ltd. Personally, we chose, with about eighty others, to visit Hadfields' East Hecla Works. Sir Robert Hadfield himself met and accompanied the party round the works. One of the first matters to attract attention was an exhibit of shells. The penetration of armour by a projectile presents little difficulty so long as the angle of approach is nearly normal to the plate. If, however, as is nearly always the case, the angle of approach is oblique, the rear part of the shell is likely to be broken away during the process of penetration, so that when explosion subsequently occurs a free path for the gases is provided through the non-existent back of the casing, and the body of the projectile is not shattered. To overcome the difficulty, there is provided at the back a ring which may fracture and fall away, but within the ring there is a solid casing enclosing the explosive. In an address of welcome to the members by Sir Robert Hadfield that lies before us as we write, and contains some highly interesting reading, some figures of tests upon modern armour-piercing projectiles are given. A shell of 15in. or 16in. calibre can be made to pierce completely armour plate up to 16in. in thickness, not merely normally, but even with the plate inclined at angles up to 20 deg. and even 30 deg. In one particular case a projectile fired at a velocity of about 1750ft. per second passed through a 12in. plate in 0·0039 second, and was recovered unbroken. The amount of energy absorbed was about 25,000 foot-tons. The most extraordinary point is that over a cubic foot of metal had to be got out of the way in less than half a hundredth part of a second! As Sir Robert points out, the significance of such results is not so much their importance in war, as the fact that the skill, experience, and equipment necessary to obtain them is available in times of peace for the manufacture of industrial products.

It is obviously impossible for us to refer at length to all that the members of the Iron and Steel Institute saw at Hadfields. Several books could be written about the works. Some "high spots," however, may be mentioned. In the main steel foundry—see the illustration on the opposite page—which is 1200ft. long and 7 acres in extent and is claimed to be the largest in the world, plaques representing Faraday standing in a metallurgical laboratory with a furnace to his left and a bench, chemical reagents and the now immortal box of "Faraday" steel alloys to his right, were cast in the presence of the members and turned out perfect in every respect. Faraday, as Sir Robert points out, had a considerable connection with Sheffield, and several of his alloys were made in the city. The steel plant, which includes modern types of open-hearth furnaces and a battery of electric furnaces in a range of capacities from 1½ to 6 tons, one of which is illustrated opposite, was examined with particular interest. The suggestion was more than once made that perhaps in the future electricity may come into use to such an extent that the need of Sheffield for innumerable chimneys will not longer exist. That time is certainly not yet, for such furnaces are only suitable for highly priced alloys. Near the fettling shops is the grinding department that deals with the "Era" manganese steel castings, which are so tough that ordinary machining methods are almost impossible. Not quite, however, for we saw in the machine shops a large casting in this material being turned, and it was observed that the metal appeared to be "torn" off rather than cut. The operation is illustrated by an engraving on this page. Owing to the exigencies of time, it was impossible to include the forging presses in the itinerary, but the steam hammers were seen, and the rolling mills, occupying an area of about 5 acres, aroused considerable interest, especially, on the "dramatic" side, among the ladies. There are three mills all electrically driven. The largest is a 28in. blooming and finishing mill driven by a motor rated at 3200 horse-power and capable of dealing with a transient peak load of 11,000 H.P. When running continuously this mill can turn out 1500 tons of billets and other sections a week, handling ingots weighing 1½ tons each. The others are 14in. and 11in. bar mills. The 28in. and 11in. mills are illustrated opposite. Tea, provided by the firm, was thankfully taken by the weary party before dispersal.

TURNING MANGANESE STEEL

A long rest was not allowed them, however. At 7.30 nearly all gathered together again at the Cutlers' Hall for a banquet by the invitation of Sheffield industrialists. A quotation from Rudyard Kipling, made by Sir Robert Hadfield when proposing the toast of "The City and University of Sheffield," stands out in the memory :—

> "Gold is for the mistress—silver for the maid!
> Copper for the craftsman, cunning at his trade.
> 'Good,' said the Baron, sitting in his hall,
> 'But Iron—Cold Iron—is master of them all!'"

The words epitomise the attitude of Sheffield industrialists. To keep "Iron—Cold Iron" the "master" of them all, is their greatest concern.

On the following day, the last of the meeting, a special train left Sheffield at 9 a.m. to take the members of the Institute and their ladies to Scunthorpe. The London and North-Eastern Railway provided for this excursion the special new train we described in our columns on August 4th last. It is composed of open cars with tables on each side. Two seats—one might almost say chairs—are provided on each side of each table. The only criticism we heard made of the arrangement was that for a fat man the seats would be hardly wide enough. But men of such weight are in a very small minority. The riding of the coaches was all that could be desired. Arriving at Scunthorpe, two parties were made up; one, which we accompanied, to visit Lysaght Ltd., and the other the Appleby Iron Company.

The Lysaght works were originally built in 1912, but they have since been considerably extended. In our issues of July 22nd and 29th, 1932, we described fully and illustrated the coke oven plant, which has a weekly output of just under 5000 tons of coke, with the usual by-products of sulphate of ammonia, crude tar and crude benzole. As now arranged, the plant has become the first thermally balanced composite one in this country. There was none too much time in the morning available for the Iron and Steel Institute to see these works. A beginning was made by an examination of the blast-furnace plant. There are three small blast-furnaces, 18ft. diameter bosh by 13ft. 6in. hearth diameter by 70ft. high, and two larger furnaces, 20ft. diameter bosh by 14ft. 6in. hearth diameter by 75ft. high, the bosh angle being in all cases approximately 80 deg. One of the furnaces was being tapped at the time of our arrival, and the spectacular sight was much appreciated, particularly by the number of ladies that accompanied the party. The blast-furnace gas is conveyed from the furnaces to a large waterless gasholder with a capacity of 2 million cubic feet. A diagram reproduced herewith shows how it is subsequently used in conjunction with the coke oven gas.

"THE ENGINEER"

FLOW DIAGRAM OF BLAST FURANCE AND COKE OVEN GAS

So that the furnace plant might receive the attention it deserved, the firm went to the trouble of providing every visitor with a slip of blue glass. There are seven fixed furnaces and one 160-ton tilting furnace, all of which are supplied with metal from a 300 tons gas-fired mixer. Three of the fixed furnaces, 60-tonners, are of the Terni type, one is equipped with Wellman-Soward ports and the remaining three are 50-tonners. All are heated by means of blast-furnace and coke oven gas, and waste heat boilers are fitted. Some of the men found the rolling mills somewhat too warm for their liking. There is a passageway between the 36in. cogging mill and the 32in. finishing mill, and when both are in action the heat thrown up by the metal is certainly somewhat overpowering. Steam engines of the three-throw reversing type drive the mills and the exhaust steam passes into a battery of Rateau accumulators for the purpose of generating electric power and blast for the furnaces. Semi-finished material in blooms, billets, slabs, and sheet bars is produced. After the inspection of the steel plant had been concluded visitors were conducted through the coke oven plant, which, as we have already mentioned, has been previously described in our columns.

Luncheon, at the invitation of Scunthorpe industrialists, in a great marquee erected in a field opposite the Lysaght works, was a welcome interlude after the exertions of the morning. Both the parties joined together for the function, and great admiration for the manner in which the affair was conducted was expressed. The weather, too, conspired to make the visit a success, for the sun shone brilliantly. After luncheon the greater number of visitors divided into the original two parties, the first, which had been conducted through Lysaght's in the morning, going to the Appleby Iron Company, and the second to Lysaght's. Others, however, preferred to go to the Frodingham Iron and Steel Company, Ltd., the Redbourn Hill Works of Richard Thomas and Co., Ltd., or the Scunthorpe Steel Foundry of Thomas Firth and John Brown, Ltd. We chose the last-named as a fitting corollary to the steel works of the morning. Being, comparatively to the extent of the other works small, it was, too, particularly agreeable for an after-lunch stroll! Erected in 1918 for the steel foundry plant of John Brown and Co., Ltd., it was decided after the amalgamation of that firm with Thos. Firth and Sons, Ltd., to concentrate the steel founding activities (with the exception of stainless steel casting) at Scunthorpe. This foundry is therefore adapted for producing a wide range of alloy castings. On arrival at the works the party was first conducted to the pattern shop, which, though small, is well adapted to its purpose. Thence we went to the main building housing the moulding, finishing, and heat-treatment departments, together with the fettling shop. It consists of four bays, the largest of which has a length of 750ft. by a width of 60ft. The first matter of interest to be seen was the centrifugal casting of railway wheels, which have a rim of tough manganese steel, the rest being softer. The complete operation was observed. Touring slowly through the foundry, moulding machines and sand preparation plant were examined. As, however, one of the three 2½-ton Robert acid side-blown converters was in action, there was a distinct tendency to give other matters less attention than they deserved. Besides these three converters which are fed by three cupolas, from which the iron is poured into a ladle for transference, there is also a 4½-ton Heroult electric furnace used for the more expensive alloys. Heat-treating furnaces with their tanks for oil dipping and water hardening were next observed, and the tour was concluded with a walk through the fettling and machine shops. In the course of conversation we heard the complaint made that the customer is seldom willing to take the advice of the steel foundry either in designing his patterns or in the composition of the alloys. The opinion was expressed that the customer would suffer less disappointment if he gave the steel founder a freer hand. In this connection the story was told of the engineer, who, having had some slight trouble with the products of a steel foundry, suggested in sending in a repeat order that since he believed it had a hardening action, a "pinch" of silicon should be added to the mix!

For the last time the party was gathered together at 4.30 for tea, subsequently breaking up, some to travel back to Sheffield in the special train, others to go to Doncaster for trains north or south. For ourselves the meeting concluded with leave-takings on the platform of Sheffield Station.

(To be continued.)

A MODERN COKING PLANT.

THE formal lighting up of the new by-product coking ovens which have been erected at the Manvers Main Collieries at Wath-upon-Dearne, near Barnsley, took place on Tuesday, September 19th. The plant, which was started up comprises thirty ovens of the underjet twin-flue type, complete with coal and coke-handling equipment, coke screening plant, and by-product recovery plant, designed and supplied by Simon Carves, Ltd., of Cheadle Heath, near Manchester. When completed, there will be in all forty-five ovens with a daily capacity of 1000 tons of washed slack. The present rated capacity of the thirty ovens will be about 500 tons per day, and the coke product will be specially applicable for domestic and central heating purposes. The by-product installation includes two stills with a designed output of 10,000 gallons of motor spirit, and it is expected that between 3,000,000 and 4,000,000 cubic feet per day of surplus gas will be available for supply to local authorities for town lighting and for industrial uses.

The British Association.

No. II.

(*Continued from page 256, September 15th.*)

THE work of the Safety in Mines Research Board was the subject of an evening discourse to the members of the British Association on Monday, September 11th. It was accompanied by experiments and a cinematograph film.

Professor J. F. Thorpe, F.R.S., the lecturer, said the Safety in Mines Research Board is appointed by and reports to the Secretary for Mines, and is financed liberally from the Miners' Welfare Fund. Its experimental work is carried out at two research stations, viz., at Harpur Hill, Buxton, and Portobello-street, Sheffield, where it is in close association with the Department of Applied Science of the University. Both these research stations are under the direction of Dr. R. V. Wheeler, to whom Dr. H. F. Coward is Assistant Director. Falls of roof and haulage accidents are investigated by Major Hudspeth, Chief Mining Engineer to the Board. It was also mentioned, by way of introduction to the lecture, that the Board also works through a number of sub-committees of which the Explosives in Mines Research Committee, the Spontaneous Combustion Committee, and the District Support of Workings Committees, may be regarded as types.

Commenting on the importance of the work of the Board in regard to mine safety, Professor Thorpe pointed out that by far the greater number of casualties and fatal accidents in coal mines during the period 1922–31 were due to falls of ground and haulage accidents. Persons killed through explosions during that period numbered 521, whereas the deaths due to falls of ground and haulage accidents were 5199 and 2276 respectively. Nevertheless, the casualties due to the two main causes just named were mainly adventitious, and it was difficult to subject them to scientific as distinct from human control. On the other hand, the causes of explosions and their elimination could be made the subject of scientific investigation, and the fact that the terrible disasters of the past no longer occurred must be ascribed to the application of the knowledge which had been gained by scientific research and investigation.

The lecturer than described the way in which that has been done, and showed the many causes which might lead to the ignition of gas and the methods which were being taken to remove those causes. The experiments had been arranged at the Board's Sheffield Research stations by Dr. H. F. Coward and three members of the staff of the Board—Messrs. Hartwell, White, and Russell—were in attendance as demonstrators.

Briefly recounting the conditions of work in coal mines, Professor Thorpe said that explosions could be caused either by gas or coal dust, indicating at the same time how fire-damp was evolved from decaying vegetable matter—a process of bacteriological fermentation. He also explained that coal dust, if fine enough, formed explosive mixtures with air as dangerous as, or, in some respects, more dangerous than mixtures of fire-damp and air. Although little by little the various causes of explosions, of the initial ignition of fire-damp or coal dust, had been recognised and controlled, the aim necessarily was to eliminate them completely. Fire-damp was only explosive, however, when mixed with certain proportions of air, between the lower limit of about 5 per cent. and the upper limit of about 14 per cent. Good ventilation of the mine, therefore, was a primary safeguard against fire-damp explosions, and that had resulted in stringent regulations governing ventilation. At the same time, should the ventilation be defective, there were many potential means of ignition of fire-damp in the pit, such as lights, explosives, electricity, frictional sparks, and so on, and they all had to be provided against. Consequently, much of the experimental work on safety in coal mines that was being carried out in this country and abroad was directed towards safeguarding all possible means of fire-damp ignition.

Coal dust, which, during one period in the history of coal mining, constituted the more formidable danger, could be rendered harmless as an explosive agent, and credit for the discovery, and certainly for the practical application of the remedy—stone dust—was due to a Yorkshire mining engineer, the late Sir William Garforth. Although, however, the spreading of fine stone dust in a coal mine appeared simple, it was complicated by the fact that there was not a dead level of inflammability of coal dusts. Some coal dusts were much more inflammable than others, and required to be treated with a proportionately greater quantity of stone dust before they could be regarded as harmless. Wise mine managers treated the roadways of their mines with a quantity of stone dust considerably above that required by the regulations, and it could be said with some confidence that in this country the wide-spread disasters caused by coal dust extending small fire-damp explosions throughout the working of the mine, such as occurred in 1905–12, need no longer be feared.

Often enough, concluded Professor Thorpe, before proceeding with his experiments, the application of a remedy against an accident rested with the miner. Therefore, it was necessary to instruct the miner—who had shown himself willing to be instructed—as to the reasons for measures of safety—sometimes arduous—that he was called upon to perform, and as to the risks he ran if he neglected them. For that reason, the educational work of the Safety in Mines Research Board ranked equal in importance with its experimental work.

The experiments which followed included the propagation of flame in methane-air mixtures; the inflammability of coal dust and the effect of stone dust thereon; the ignition of methane in air by a heated surface and the effect of iodine on the ignition temperature; the ignition of fire-damp by heat of impact of handpick on rock; signalling with bare wires; clay and sand-clay stemmings; lamp testing; an experiment showing that a lighted cigarette does not ignite a 6 per cent. methane-air mixture, and illustrations of spontaneous ignition by means of pyrophoric iron.

The films showed a demonstration of a coal explosion at the Buxton research station and shot firing with clay stemming and sand and clay stemming. Finally, a number of lantern slides were exhibited showing total casualties in coal mines; total fatal casualties; and the effect of stone dusting on casualties due to explosions.

SHOE MACHINERY.

The first paper in Section G on Tuesday morning, September 12th, was by Mr. Joseph Gouldbourn, of the British United Shoe Machinery Company, of Leicester, and dealt with shoe-manufacturing machinery and some special problems in its design. The paper outlined the comprehensive character of the machinery and summarised categories of special machines developed for performing certain important operations of the many different kinds into which the manufacture of boots and shoes has become divided. In illustration of the peculiar problems which the designer has had to solve, special attention was called, for instance, to a stitching machine which will set a lockstitch reliably at a selected depth in a sole as much as ¾in. thick, while sewing 1000 or more stitches a minute; metallic fastening machines, comprising means for marshalling and delivering both headed and headless nails; a pulling over machine, with pneumatic mechanism for simultaneously inverting and delivering a number of tacks to an equal number of tack-driving mechanisms; a lasting machine for securing the upper to the insole by staples, which clinch themselves in the thickness itself of the comparatively thin insole; a sole edge burnishing machine, in which, while the sole edge is traversing across the tool, both are automatically adjusted to the dual sole curvatures by systems of feelers operating machine controls through hydraulic relays; and, lastly, a pattern grading machine embodying duplex pantograph mechanism.

It was demonstrated how development through succeeding years has made the original machine used in the making of boots and shoes more automatic, and, as an instance of improved production, it was mentioned that whereas sewing a welt to a shoe formerly used to be done by a quick craftsman in twenty minutes, it is now done by machine in eight seconds; whilst stitching a sole to a welt is done by machine in ten seconds, as against forty-five minutes by hand. The machines described ranged from large cutting-out presses weighing over 2 tons to small machines weighing only a few pounds. The complicated mechanism involved is such that the number of parts ranges from 1500 to nearly 3000 per machine.

Mr. William Taylor said that as the directors of the British United Shoe Machinery Company were modest men, perhaps he might give a little sketch of the development of the business of that company. When he himself first went to Leicester in 1887 there was a firm known as Pearson and Benyon, Pearson being a most ingenious designer of machinery for making boots and shoes. Benyon was also an engineer, who was trained under Webb at Crewe, but generally he was responsible for the organisation of the business of Pearson and Benyon, and together with Mr. Pearson had transformed the whole process of making boots and shoes. The result was that the firm at the present time made the majority of the machinery used in the industry, not only in this country, but in the Colonies and some other countries. When he first knew the shoe industry it was in a very primitive state, the operators working on the floor among all sorts of scraps of leather and rubbish, without any bench, and when one compared that state of affairs with the present modern boot and shoe-making factory, it should be remembered that the change was largely due to the work of mechanical engineers and the work which was originated by Pearson and Benyon. There came a time when Benyon went to America, and realising that certain machinery which had been patented by the Americans was vital to the industry, he linked his firm up with the big American Shoe Company, and since that time the company in this country had been a branch of the American concern. A glance round the factory of the British United Shoe Machinery Company reflected the genius of Mr. Pearson and his partner, and demonstrated the tremendous number of fundamental problems that had to be dealt with in the design of boot and shoe-making machinery.

UNEMPLOYMENT PROBLEMS.

Three papers were then read and discussed together, all of them relating directly or indirectly to unemployment.

Professor Miles Walker, under the title "Great Engineering Works of Profit as a Cure for Unemployment," dealt with some engineering projects which, he said, promised a fair return and would employ hundreds of thousands of workpeople. He also considered methods of finance, similar to those proposed in America, for enabling the people to purchase the things they had made or for contributing to the cost of the future wealth-producing projects.

Many of the proposals made in the past for the cure of unemployment, he said, entailed the expenditure of large sums of money on public works, such as road improvements and new parks. The first consideration in the minds of those who proposed those works was the spending of money so that wages might be paid to those brought into employment. The second consideration was the choice of some work which (but for the present urgency of finding employment) would probably be done at some future date. It was argued that in choosing the work to be done, we must not put someone else out of work. That way of looking at matters was entirely wrong. The main object should be to create as much wealth as possible with the least expenditure of money, and instead of employing as many men as possible on some particular job, one should employ as few as possible on that job, there being no limit to the number of men who could be employed, because there was no limit to the work waiting to be done.

The raising of money by loans or taxes to do work that was not pressing had the effect of increasing unemployment, because it took money from people who would otherwise spend it on things they wanted and put out of work the people who ordinarily would supply those things. Instead of getting real wealth (*i.e.*, things we needed), we got only prospective wealth, which we could not use immediately.

The work to be chosen in order to create real wealth could be divided broadly into two classes:—

(1) The manufacturing of machinery and facilities for creating the articles we needed; and (2) the manufacture of the articles needed.

Coming to the effect of our monetary policy on unemployment, he said that some people were in favour of inflation and some of deflation. In his opinion, sufficient emphasis was not put upon the difference between wise and unwise inflation. Money could be replaced by paper receipts for work done. When a Government printed money and paid it out in order to carry on a war or to carry out relief work which did not produce real wealth equivalent to the money spent, it was unwise inflation. When a Government, in order to get going large numbers of unemployed inhabitants upon work which created the wealth they needed, printed promises to pay for work done, it was wise inflation. Under good management, the promises could be redeemed by giving the worker the things he needed; and by the use of machinery and economical production it was possible to give to the worker a greater return for his labour than could now be bought for the money usually paid in wages. It did not matter how much paper money of that kind was printed and circulated, so long as the amount of permanent wealth created was as great as or greater than the equivalent of the money issued. None of the money need be permanent; it could be destroyed as soon as the promise to pay was redeemed by the delivery of the goods.

It had been obvious to all sensible people during the last fifteen years that the right cure for unemployment was to set the people to make all the things they lacked. But the blindness of those who controlled the situation had prevented even that most obvious solution being inaugurated. Had the control been in the hands of engineers, it was exceedingly probable that during the few years following the war the manufacture of all the things wanted by the people would have been started in this country and in the Colonies on an immense scale. Mass production methods would have been improved to such an extent and overhead charges reduced to such a small fraction of the total cost that we should have been able to sell all kinds of machinery and household utensils at low prices to the rest of the world. By setting them an example, we should have taught them to manufacture more of their own wealth, and, by whetting their appetite, given them the desire and ability to buy from us goods that they could not make themselves.

We had spent 200 millions on public works which had not appreciably increased our present wealth, and we were paying interest on the money borrowed.

The best alternative to that method was to carry out the plan he had outlined. But it might be difficult to absorb at once two and a half millions of people on activities directly connected with the production of their own immediate wealth. We must take a rather longer view, so as to comprise in the word "wealth" engineering works which prepared for an ever-greater production in the future of the things the people needed.

During the last twenty years many sane engineering projects had been brought forward—underground railways in large towns, river bridges, extensions of electric power generation and transmission, the change from tramways to Diesel-driven omnibuses, the change from steam-driven to Diesel-electric locomotives, especially of the type containing torque-conversion apparatus, on main line railways. In many cases the possibility of a large margin of profit could be shown; in many the margin of profit was not sufficiently enticing to stir the people to action, but under the right methods of finance the work could be usefully carried out.

Professor Miles Walker then discussed the openings for the manufacture of plant for the carbonisation of coal and the hydrogenation of coal products in Lancashire; a world demand for oil-engine-driven locomotives; the development of underground railways in our large cities; and the desirability of erecting a building 800ft. high on the Piccadilly site in Manchester. A building of that kind, he said, would have cost about three millions sterling, practically the whole of which would have been spent in the neighbourhood on steel stanchions, girders, and other building materials, so that Manchester, by using her unemployed and saving the dole, might have said that she obtained the building for nothing. The upper stories would have housed comfortably about 10,000 people under the most ideal conditions. The ventilating plant would have drawn in the air from a point 800ft. above sea level, and supplied all the occupants with fog-free air at a suitable temperature all the year round. The cubic capacity of that building would have been so enormous that it could have housed also the picture gallery and free library, and there would have been also valuable sites for shops all round on the ground floor. The return from rents, on the most reasonable basis, would have been more than £450,000 per annum. Thus, Manchester would have relieved unemployment, solved the housing problem for 10,000 people, provided a free library and picture gallery, obtained the building for practically nothing, and secured an income of nearly half a million sterling for all time. In addition, pictures of the beautiful building would have been published all over the world and advertised Manchester as a go-ahead town.

He referred also to Mr. William Walcot's project for straightening the bed of the Thames in London and utilising the present bed in a profitable manner; and the project for the utilisation of the space over our railways. That was engineering work mainly, as it would call for the manufacture of millions of tons of stanchions and girders. It would improve London architecturally, and provide splendid arterial roads.

LAND RECLAMATION.

"Sea Defences and Reclamation of Land from the Sea" formed the subject of the next paper, the author being Mr. M. Du-Plat-Taylor. It dealt with the subject from two aspects—(1) the protection of lands against the inroads of the sea, and (2) the reclamation of lands from the sea, both of which, said the author, were worthy of consideration at the present time from the point of view of the relief of unemployment.

Speaking of sea walls and breast works, it was pointed out that the type of wall with a vertical face was most unsatisfactory, because it was liable to be undermined by the undertow or backwash of the waves, and, therefore, it must have deep foundations, which resulted in its cost being nearly three times that of the stepped wall. The latter and more modern type of sea wall either consisted of a sloping wall or a stepped wall constructed of reinforced concrete and so designed that the energy of the waves was gradually dissipated and the water finally turned back towards the sea. Walls of that type had been adopted for protecting stretches of open coast, because they were actually not much more costly to construct than earthen embankments and were much less costly to maintain.

Dealing with reclamation of lands from the sea, a number of well-known instances were mentioned and the economic aspect was discussed to some extent. For instance, in the case of the reclamation by the Dutch Government of 555,000 acres of land in the Zuyder Zee, at a cost of approximately £60,000,000, or £108 per acre, it was pointed out that the amount realisable from the sale of those lands for agricultural purposes could not possibly recoup the Dutch Government for the capital expenditure, but in that case the scheme was regarded as a national undertaking which would provide accommodation and occupation for the expanding population. If the increase in trade and taxable values was taken into account, it might turn the scale.

Owing to the agricultural depression no reclamation scheme intended to provide agricultural land only could now succeed in this country, said Mr. Taylor, but reclamation for industrial purposes or for the combined purpose of disposing of some waste material and the provision of additional land fell in a different category. For instance, a large scheme of reclamation in the estuary of the river Tees had recently been carried out by the Tees Conservancy Commissioners by which an area of 267 acres of land on the Seal Sands was being reclaimed, by pumping on to it the material arising from dredging operations for widening and deepening the river channels. That scheme would provide industrial sites. The Dublin Port and Docks Board was carrying out reclamation to provide industrial sites on the north side of the channel by pumping sand dredged from the harbour and channels on to an area of about 80 acres.

Speaking of the cost of reclamation a figure of £15 to £30 per acre was mentioned as applying to some of the earlier schemes of the eighteenth and nineteenth centuries, where the area was enclosed and the water pumped or drained out, but at the present time in the most favourable circumstances the cost, he considered, to be more likely not less than £70 per acre, or even £100 per acre, without pumping. In the case of the Zuyder Zee the cost of the permanent works had been over £100 per acre apart from the cost of the initial dewatering and drainage pumping. The method of reclamation by enclosure and pumping was generally only suited to the provision of agricultural land which could not be brought into full cultivation for two years. The second method of reclamation, namely, by filling, could, however, yield a substantial profit. Areas flooded by the tides might be enclosed and the level of the land raised by depositing waste material on it, such as furnace slag or colliery waste. In that connection the author drew attention to the enormous quantity of dredged material which was deposited in the sea every year, and suggested the possibility of utilising it for reclamation purposes. For instance, the quantity dealt with annually by the Port of London Authority was 4 million tons, and whereas the cost of dumping at sea might be as much as 1s. 9d. per cubic yard, the cost of pumping ashore to a moderate distance with a reclamation pumping plant would not exceed 1s. per cubic yard, and often very much less.

Finally, Mr. Du-Plat-Taylor drew attention to the disposal of house refuse and sewage sludge in relation to reclamation schemes. In London 1,500,000 tons per annum of house refuse was disposed of by dumping it in great heaps upon land and burning it, the average cost of such disposal being 7s. 6d. per ton. Moreover, 3 million tons of sewage sludge was annually sent to sea from London to be dumped in deep water from hopper barges. It should not be impossible, however, to devise some means of disposing of this huge mass of material to a better advantage by using it to reclaim muddy foreshores and low-lying marsh lands in the Thames Estuary, making them suitable for agricultural purposes. It would, of course, be undesirable and useless to cover the land with a solid layer of wet refuse or sludge to a depth of 10ft. or more, but if the disposal of those materials was combined with that of dredged material it would be possible to deposit the refuse or sludge in a layer, say, 2ft. thick, and then blanket it with a layer of dredged clay or sand. That process could be carried out in alternate layers, finishing with a surface layer of clay or sand. Mr. Taylor recognised the objection to that scheme, but said he felt, nevertheless, that it was one which deserved further investigation.

SHIP CANALS.

The third paper was by Mr. Walton Maughan, and was presented by Professor Holman, of the Royal School of Mines, London. The object of this paper was to stimulate interest in the construction of shipping canals across this country—for instance, from the Mersey to the Humber, from the Tyne to Solway Firth, and from the Clyde to the Forth. It was explained that Mr. Maughan had spent many years investigating these schemes, and in addition to urging their national importance, both in times of peace and war, he advocated their construction as a means of providing employment. The Mersey–Humber Canal was estimated to cost £140,000,000, the Tyne–Solway Canal £36,000,000, and the Forth–Clyde Canal £52,000,000. It was suggested that these canals should be sponsored and controlled by the railways jointly, a special Transport Board being set up for the purpose. Another feature stressed was the great advantage they would have by diverting a large proportion of the ultra-heavy traffic now carried across country and to that extent would reduce expenditure on road maintenance. In support of the proposals, reference was made to the White Sea–Baltic Canal, which had been built by the Russian Government in the record time of twenty months; in that case, however, by forced labour. That canal is 227 kiloms. long. Reference was also made to the great development of the canal systems on the Continent in justification of the large expense which would be involved. Incidentally, the idea is to have these canals wide and deep enough to take battleships and, of course, ocean-going liners.

The President (Mr. R. W. Allen), in thanking the authors of the paper, reminded those who favour canals that the whole problem with such schemes was finance, and he doubted whether any schemes, however they might appeal as regards the relief of unemployment for the time being, would have a chance unless it could be shown that they were financially sound.

Commissioner Lamb, of the Salvation Army, who was called upon by the President, discussed Professor Miles Walker's paper, and expressed his regret that an engineer should have brought engineering into the realms of high finance. For goodness sake, he said, let engineers keep out of high finance and get on with engineering. Speaking generally on the proposals in the paper, he expressed the view that a better service to the nation would be done by concentrating upon overseas settlement rather than by spending large sums of money on works in this country which would only have the effect of keeping the present large population within these shores. Unless we took full advantage of the possibilities of overseas settlement, this country would be overwhelmed. Commenting on the remark by the President of the Association in his Presidential Address that science was one of the humanities, Commissioner Lamb said he hoped that soon humanity would become one of the sciences.

Captain W. N. McClean remarked, as regarding reclamation schemes, such as that of the Wash, that a point always to be borne in mind was the flooding of the rivers, and it might be that by giving extra capacity for the outlet of floods from rivers in the reclamation scheme, very considerable improvement might be effected from the flooding point of view. Generally speaking, water transport was considerably cheaper than rail transport, but he was not aware over what area of country that applied. After mentioning a case in which coal was carried by canal 40 per cent. cheaper than by rail, Mr. McClean commented on the manner in which road transport was competing with railways even in the transport of coal, owing mainly to the time taken in the return of trucks, which was usually seven or eight days, and from that standpoint one 5-ton lorry would carry as much coal, in a given time, as seven 10-ton railway trucks. Finally, he expressed doubts as to whether a big expansion of canals would be of any particular advantage to the country.

Mr. J. S. Wilson (Recorder, Section G), speaking of another form of reclamation, namely, carrying roadways over railway cuttings in populous areas, mentioned an instance in London where the cost of covering such a cutting amounted to the equivalent of £93,000 per acre, *i.e.*, £2 3s. per square foot, including all road surfacing, &c. Those figures were arrived at when costs were higher than at present, and possibly the figure to-day might be 30s. per square foot or £65,000 per acre. Such figures did not make such proposals very feasible.

Colonel E. R. Pratt, agreeing with the general principle that any works of the nature suggested in the papers must be productive, disagreed with the implication in Professor Miles Walker's paper that the efforts so far made were not in that direction. For instance, the electric "grid" was a great step forward in productive works, as also was the construction of wider and straighter roads throughout the country. At the present time it was possible to get money in London for developments in Rhodesia or Uganda, but not in this country, unless the profits were so great that they brought with them the risk of penal taxation. Frankly, concluded Colonel Pratt, he did not think any of the authors had produced a new suggestion which would help very much.

Mr. W. Maughan, in reply to the discussion, contended that the canal schemes he had suggested would be economically sound, and he based that view on the fact that water transport generally was much cheaper than road or rail transport.

Professor Miles Walker, whilst agreeing with Commissioner Lamb on the desirability of overseas settlement, said that was a question quite outside any engineering problem. He added, however, that he was in entire disagreement with Colonel Pratt that we should continue with such projects as the further development of roads now, because in his view we could not afford them, and must wait until times were better. At the present time the unemployed wanted houses, furniture, clothing, food, &c., and they should be set to work to make those things, because the wages earned would be put into circulation and stimulate industry in many directions.

Mr. Du-Plat-Taylor agreed that the cost of dredging and dumping would vary according to the conditions and said that the figures in his paper related to the case he had mentioned. Strictly speaking, reclamation had no effect on the question of the flooding of rivers, because each area should have its own drainage for removing the surface water, and so long as the channels were properly cleared there should be no difficulty from flooding.

The President, commenting on the remarks of Commissioner Lamb, assured him that every engineering project is inevitably bound up with high finance, and cannot be separated. It was always one of the most important considerations for the engineer. As to humanity becoming one of the sciences, he also reminded Commissioner Lamb that engineering and other employers to-day regarded the welfare and conditions of their workpeople as a first consideration. In that connection he mentioned the infinitesimal risks obtaining to-day in the case of men working under high-pressure for tunnelling work. He assured Commissioner Lamb that engineers, on the one hand, were bound up with finance, and, on the other hand, had one great object in view, namely, humanity.

(*To be continued.*)

Must Science Ruin Economic Progress ?[*]

By SIR JOSIAH STAMP, G.B.E.

ECONOMIC progress is the orderly assimilation of innovation into the general standard of life. It usually connotes a widespread sharing of new benefits, but is by no means inconsistent with some degree of uneven distribution of wealth or income, for in a non-socialistic community some disparity generally raises the standard of life of the mass to a point higher than it would be under a forced equality of distribution of wealth, the envies caused by disparity notwithstanding. The purely material standard in Great Britain was raised fourfold during the nineteenth century, and probably rather more in the United States. If we take into account also length of life and proportion of leisure, the increase is much greater. The improvement arises only to a very small extent in changes in the average innate capacity of man, not co-operant with, or parasitic upon, his environment. It is almost all due to innovation in social activity (including social education and the reactions of economic betterment upon physical and mental ability). The greater part of the innovation is scientific innovation—in physics, engineering, and public health—but a not inconsiderable part falls outside these categories, and belongs to the non-physical section—better ideas about money, more social confidence in banking and credit, improved political and social security, and legal frameworks for the better production and diffusion of wealth. The elaboration of these factors depends partly on intellectual prevision and invention, but mainly upon average moral standards, and calibre of character, since many political schemes, including international co-operation, are impracticable only because of failings in the present standards of human nature.

It is being commonly stated that scientific changes are coming so think and fast, or are so radical in their nature and implications, that the other factors of social life, the intangibles of credit, the improvements in political and international organisations and ideas, are unequal to the task of absorbing and accommodating them, or else they present new problems which have no counterpart. If changes in social forms and human nature or behaviour cannot possibly be made rapidly enough for the task, then in that sense science may " ruin " economic progress, and the world might be better served in the end if scientific innovation were retarded to the maximum rate of social and economic change.

Civilisation went through a long period when the limiting factor to progress was the scientific, but is now passing through a stage when the limiting factors are non-scientific. The lack of identity in the *tempo* of change creates new problems, tending to offset scientific advantages, of three types. First, for example, the utilisation for essential or competitive purposes of rare minerals, the need for which becomes general, but the distribution of which is particular and accidental, sets up great political strains, and we have invented no means of adjusted the international effects of accidental monopoly of essential elements. Secondly, the problem of scope, where the scale of production upon which, for example, a chemical innovation can be made to give its real economic advantages, is a scale inconsistent with the size of markets freely open in a nationalistic world. Here strains are set up in the international machine and the balance of trade, which may gravely jeopardise economic progress and dry up the juices of commerce. Thirdly, for example, where the innovation is absorbed most easily for offensive purposes in a military or naval sense, it may create rivalries and changes of balance of power inimical to economic security, and compel new economic sacrifices outweighing the direct economic advantages of peaceful uses. It is open to question whether the innovation of aircraft has yet become, on net balance, economic progress.

Inasmuch as all economic production creates real vested interest in a location or a skill devoted to it, and every scientific innovation alters the centre of gravity of collective demand, every such scientific change disturbs an economic equation. That equation for human life may often be richer ultimately, but the pain or waste of disturbance has to be debited to the gain, before the net balance is progress. For the time being, the balance may be net loss, the price paid for to-morrow. If to-morrow is continually postponed, because it, in its turn, is re-disturbed, and the economic to-morrow never comes, it is " jam yesterday, jam to-morrow, but never jam to-day." Wastes of absorption will be at a minimum in certain conditions, which are related to the wearing life of existing assets and places, and to the rate of flow of new skill into new directions.

The orderly absorption of innovation into economic process, apart from improvements in the non-economic factors of such progress, depends upon two kinds of balance. The first is the balance between two classes of scientific discovery, that which accelerates or makes easier the production of existing economic goods, and that which creates new kinds of economic satisfactions—the derivative and the direct. Let us suppose that in a static society a million people are employed making boots, and the gramophone has not been invented. Then let a labour-saving device be invented, such that the same quantity of boots can be made by half the workers, and boots are half the price. Assuming that the demand for boots is quite inelastic, and no more are wanted, there is potential unemployment for half a million people, and the whole population has now reserve unspent purchasing power, saved on cheaper boots. The gramophone is introduced, employing the potentially unemployed, and absorbing the reserve or released purchasing power.

The progress of the past hundred years has been essentially of this order, and innovation has enabled purchasing power to be released for new spending, first upon far *more* of the same article at the reduced price ; secondly, upon more of other existing goods ; and, thirdly, upon entirely new kinds of satisfaction, such as bicycles or radio sets. In this connection it must be remembered that an old article may be so transformed in degree as to be equivalent to a change in kind—the silk stocking and feminine footwear are cases in point. Now even if these two classes of innovation, direct and derivative, are in balance, the process of absorbing them will give rise to economic " growing pains " and temporary dislocations of capital and employment, but the gains will rapidly outweigh the disadvantages. But when they are not in balance, the process is more painful, and the debit to be set against progress very much greater.

The introduction of machinery has been for three hundred years accompanied by the same hostile arguments, for the immediate effects in unemployment are much more obvious and human than the countervailing employment given by the released purchasing power, which may occur in some other place or country. Illustrations may be found all the way from Queen Elizabeth's sentiments on stocking-knitting machinery to the Luddite riots, and the eight looms per weaver of to-day. But in the literature of the whole series, nothing can outdo, for detailed economic jeremiad and precise calculation of woe, a contemporary examination of the effect of the introduction of the stage coach in the middle of the seventeenth century upon the post horse industry and all that depended upon it (" In Grand Concern of England," 1673).

The argument so far, no doubt, begs the question of the meaning of progress, and assumes that silk stockings and fine shoes represent a " higher " standard of life than black, homespun woollens and rough boots—a doctrine that is not acceptable to Mr. De Valera, for example—but as we are not entering the field of morals or ethical aims, we are obliged to assume that those objects which are actually the subject of average human desire must be given their economic significance accordingly, and not attempt to solve the larger problem simultaneously. In this sense such a mechanical invention as the totalisator must take its place in " progress " at this stage.

The problem of balance, in the direct and the derivative, is not, however, so simple in practice, for the sum total of the effect of derivative innovation (creating technological unemployment) ought to be balanced by the sum total of direct innovations or increased demand for other products (new and expanded employment). But many direct innovations are not additive ; they are substitutional, and destroy the need for old commodities. If combs are made from celluloid and dishes from *papier mache* or pyrex, they will certainly not create a wholly additional demand or employment—there will be a displacement of the old types in metal or bone combs or china dishes. This substitution goes into rival classes of utility also, and a radio set may be a real substitute for a billiard table, and oil may be the enemy of hops, if cheap bus-riding supplants long sittings in public houses. These substitutions may be gradual enough to be absorbed as a normal feature of progress, but if they are very rapid and coincide with certain other economic disturbances, they may be very distressing. By " normal " I mean such as can be coped with by the direction of new labour entering industry or new capital spent on renewals, leaving the contractions to take place by natural age attrition without unemployment or by premature obsolescence—for the moment, this is the optimum point of change.

The lack of balance between derivative and direct innovation may be due, of course, to a terrific drive and rapidity in scientific recovery of the industrial type, but it is only fair to say that the excess of one may be due to causes on the economic side. If for purely monetary reasons, the gold standard, &c., the purchasing power of money is continually increasing through falling prices, and, with the current inability to change the money totals of wages and other costs, real wages are rising, it becomes increasingly possible to substitute innovations of machinery for hand labour or complex for simple. A change that was not worth making on a balance of old wage costs against new capital costs in 1923, became well worth making by 1932, and indeed imperative, if any profits were to be preserved. Hence the almost artificial pressure which a rigid monetary system may bring to bear towards the over-rapid application of new methods and creation of unemployment.

The second kind of balance which is vital to economic progress and may be ruined by over-rapid innovation is that between obsolescence and depreciation. Nearly all scientific advance for economic progress has to be embodied in capital forms, to be effective, more and more elaborate, large and costly. The productivity of such apparatus and plant per man involved becomes greater, and even allowing for the men employed in making the machinery or process, the total satisfaction is continually produced with less and less human effort. Now it used to be said of British machinery that it was made good enough to last for ever, and long after it became old fashioned, whereas American machines were made to be worn out much earlier, and were thus cheaper, but could be immediately replaced by capital assets containing the latest devices. If the period of physical life and fashionable life can be made to correspond, there is greatest economy and security of capital. But if the expensive embodiment of the latest science can be outmoded and superseded long before it is worn out, there is waste of capital, loss of interest, and resultant insecurity of business and investment.

The factor of physical safety alone means that each embodiment must be really durable, even if roughly finished, and therefore it is impossible wholly to reduce physical life to probable " obsolescent " life. In this way an over-rapid series of innovations may mean the scrapping or unprofitability of much excellent capital for very small marginal gains. A responsible socialist community would see each time that the gain was worth while, but competitive individuals have no collective responsibility. Suppose the giant Cunarder attracts a profitable contingent for two years only, when a lucky invention in a new and rival vessel attracts all her passengers at a slightly lower fare. Here is progress in one typical sense, but the small net advantage to be secured by individuals as free-lance *consumers* may be dearly purchased by large dislocations or loss of capital reacting even upon those same individuals as *producers*. Now, if the innovation were very striking, and were reflected in working costs, the margin of difference between the old working costs and new working costs may be large enough to pay interest on the new capital employed and also to amortise the cost of the unrealised life of the asset displaced. A locomotive may have many years of useful life left, but a new type *may* provide a margin by lower working costs not only sufficient to make one adopt it on normal renewal, but also to pay for the premature scrapping of the old type.

The majority of modern innovation is, however, of the type which does *not* pay the costs of obsolescence and proceed by orderly and natural physical renewal or substitution. A similar type of argument applies to the capital expenditure generally on a district, which can be amortised over the economic activity of that area, such as a colliery area, but which is wasted if a dislocation occurs by the adoption of some innovation stimulating rival activity in another place. Similar but more poignant considerations apply to obsolescence in human skill and training, more rapid than the ordinary attrition through age retirement can accommodate. Physical capital forms, human vocational training, and centring in geographical areas, are all essential features in the absorption of scientific innovation into economic progress. Each has its *natural* time span, and a narrower span of scientific change is bound to set up large economic debits to be set against the economic credits of the change. A man running a race might be stopped to be given a new magic cordial which, *after* allowing for the two minutes stoppage, would enable him to finish a minute earlier. But if he is stopped at frequent intervals for other magic cordials, each advantageous by itself, the total period of stoppages would at some point exceed the possible gains of speed during the short undisturbed running periods, and he would finish later at the post, instead of earlier. This is a parallel to the current effects of too rapid disturbance on progress.

Under an individualistic form of society, it is difficult to alter the social technique of change, and to make its credits really pay for the debits, and make all the people who gain by the profits on new capital pay also for the losses on prematurely displaced capital, or the gainers by cheapness and variety pay the human costs of unemployment and the skill no longer wanted. The *basic* economic reason for social unemployment relief is not the humanitarian argument of social obligation against distress, *or* the argument against revolution, but the plain argument that the gainers by innovation should bear the losses of innovation.

At the same time, much can be done to shorten the hitherto natural time span and make society ready to absorb the quickened tempo of science. No prices ought to be charged except on the basis of costs fully loaded with short-period obsolescence—this would prevent over-rapid substitution, economic only to a narrow range of people. We have no adequate technique of change ; we treat life as mainly static, with occasional and exceptional periods of change, whereas we must learn to look upon it as continuously changing, with occasional and abnormal periods of rest, and we have to secure all the changes of social outlook implied by that reversal of view.

The next field in which scientific advance alters the economic problem faster than we can solve it is in the duration of human life. We have to provide a social dividend adequate to maintain a much larger proportion beyond the age to contribute to it. Combined with the altered birth-rate, a profound change is taking place in age densities, and the turnover from an increasing to a stationary, and then a declining population, in sight in Great Britain, Belgium, Germany, and even the United States, is bound to affect the *tempo* of economic life. A larger and more immediate problem of adjustment is, of course, the absorption of the results of science not in increased masses of new kinds of commodities made by the released labour of labour-saving devices on old kinds, but in generalised leisure. The transition from a state of affairs in which we have an uneconomically high commodity wage paid to a part of the population, and the rest with a mere pittance and enforced idleness, to a state where a part of the reward is taken *all round* in larger leisure, and where economic satisfaction from leisure is deliberately equated to that from commodities in the standard of life, may need a surgical operation or a catalyst, such as the United States experiment can show.

In the past, the absorption of innovation has been achieved, according to contemporary explanation, by four agencies :—(1) Great elasticity of demand for the old commodities at reduced prices, food and staple household necessities ; (2) rapid introduction of new things ; (3) the rise in population *created* by the increase in produce ; (4) overseas outlets in more backward industrial countries. In the first the elasticity completely alters as the standard rises, and generally there is not now the scope for lower price in food or clothing increasing the demand *pro tanto* ; for the third, a rising standard no longer stimulates population but tends the opposite way ; for the fourth, the external outlets are now largely self-producers. As regards the rapid introduction of new things—those mostly now demand increased leisure for their proper absorption and use, so that the two are corelated and mutually dependent.

It can be conceived that a socialistic organisation of society could obviate such of the maladjustments as depend upon gains and risks of absorption not being in the same hands, and a theoretical technique can be worked out for the most profitable rate of absorption of scientific invention, having regard to invested capital, and skill and local interests. It is sufficient to say that it needs a *tour de force* of assumptions to make it function without hopelessly impairing that central feature of economic progress, namely, individual choice of the consumer in the direction of his demands, and an equally exalted view of the perfectibility of social organisation and political wisdom. But in the field of international relations and foreign trade, which alone can give full effect to scientific discovery, it demands qualities far beyond anything yet attainable.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

Import and Export Figures.

The Board of Trade returns of imports and exports for August provide some interesting figures. The imports of forge and foundry pig iron totalled 5350 tons, which was about 1200 tons more than in August last year. The imports of basic iron reached 9000 tons, and it is interesting to note that, whilst the total imports were 14,350 tons, 13,140 tons was provided by British India, and of the remainder 1180 tons came from Sweden. The exports of pig iron were 9093 tons in August, Italy being the largest consumer, with 1952 tons, whilst France took 1363 tons and Germany 1141 tons. For the eight months ended August 31st the total imports of pig iron were 63,649 tons, whilst the exports were 67,533 tons. Considerable interest attaches to the figures relating to imports of semi-finished steel. In August 20,085 tons of blooms, billets, and slabs were imported, compared with 28,464 tons in August, 1932. Of the quantities sent in last month, 10,512 came from Belgium, 5206 tons from France, and 4052 tons from Germany. In August, 1931, before the duties were imposed, the total was 32,905 tons. The total for the first eight months of this year reached the impressive figure of 138,909 tons, but this is relatively small compared with 266,675 tons for the similar period in 1932 and 305,705 tons in 1931. The imports of sheet bars and tin-plate bars last August were 4168 tons, compared with 19,949 tons a year ago. The figures for the period January–August of this year, when compared with previous years, give a good idea of the effect of the duties upon the importation of this class of material. In the eight months ending August 31st, 1931, the imports were 409,804 tons; in 1932 they were 318,677 tons, but this year they dropped to 48,878 tons. In the case of finished steel materials the import figures for a number of descriptions remain fairly steady. For instance, in August 4996 tons of girders, beams, and joists were imported, compared with 4378 tons in August, 1932, whilst for the first eight months of this year the total was 39,540 tons, compared with 35,448 tons for the similar period in 1932. Export trade in iron and steel was fairly satisfactory last month. The movement of galvanised sheets was especially encouraging, the total being 23,985 tons, compared with 20,153 tons in July, the figures of August last year being 19,121 tons. An improvement is also to be noted in the export of plates, which reached 11,601 tons in August, the total for the eight months being 87,222 tons, compared with 77,573 tons for the first eight months of 1932.

The Continental Position.

Although meetings of the European Steel Cartel were held last week, no announcement, either regarding policy or the position of the steel works, has been made. It is known, however, that the situation has deteriorated sufficiently to cause anxiety. In Belgium practically all the works are compelled to close departments at frequent intervals from lack of orders, and the French home demand, which for some time past has been the mainstay of the French steel industry, now shows signs of declining. The Cartel, however, has maintained its gold quotations, and the rate of exchange which existed most of last week and the beginning of this week has enabled it to compete for business in the British home market at figures well under the quotations of the British manufacturers. That they have taken comparatively little business is largely due to the fact that many of the British consumers have running contracts with British works. Another factor in the situation is that the exchange fluctuates so rapidly these days that buyers adopt a cautious policy in dealing with countries upon the gold standard. The movements of the dollar this week have, of course, disturbed all markets, and there has been a certain amount of American competition. Sales of the lighter steel materials have been made to buyers in this country and on the Continent, and it is reported that some American tin-plates have been sold in Germany. On the whole, however, the competition experienced from the United States is not so serious as might have been anticipated. There seems to be, however, a general feeling that if the dollar deteriorates further American rivalry may become a grave menace to other steel-producing countries.

Pig Iron Production.

THE National Federation of Iron and Steel Manufacturers, in the preface to its figures of iron and steel production for August, states that there were seventy-three furnaces in full blast at the end of the month, the four furnaces which had been damped down at the end of July having resumed operations, and two other furnaces which were put into blast being offset by two which ceased production during August. Although it is not stated in the report, of the two furnaces put into commission, one was at the works of Walter Scott, Ltd., Leeds, and one at David Colville and Sons, Ltd., whilst one furnace at the Millom and Askham Hematite Iron Company, Ltd., and another at G. and R. Thomas, Ltd., in the Midlands, ceased production. The output of pig iron in August amounted to 362,700 tons, compared with 343,900 tons in July and 259,400 tons in August, 1932. The production includes 104,300 tons of hematite, 168,700 tons of basic, 74,100 tons of foundry, and 7800 tons of forge pig iron. The output of steel ingots and castings in August was affected by the holidays, and amounted to 551,300 tons, as against 567,500 tons in July and 361,500 tons in August, 1932.

Pig Iron.

Business in pig iron has been on a satisfactory scale for some time and a further expansion is looked for during the present quarter. Active conditions are reported on the North-East Coast, and not only are local consumers taking increased quantities, but overseas business has improved. One of the most encouraging features is that Denmark has taken about 3000 tons. The demand for hematite also has increased, business having been done on a good scale with Sheffield and South Wales consumers. Hopes are entertained that production will be increased shortly. Already one furnace has been started up this month, and it is expected that one or two more will be relighted in the near future. The demand for Cleveland iron from Scotland looks like increasing at the current figures of 65s. 3d. d/d Glasgow and 62s. 3d. d/d Falkirk. In the Midlands also the situation is satisfactory, and business has expanded since the beginning of the month, although many of the large consumers have covered their forward requirements, and the demand at the moment consists chiefly of small parcels to meet current needs. The light castings foundries are the principal buyers and are busily employed, particularly those supplying the building trades. An encouraging feature is the better demand for forge iron, which is quoted at 61s. for Derbyshire brands and 57s. 6d. for Northamptonshire. In Lancashire the demand for pig iron does not seem to be so good, but this is probably because consumers there covered their requirements a short time ago, many of them buying well forward. Specifications against these contracts are coming forward satisfactorily. For the time being the demand is light, but one of the favourable features of the position is the tendency for scrap prices to rise, which should be a factor in improving the demand for pig iron. On the North-West Coast business in hematite has been maintained. Buying has been of a hand-to-mouth character, but the makers have good orders on their books, against which consumers are specifying with fair regularity. The local consumption is good and a considerable amount of iron is going to the Midlands and South Wales. The position of the Scottish producers has not altered much recently. Business in foundry iron is light, but it is expected that the output of basic will be increased shortly.

Semi-finished Steel.

The volume of business in semi-finished steel has become somewhat irregular. In one or two districts little business has been transacted of late, but this is probably due to the fact that many consumers have covered their requirements well into the fourth quarter. From the manufacturers' point of view the position is so satisfactory that many of them have been encouraged to ask prices higher than the official quotations. For instance, billets, which until recently have been booked at £5 for 500-ton lots and £5 7s. 6d. for lots of 100 tons or less, are now difficult to obtain at less than £5 2s. 6d. to £5 5s., unless the tonnage is particularly attractive. In Lancashire, where the demand is distinctly quiet, it is possible that the makers would be more willing to meet consumers, but in the Midlands up to £5 5s. and £5 10s. has been quoted, the higher figure being for small quantities. Similarly, the quotation for sheet bars has advanced, probably as a result of the busier conditions which have developed in the black and galvanised sheet branch of the industry. The price of £4 15s. which has ruled for some time on the North-East Coast, has been advanced by most makers to £4 17s. 6d. to £5, and this position seems to be gradually spreading to other districts in England. In Wales, however, sheet and tin-plate bars are kept at the official figure of £4 15s. d/d. In spite of the advance in prices, Continental competition is seldom met with in the home market. The sales organisations of the Continental works are prepared to discuss terms irrespective of the official prices, which, when the depreciated exchange and the duty are taken into account, are nearly as high as the British quotations. It is only occasionally, however, that Continental works press large offerings on the British market, since they are not attracted by the prices they must accept. British import merchants who are excluded by the Continental works from participating in any business in semi-finished material have adopted a strong attitude, and negotiations have been opened with the Continental makers which may result in the situation being altered.

N.E. Coast, the Midlands, and South Wales.

Conditions in the manufactured steel department have not materially changed over the week, but there is evidence of a steady, if slow, expansion in business. In a few departments there is considerable activity, and some works are booked up for several weeks ahead. The galvanised sheet section of the market, for instance, which until recently was probably more depressed than any other, is now well employed as a result of recent orders, and several makers have temporarily withdrawn from the market. The tin-plate works have been operating at between 65 and 70 per cent. of capacity for several months and constructional engineers, generally speaking, have found business improving of late, although conditions in this industry are irregular. The demand for strip, hoops, and steel bars is a feature of the market, and some of the English re-rollers are working at a high rate. On the North-East Coast the active conditions that have ruled for the past two or three months are well maintained. In this district the constructional engineers are supplying the steel works with a fair amount of work. The rail mills also are well employed. The demand for shipbuilding steel, however, remains poor. In the Midlands general business in finished steel is improving and orders for bars, joists, and sections are reaching the mills more freely than for some time past. The re-rollers are well off for work, but this week there has been a revival of competition from the Continent, chiefly in small steel bars. The Continental quotation has dropped to £6 9s. delivered Birmingham, against the re-rollers' quotation of £6 15s. to £6 17s. 6d., to which it was recently raised. The English steel makers quote £7 to £8. Although some orders have gone to the Continent, they appear to have been confined to small tonnages. Some disappointment is felt in the Midlands that the usual seasonal demand from the collieries for arches, rails, and other material does not materialise. Reports from South Wales indicate that business has been quiet of late, but most of the works have well-filled order books.

Scotland and the North.

One of the most encouraging features in the position of the Scottish steel industry is the busy conditions at the Clydebridge Works of David Colville, Ltd. The three shift system is in operation on the plate mill and for the first time for years the mill has been working night and day. There is only a sluggish demand for structural material and most of the orders received are for small tonnages; but even in this department production is maintained at a higher rate than ruled last year. Business in tubes, also, has increased recently and the Mossend Works of Stewarts and Lloyds, Ltd., are working full time. The Scottish re-rollers do not appear to be so well off for work as their English competitors and in particular are finding export business difficult to secure. Disappointment continues to be felt in Lancashire at the slow development of the demand from the general engineering firms. Earlier in the year a short-lived improvement in the position of this industry encouraged hopes that have not been realised. On the other hand, the constructional engineers appear busier and are taking better deliveries of joists and sections. Business in plates has been confined this week to a few small transactions, and the call for boiler plates does not seem likely to improve as the boilermakers are poorly employed. There is a good business passing in bright-drawn bars and in some of the special steels. In the Sheffield district the volume of business appears to be steadily improving. One authority places the production of steel there at 1000 tons per day higher than at this time last year. The gradual growth of the demand for special steels is an encouraging feature, and a large export order for tool steel has been secured and will be divided between several firms. The wire rod mills have a considerable number of orders on their books and the demand for stainless steel sheets is on a satisfactory scale. Business in hot and cold-rolled strip, which has been active for some time, has, if anything, increased of late. On the North-West Coast the steel works have found new orders scarce, but there is sufficient work in hand to keep them employed for a considerable time.

American and British Capital.

One of the consequences of the American slump and the readjustment which it caused in many businesses on the other side of the Atlantic has been that interests held by American concerns in this country have been disposed of in a number of cases. It is only natural that the tendency should be for firms to concentrate upon the markets with which they are best acquainted, and this often provides a reason for the severance of foreign financial relations. During the past year or so a number of instances have occurred in which American holdings in British companies have been transferred to British interests, and in some cases also a reverse action has taken place. Various reasons are responsible besides those mentioned for this development, but, generally speaking, such considerations have carried weight. A dissolution of British and American interests which is of considerable interest is understood to have just taken place. Negotiations which have been proceeding for some time have now been completed, and the shares held by the International Combustion Engineering Corporation of New York in International Combustion, Ltd., of Aldwych House, Aldwych, London, W.C.2, have been acquired by English interests. No shares are now held in the United States.

Copper and Tin.

The slight burst of activity that occurred in the electrolytic copper market at the end of last week was short-lived, and this week the market seemed to have dropped back into a listless condition. American consumers bought a little more freely and business in Europe, although it has been irregular, has been on a slightly improved scale. There is no doubt that the buying was caused by rumours of American monetary inflation, and it is probable that in the United States a certain amount of copper was bought as an investment. The American domestic price has been held at 9 cents, and apparently there has been little or no selling by second-hands to disturb the market. The sterling quotation has moved between £38 5s. and £38 15s. c.i.f. British consumers have not shown much interest in the market, and the principal export buying has been from Germany, and to some extent from France. Some transactions are reported to have been entered into for delivery up to the first quarter of next year, but the quantities involved were not large. Estimates of the American copper position at the end of August give a reduction of 23,500 tons in the stocks. The stocks in the American producers' hands, however, are still heavy enough to be a burden to the market. Business in the London standard market reflected the activity of electrolytic copper, but this week an easier tone developed. Prices have moved within a narrow margin, and for the time being speculators are showing little interest in this market. . . . The American situation also influenced the tin market, but expectations that American buying would revive on a considerable scale as a result of the threat of inflation have not been realised. A certain amount of buying took place at the end of last week, but not enough to influence prices seriously, whilst the Continent has shown little interest in the market. The statistical position of the metal continues to improve, and last week there was a very heavy reduction in the stocks of the United Kingdom owing to large shipments of tin to the United States. The International Tin Pool met this week, but although it had been suggested that the production quota would be increased, no announcement followed the meeting. This has confirmed the belief of the market that no change will be made until January. The uncertainty, however, on this point has no doubt done something to check speculation in the metal.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers : joists, 22s. 6d. ; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

Foreign Exchanges and Quotas.

As stated in a previous note the Government has decided to suppress three-quarters of the import quotas based upon the percentages of particular goods received from each country during a specified period, and to make use of those quotas as a means of exchange during negotiations for new treaty arrangements. A first list of goods to be freed from quotas has just been published. For the moment, the only engineering productions released from the quota system are traction engines and road rollers, steam boilers and transmission systems, while cutlery and steel furniture are also included in the list. At the same time, the Cabinet has met to discuss the policy to be adopted in order to facilitate foreign trade. This matter has become extremely urgent in view of the rapid decline of exchanges, particularly the exports of manufactured goods, and the reorganisation of the foreign trade is to be carried on simultaneously with reforms that must be undertaken to avoid serious risk to the country's financial stability. One of these reforms cannot be accomplished successfully without the other. Negotiations have long been in progress with several countries, and have been held up because there has been no means of settling upon an acceptable system of exchanges, but with the partial removal of the *pro rata* system the Government believes that it has now the means of offering advantages which will allow of negotiations being carried through satisfactorily. The first step has been to apply a quota to imports of dairy produce from the Irish Free State in return for certain French products. Another reason for an urgent solution of the difficulties that stand in the way of foreign exchanges lies in the arrangements being made between other countries which may have the effect of excluding French interests altogether, such as the agreement between Germany and Rumania, whereby the latter country undertakes to purchase German goods in return for an equivalent value in cereals. This releasing of quotas for the purpose of exchange may also allow of negotiations being resumed with Great Britain. They were initiated by French Ministers in London during the World Economic Conference. On their return it was announced that the Government contemplated the suppression of the compensating duty on British goods; but in view of protests from industrial interests the suggestion has apparently been allowed to drop. The compensating tax has not been imposed on goods from the United States, despite the fact that the dollar has depreciated to the same extent as sterling.

The Port of Dunkirk.

The changed economic conditions in the North of France after the war, when the reconstruction practically doubled the industrial capacity and the retrocession of Alsace-Loraine brought a new volume of traffic within the French transport system, induced the Dunkirk Chamber of Commerce to carry out works for an extension and equipment of the port in order to divert to it the traffic that was being sent by way of the Rhine and other waterways to Rotterdam and Antwerp. It was also believed that Dunkirk would become a convenient port of transit for cereals to Central Europe, for which purpose a vast grain elevator has been constructed. The success of the scheme depends upon an improvement of the canal system across the North of France, and this is being accomplished by deepening and widening the canals and creating an inland port at Lille. The programme of works at Dunkirk is being continued by the construction of an outer port which will have an area of 200 acres. It is enclosed by two piers converging to a point and providing an opening of 270 m. The eastern pier is an extension of an existing jetty and is built up with reinforced concrete piles on concrete foundations 17 m. by 7 m. The piles have a height of 7 m. and are placed 3·5 m. apart. They are precast, and are placed in position with a portal crane on a temporary metallic staging. The western pier serves as a breakwater, and is made of concrete blocks weighing 50 tons laid on a rock foundation. The outer port is being put into communication with the canals by means of a lock 280 m. long and 40 m. wide. The terminals of the canals themselves have also necessitated a considerable amount of work.

An African Tunnel.

The driving of the tunnel 1609 m. long through the Bamba mountain for the Congo-Ocean railway was completed last week, when the galleries from each end joined with a difference in level of less than 4in. All the work on the line between Brazzaville and Pointe-Noire has been extremely arduous, partly over marshes and through jungles where malaria exacted a heavy toll on labour, and the difficulties were no less serious during the construction of the tunnel which had to be driven with great caution. Water and mud constantly invaded the workings. The Bamba tunnel removes the last obstacle to the construction of the line, and work can now be continued normally with a prospect of the railway being put into service in March next. For several months past it has been used for transport by transferring passengers from one completed section to the other by means of motor cars. Unfortunately, the engineer in charge, Monsieur Girard, of the Société de Construction des Batignolles, lost his life in an accident on the line. Nearly the whole of his career had been devoted to colonial railway construction.

The Bargemen's Strike.

The recent bargemen's strike terminated on the Minister of Public Works promising to put into effect certain changes in the regulations governing traffic on the canals, notably the suppression of priority to motor boats passing through locks, the object of this measure being to deprive motor barges of any preference over electrically hauled boats. The strike was resumed last week on the ground that the new rule was not being observed, and that permits to barges carrying perishable goods were given to others not entitled to them. This uncompromising attitude of the bargemen is making it more than ever difficult to conciliate the interests of electrical haulage and oil-engine traction.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office, Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

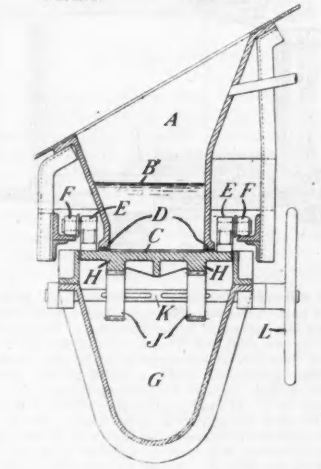
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

STEAM GENERATORS.

396,767. February 5th, 1932.—REMOVAL OF ASH FROM FURNACES, The Underfeed Stoker Company, Ltd., of Aldwych House, Aldwych, London, W.C.2, and Howard Kerr, of 37, Oak-avenue, Shirley, Surrey.

According to this invention a hopper or receptacle, placed at the rear of a boiler stoker, is adapted to contain water and is provided with a displaceable bottom normally making water-tight connection with the hopper walls, whereby its contents may be discharged into a sluicing channel or other conveying device. The ash being more or less quenched on falling into this water-filled hopper has no adhesive tendency, so that clinker is not formed. Provision may be made for automatically or otherwise making good any water evaporated from the hopper by the heat of the ash. A is a hopper the mouth of which is situated beyond and below the rear end of the stoker, which may be of any suitable type. The ash from the stoker falls either directly or through a chute into the hopper A containing water. When the hopper A contains no ash, the water stands at a level B, so that when the hopper is filled with ash it will rise to the top of the hopper, or to an overflow lip or discharge aperture leading to a sump or other receptacle. The hopper A has a movable closure or bottom C between which and the walls of the hopper a water-tight or approximately water-tight joint is maintained by sealing strips or gaskets D accommodated in grooves. The bottom C of the hopper is bolted to brackets E, in which the axles of bearing rollers F are journalled. Below the hopper A is a sluicing channel G or other receptacle into which the contents of the hopper are discharged for removal by any suitable means when the bottom C of the hopper is displaced laterally with respect to the body portion of the hopper. This movement of the bottom may be effected by means of a rack or racks H actuated by pinions J keyed on a transverse shaft K journalled in the framework and rotatable in its bearings as by means of a hand wheel L.—*August 8th*, 1933.

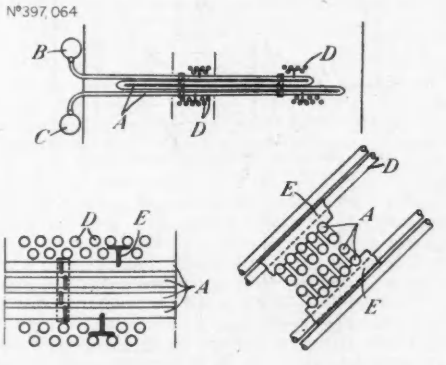
N°396,767



397,064. March 30th, 1933.—SUPERHEATER ELEMENTS IN WATER TUBE BOILERS, *The Superheater Company, Ltd., of Bush House, Aldwych, London, W.C.2.*

The object of this present invention is to provide a simple and efficient means for positioning and supporting the superheater elements in a water tube boiler. A indicates a superheater element comprising four branches or pipe lengths arranged side by side in a common plane, and B and C indicate the saturated steam and superheater steam headers respectively. The elements of the superheater are arranged in a space between rows or banks of water tubes D. Secured to water tubes at opposite sides of the space in which the superheater elements are accommodated are supporting members E, which are formed of lengths of "T" iron, the flanges of the "T" iron being welded to two of the water tubes, the web having spaced semi-circular notches or recesses to receive the outer legs or branches of the superheater elements. In the example shown, the recessed members E are welded to water tubes in the row next to the row adjacent to the superheater elements, the flanges of the "T" iron being welded to the sides of the water tubes facing the superheater elements.—*August 17th*, 1933.

N°397,064

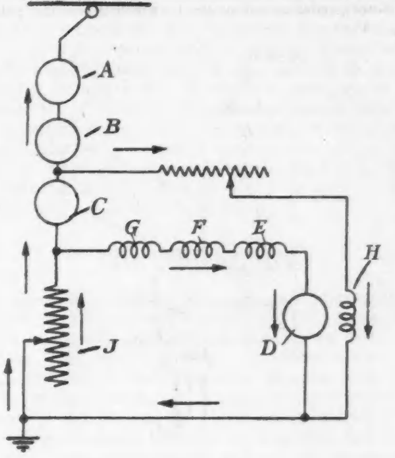


DYNAMOS AND MOTORS.

396,410. February 2nd, 1932.—CONTROL OF DIRECT-CURRENT ELECTRIC MOTORS, Frank Whyman, of "Arncott," Greenway-road, Timperley, Chester; and Associated Electrical Industries, Ltd., of Crown House, Aldwych, W.C.2.

In systems of electric motor control wherein provision is made for electric propelling motors to work regeneratively it has been proposed to utilise one of the propelling motors when working regeneratively to supply excitation current for the other motors, and the present invention provides new arrangements of this kind. The armatures of the four motors are indicated at A, B, C, D and their respective field windings at E, F, G, H. The connections shown are when the motors A, B C are regenerating for the purpose of returning current to the line. The armatures of these motors are connected in series with a stabilising resistance J between the supply conductor and earth. The field windings E, F, G of the three motors are connected in series with the armature D of the fourth or exciting motor across the stabilising resistance J. Two alternative methods of carrying out the invention are described.—*August 2nd*, 1933.

N°396,410

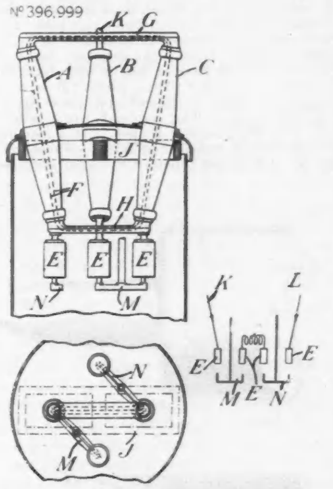


SWITCHGEAR.

396,999. December 16th, 1932.—LIQUID BREAK ELECTRIC CIRCUIT BREAKERS, *International General Electric Company, Incorporated, of 120, Broadway, New York, U.S.A.*

On the cover of the series-multiple break liquid circuit breaker, described in this specification, there are four bushings, of which only three, A, B, C, are shown, which carry the explosion chambers E. The bushings and explosion chambers are arranged symmetrically in a circle. Through the two diametrically opposite bushings A and C, the high-voltage-winding F of a current transformer is wound in several layers. Outside of the bushings it is conveyed in strong tubes G, H, which brace the ends of the bushings A and C. The two transformer bushings also pass through the windows of the core J, which carries the secondary winding of the transformer. Instead of a single core, a separate core can be provided for each of the bushings A and C. The bushing B and that diametrically opposite to it carry the conductor connections K, L. The two movable switch cross-bars M and N bridge adjacent explosion chamber contacts in the manner shown.—*August 17th*, 1933.

N°396,999

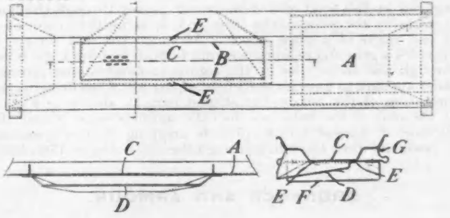


CRANES AND CONVEYORS.

396,602. December 10th, 1932.—CONVEYORS, The Fife Coal Company, Ltd., and John Paton, both of Leven, Fifeshire.

This invention is concerned with conveyors with a connected series of pans and although applicable to conveyors of the scraper type, is specially applicable to those of the jigging type. The conveyor shown includes a base A with a gap B accommodating a perforated plate C which serves as a screen. On the underside of the pan adjacent to the perforated plate C is a reversible chute D, which serves to convey coal dust, &c., to one side of the conveyor after passing through the perforated plate C. The chute D is secured to the tray by bolts, and when it is desired to reverse the chute it is removed from the tray and after it has been turned through 180 deg. it is again secured to the tray. The plate is joggled along its lateral edges so as to form flanges E adapted to be bolted to the base of the pan. F denotes a pair

N°396,602



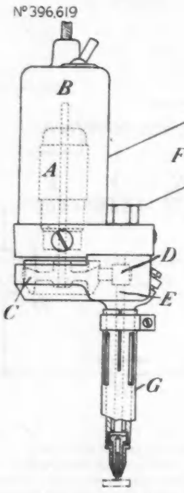
of flats bolted to the lugs G to shield the chute from contact with fixed objects below the pan.—*August 10th*, 1933.

MACHINE TOOLS AND SHOP APPLIANCES.

396,619. January 11th, 1933.—Portable Electric Grinding Machines, Robert Bosch Aktiengesellschaft, of 4, Militärstrasse, Stuttgart, Germany.

An electric motor A is arranged in the casing B. The shaft of the motor carries a belt pulley C, which drives the pulley D connected to the driving spindle E. The outstanding feature, however, is that in addition to the handle F an insulating sleeve is provided at G, and when exceptionally small objects have to be ground or when very exact grinding has to be done the tool is held by this sleeve instead of the handle F.—*August 10th*, 1933.

N°396,619



396,841. March 1st, 1932.—Mandrels for use in Making Metal Tubes, James Robert Garner, of Sheffield Tube Works, Alsing-road, Wincobank, Sheffield.

The mandrel described in this specification is for use in making metal tubes by the cupping or push bench process, in which a partially pierced heated billet is placed on the end of the mandrel and forced through a die, or, in the case of smaller tubes, through a succession of co-axially disposed dies. The object of the invention is to provide means for shaping the leading end of the tube during the push bench process in such manner that when the mandrel is withdrawn from the tube the latter is ready, with little or no further preparation, to be cold drawn into a smaller diameter tube. The mandrel comprises a cylindrical portion A of the desired length and diameter. At its operative end it is provided with a piercer B surrounded by a gripping region C, which operates to push and draw the billet through the die or dies. The piercer B projects from the flat end surface C of the mandrel proper, and a rounded edge or corner D is provided between the flat end surface and the cylindrical part A. A rounded junction E is also provided between the piercer B and the end surface C. The piercer is provided by a pointed stem which may be integral with the mandrel, or may be screwed, welded, or otherwise secured to it. Experiments have shown that a mandrel with the stem of its pointed piercer having a diameter approximately one-third that of the mandrel, may be successfully used in a push bench process of tube forming. The billet is pierced at the first die and it is found that the leading end of the tube F is cup-shaped, as shown in Fig. 2, when the mandrel is withdrawn, so that it may be engaged by the head of a stem or bolt passed through the hole G made by the piercer, the stem or bolt being then connected to the chain of a draw bench. Although the end surface C provides a gripping region operating to push and draw the billet through the die or dies at the commencement of the process, there appears to be a forward flow of the metal resulting in the formation of the hollow cup-shaped part H, shown in Fig. 2, at the end of the tube, so that the annular edge D and the shoulder E appear also to provide gripping regions operating to push and draw the billet through the die.—*August 17th*, 1933.

N°396.841

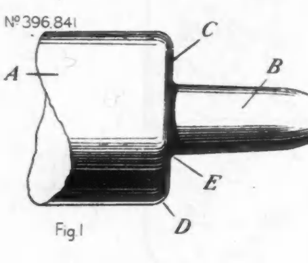


Fig. 1

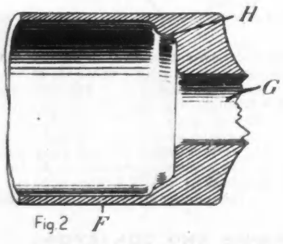

Fig. 2

ORDNANCE AND ARMOUR.

396,405. February 2nd, 1932.—Relatively Bullet-proof Sheet Materials or Moulded Compositions, *The British Thomson-Houston Company, Ltd., of Crown House, Aldwych, London, W.C.2.*

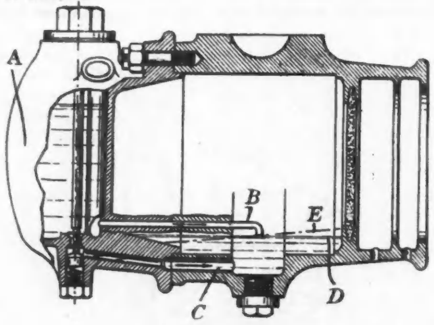
According to this invention, a moulded laminated bullet-proof material is formed of alternate sheet layers of fibrous material and of an abrasive such as finely powdered glass, quartz, sharp quality sand, or carborundum, the layers being bonded together with a resinous composition or a varnish which hardens under subsequent heat and pressure treatment. In carrying the invention into effect according to one form sheets of glass paper are impregnated with a synthetic resin, for example, of the phenolic-aldehyde type, or with a varnish containing synthetic resin, or one containing such bonding media as bitumen or albumen, the sheets being subjected to heat and pressure to cause bonding. The number of sheets bonded together depends on the required thickness of the finished board. It has been found that a comparatively thin board of material made in this way will effectively arrest a rifle or machine gun bullet.—*August 2nd*, 1933.

MISCELLANEOUS.

396,413. November 27th, 1931.—Boxes of Axle Bearings, Jules Edmond Joseph Leroy and Auguste Louis Marie Antoine Rouy, both of 17, Rue de la Bienfaisance, Paris, France.

The type of bearing to which this invention applies usually consists of two sets of needle bearings and also a thrust bearing preferably mounted between the two needle bearings, but the illustration does not show the bearings or shaft. The reservoir A is connected to the oil bath by two conduits B C, one of which starts at the base of the reservoir and ends below the surface of the oil in the bath, and the other starts at the top of the reservoir and ends substantially at the surface level of the oil in the oil bath, and at the line of intersection of the planes, which the surface level of the oil may assume for various lateral inclinations of the journal box. When the level of the oil in the chamber is lowered, air will enter through the conduit B and thus proceed to the upper part of the receptacle A. At the same time the oil flows through the passage C in the direction of the arrow. Thus the level of the oil rises and the oil soon closes the end of the passage B so that the air will cease to enter the upper part of the receptacle. Under the action of atmospheric pressure the oil will cease to flow through the passage C and the level will become steady at D. When the journal is exactly horizontal the surface of the oil in the axle-box is at D, but when the journal becomes inclined as occasioned, for instance, by an inclination of the track on curves, the surface of the oil bath will have the level shown by the line E. It will be observed that this line intersects the level line D and no air will enter and hence there will be no improper reduction in the supply of oil when the journal is inclined.—*July 29th*, 1933.

N°396,413



396,912. June 13th, 1932.—The Manufacture of Ice, Hugh Archibald John Macpherson, of 100, Logan-street, Glasgow.

According to this invention ice-making plant includes means whereby air from the ice tank, after being used for agitating the water in the mould boxes, is used as a cooling medium for the water to be frozen, and is then conducted back to the compressor for supplying the agitating air. Air from the ice tank A is conducted by a pipe to a tank C, and from this tank to the suction side of the air compressor D by a pipe E. The tank C is provided with a coil or coils of piping F connected to a water supply G, which may include a filter, and to the tank H from which the mould boxes are supplied. Alternatively, the coil or coils of piping F may be connected to the suction side of the compressor, and to the ice tank, and the tank C may be connected to the water supply and to the supply tank H, whereby the air flows through the coil or coils of piping F and the water to be frozen flows through the tank C. In connection with the alternative arrangement, the water in the tank C may be maintained in a state of motion by means of a jet of compressed air caused to enter the tank C through a small nozzle located in the bottom. A two-way cock may be incorporated in the pipe E, or in the pipe connecting A and C, so that, if desired, the connection between the compressor D and the tank A may be opened to the atmosphere should the temperature of the supply water to the tank H be reduced too much. Air from the compressor D may be conducted by the pipe J through the coil of piping K in the usual thawing tank L and the pipe M to the air cooler N containing brine O. The discharge end of the pipe M is located below the level of the liquid O. Cooled air from the space P above the liquid level is conducted to the ice mould boxes—not shown—by the pipe V. The freezing liquid R in the ice tank is circulated by means of the pump S and piping T through the coil of piping U, which is immersed in the liquid O.—*August 17th*, 1933.

Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the TIME *and* PLACE *at which the meeting is to be held should be clearly stated.*

To-day and Saturday, September 23rd.

Shipping, Engineering and Machinery Exhibition.—Olympia, London, W. Daily, 11 a.m. to 9 p.m.

Wednesday, September 27th.

Electrodepositors' Technical Society.—Lyons' Angel Café, Islington, N.1. Discussion, "The Removal of Electrodeposits by Stripping." Openers, Messrs. F. L. James and J. W. Perring. 7.30 p.m.

Institution of Welding Engineers: North-Western Branch.—Manchester College of Technology, Manchester. "Experiences by Practical Welders." Speakers, Messrs. W. Bellingham, W. W. Ely, C. Peat, and E. W. Hart. 7.30 p.m.

Thursday, September 28th.

Inst. of Locomotive Engineers.—At Inst. of Civil Engineers, Gt. George-street, S.W.1. Presidential Address, "Colonial Railways," Major Charles Williams, C.B.E. 6 p.m.

Saturday, September 30th.

Manchester Assoc. of Engineers.—Visit to works of Henry Simon, Ltd., Cheadle Heath. 2.15 p.m.

Tuesday, October 3rd.

Inst. of Engineers and Shipbuilders in Scotland.—Elmbank-crescent, Glasgow. Presidential Address, Professor J. D. Cormack.

Wednesday to Saturday, October 4th to October 14th.

Institute of Patentees.—Central Hall, Westminster, S.W.1. Ninth International Exhibition of Inventions. Daily.

Thursday, October 5th.

Stephenson Locomotive Society.—No. 1, Dining Club, King's Cross Station, N.1. "The Railways of South Wales," Mr. D. S. Barrie. 6.30 p.m.

Friday, October 6th.

Inst. of Chemical Engineers.—In Rooms of Chemical Soc., Burlington House, W.1. "The Sedimentation of Fine Particles in Liquids: A Survey of Theory and Practice," Mr. R. F. Stewart and Dr. E. J. Roberts. 6 p.m.

Institution of Sanitary Engineers.—Caxton House (Hill's Restaurant), Tothill-street, Westminster, S.W.1. Opening sessional meeting. Reception, 7.30 p.m.; music and dancing, 8 p.m. until 11.30 p.m.

Junior Inst. of Engineers.—39, Victoria-street, S.W.1. "Education with Particular Reference to the Engineer," Mr. K. W. Willans. 7.30 p.m.

Physical Society.—At Royal Institution, 21, Albemarle-street, W.1. Council meeting, 4 p.m.; extraordinary general meeting, 5.30 p.m. Thomas Young Oration, "Thomas Young and the Simplification of the Artist's Palette," Dr. Herbert E. Ives. 5.45 p.m.

Railway Club.—57, Fetter-lane, E.C.4. "Permanent Way," Mr. W. A. Willox. 7.30 p.m.

Thursday, October 12th.

Diesel Engine Users Assoc.—Joint meeting with Inst. of Chemical Engineers, Caxton Hall, S.W.1. "Treatment of Cooling Water for Diesel Engines," Mr. L. O. Newton. 3 p.m.

Royal Aeronautical Society.—At Royal Society of Arts, John-street, Adelphi, W.C.2. "Air Traffic Control," Major R. H. S. Mealing. 6.30 p.m.

Friday, October 13th.

Inst. of Engineers and Shipbuilders in Scotland.—Grosvenor Restaurant, Glasgow. "James Watt" dinner.

Junior Inst. of Engineers.—39, Victoria-street, S.W.1. "The Influence of Harmonics in Transformer Circuits," Mr. E. Ambrose. 7.30 p.m.

Friday, October 20th.

North-East Coast Institution of Engineers and Shipbuilders.—Bolbec Hall, Newcastle-upon-Tyne. Annual general meeting. Address by the President, Mr. R. J. Walker; cinematograph film, "Mechanism of Ships' Wake," Professor T. B. Abell.

Saturday, October 28th.

Stephenson Locomotive Society.—Visit to Stratford, L.N.E. Railway Running Sheds. 2.30 p.m.

PERSONAL AND BUSINESS ANNOUNCEMENTS.

The British Electrical and Allied Industries Research Association is removing to 15, Savoy-street, London, W.C.2., on September 28th. Telephone numbers will be Temple Bar 7907, 7908, and 7909.

Mr. A. S. Herbert, M.I.E.E., deputy export manager of the English Electric Company, Ltd., and for many years its general manager in Australia, has resigned his position from September 30th in order to join the firm of Herbert and Sons, Ltd., of 6 and 7, West Smithfield, E.C.1, with a seat on the board.

David Brown and Sons (Hudd.), Ltd., Huddersfield, inform us that their subsidiary company, the Keighley Gear Company, has found it necessary to move to larger premises. From September 18th, therefore, the entire plant and *personnel* will be transferred to Prospect Works, Lockwood, Huddersfield.

CONTRACTS.

Ferranti Ltd. have just received an order in the face of world-wide competition for the first large British-made transformer to be installed in Finland. It will be a three-phase unit of 12,000 kVA capacity for operation at 47,000 volts, with on-load tap-changing gear, and it will be used in connection with the transmission of power from the Imatra hydro-electric scheme to the Warkhaus paper pulp factories.

William Asquith, Ltd., Halifax, have received an order for a 48in. carriage and wagon wheel turning lathe for one of the leading Indian Railway Works, and another order from an Indian railway company is for an electrically driven S.C. 1 type radial drilling machine, whilst a locomotive wheel tire drilling and tapping machine is in hand for an Irish railway. Large electrically driven radial drills have also been ordered by a leading home railway company and by the Admiralty, whilst an important omnibus company has placed an order for a crank case boring machine.

A Seven-Day Journal

The Bogie Locomotive.

About this time in September, 1833, the bogie locomotive made its appearance on a British railway, although it was probably preceded by engines built earlier in the same year by Tayleur and Co.—now the Vulcan Foundry, Newton-le-Willows—and R. Stephenson and Co. Two engines were completed in March and April by Tayleur and exported to the Camden and Woodbury Railroad. They would now be described as 4–2–0's. The inside driving axle was under the footplate and the wheels were 4ft. 6in. in diameter. A similar engine was built by Stephensons for the Saratoga and Schenectady Railroad. The bogies were in front. The first British bogie locomotive was constructed by J. and C. Carmichael, of Dundee, for the Dundee and Newtyle Railway, now L.M.S., then on the 4ft. 6in. gauge. It, and its two sisters, had vertical cylinders, 11in. by 18in., placed on the running board just behind the single 5ft. drivers. The motion from the upwardly extending piston-rods was taken by return connecting-rods to large bell-crank levers, the vertical leg of which drove outside cranks by means of connecting-rods. The four-wheeled bogie was at the rear; its wheels were 3ft. in diameter. The boiler pressure was 50 lb. per square inch, the total weight in working order about 9½ tons, and the price £700 each. It is interesting to compare the tractive effort of 1530 lb. at 85 per cent. of the boiler pressure with the 40,300 lb. tractive effort of the "Princess Royal," the latest L.M.S. engine. One of these engines, the "Earl of Airlie," was at work as late as 1850, when it was converted into a pumping engine. Our knowledge of its appearance is due to Alexander Allan, who had it put in order and photographed. A woodcut from the photograph was given in The Engineer of March 2nd, 1883.

Zuider Zee Reclamation.

Last Monday, September 25th, marked the official inauguration of the great dyke across the Zuider Zee from North Holland to Friesland, which is now fully opened for traffic. The inaugural address was delivered by Dr. J. A. Kalff, the Minister for Public Works, and Dr. V. J. P. De Blocq van Kuffeler, Director-General of the Zuider Zee Works, also spoke. On behalf of the contractors a tower built at De Vlieter, the point of closure of the dam, about 90ft. in height, with an observation platform, giving a fine view of the surrounding country, was presented to the Dutch Government. A general description of the Zuider Zee works was given in our issues of August 9th and 16th, 1929, in which reference was made to the entire scheme of reclamation The north-western or Wieringermeerpolder is already under cultivation, and although work on the other sections has been retarded, in view of financial considerations, it has been decided to continue the drainage of the north-eastern polder near to Friesland as soon as the financial situation makes this work practically possible. The Dutch Government has also asked the Netherlands Parliament to vote the first instalment of a credit for the construction of a railway across the dyke, which is designed for a road, a bicycle track, and a double railway track.

An Oil-Electric Tug.

The oil-electric tug "Lectro," which was launched from the yard of Henry Robb, Ltd., of Leith, on Thursday, September 21st, and named by the Marchioness of Linlithgow, has been specially designed for the Thames service of the Union Lighterage Company, Ltd., and will be one of the most powerful vessels operating on the river. The propelling machinery will comprise two 360 B.H.P. Mirrlees oil engines driving B.T.H. generators, supplying current to a 580 B.H.P. propelling motor. Smaller generators will provide current for the electric steering gear, lighting, and other auxiliary services, the whole of the electrical equipment of which is being supplied by the British Thomson-Houston Company, Ltd., of Rugby. The control gear will be directly operated from the bridge, dual bridge telegraphs being employed to control directly the propelling equipment. It is fully anticipated that experience with this new type of vessel under actual river conditions will show an economy in running costs, and will set up a new standard in quick manœuvring capabilities. The tug is expected to be commissioned in a few weeks' time, and special demonstration trials on the Thames are being arranged.

Avon Bridges.

With the placing of a contract for the strengthening of a bridge between Kelston and Weston, the L.M.S. Railway Company has taken the first step in an important scheme of bridge reconstruction on the line between Mangotsfield (near Bristol) and Bath. Under this scheme six bridges carrying the railway over the river Avon on this section of line, together with several smaller bridges on the same route, are to be reconstructed with the object of permitting the use of heavier locomotives than those at present allowed over the line. The Mangotsfield-Bath line of the L.M.S. crosses the river Avon in six places, and in each case the lines are carried over the river by a bridge with two openings. The spans of these openings vary from 75ft. to 106ft. and the central piers in the river consist of cast iron columns supported on screw piles. The main girders are wrought iron of the lattice type, and in four cases there are also wrought iron cross girders, while the other two bridges are of the "deck" type, with the rails directly over the main girders. There are many difficulties to be overcome in the reconstruction of the river bridges, as the traffic on the railway has to be maintained while operations are in progress and at the same time suitable arrangements are necessary for the passage of river traffic. Provision has also to be made in case of floods for the flow of the river to be impeded as little as possible. The superstructures of five of the river bridges are to be entirely reconstructed with new steel main girders and floors of steel and concrete, but in the case of the river bridge near Bath L.M.S. station it is intended to bring the existing main and cross girders up to the required strength. New concrete centre piers are to replace the existing cast iron columns in all six bridges.

Traffic Signals.

Official approval by the Ministry of Transport for the installation of the vehicle-actuated rather than the fixed time type of traffic signal is expressed in a letter recently sent to the Highways Committee of the St. Pancras Borough Council. Reasons for the views held by the Ministry are given in the letter. "This type is more efficient in that it imposes fewer unnecessary delays upon traffic; at the slacker hours of the day this is an important point, since, if vehicles are held up unnecessarily in their path while no traffic is passing in the cross direction, drivers are apt to ignore the signals and proceed on their journey, thus contributing to a disrespect for traffic signals generally." Several important junctions in the St. Pancras area are therefore to be equipped with vehicle-actuated signals. That the views of the Ministry are in agreement with that of many other local authorities is demonstrated by work going on in other parts of the country. Leeds Corporation has, for example, decided to replace existing "time" signals by the "electromatic" type, Edinburgh is experimenting with vehicle-actuated signals, and Birkenhead has just joined the number of towns and cities having the latest type. An interesting reaction also appears to be taking place largely as a result of the development of the "electromatic" signal. At least one of the motoring organisations is urging that such lights should be installed at crossings on big arterial roads instead of the big expensive and complicated islands now common in the London district.

Blowing Up a Viaduct.

A bridge-demolition operation of more than usual interest was carried out at Shottle, some 8 miles from Derby, on Sunday, September 24th, when Royal Engineers from Catterick Camp and Territorial Engineers blew up a nineteen-arch viaduct forming an accommodation bridge across the L.M.S. branch line from Duffield to Wirksworth. The bridge, which was built nearly seventy years ago at a cost of £100,000, had to be constructed in order to obtain wayleave for the building of the railway line which passed through a single arch. It was built by the old Midland Railway Company, and was little used, and in recent years it had to be condemned as dilapidated and unsafe. The Royal Engineers accepted the invitation of the L.M.S. Railway Company to destroy the bridge, and after suitable preparations, including the protection of the track by ballast, operations were begun at 7.30 a.m. on Sunday last. An interesting feature of the work, which extended from the first explosion at 7.30 until the afternoon, was the use of different kinds of charges arranged in different ways. Thus, one group of three arches remained unmoved at the first explosion, a similar group crumbled to the ground, while a third was blown to pieces. It is understood that the Royal Engineers were quite satisfied with the information which was obtained from this practical experience of full-scale bridge demolition.

The Late Dr. Herbert Lapworth.

Civil engineers and geologists alike will learn with regret of the death of Dr. Herbert Lapworth, which took place recently at his home at Sutton at the age of fifty-eight. Herbert Lapworth received his education at King Edward VI. School, at Birmingham, and at the University of Birmingham, and was a pupil of the late James Mansergh, with whom he was engaged on the Elan Valley water supply scheme. During this period he carried out the field work, which he later embodied in an important paper on "The Silurian Sequence of Rhayader," published by the Geological Society of London. After spending some years as resident engineer to various water supply schemes, Dr. Lapworth came to London in 1910, and soon came to be recognised as an outstanding authority on geology as applied to civil engineering. His 1907–8 lectures to the students of the Institution of Civil Engineers on "The Principles of Engineering Geology," will be remembered as models of lucidity and for the knowledge they embodied. Dr. Lapworth was called upon to report upon design and supervise many water supply undertakings, and he also served on several technical committees. He was a member of the Institution of Civil Engineers, a Past-president of the Institution of Water Engineers, a member of the Association of Consulting Engineers, and a Past-secretary of the Geological Society. He had a charm of character which endeared him to a wide circle of friends, who will keenly feel his loss.

The Gas Industry.

In his presidential address, delivered at the annual conference of the British Commercial Gas Association at Bournemouth on Tuesday, September 26th, Mr. William Cash referred to the future of the British gas industry and the necessity of bringing before the public its claim for support, alongside the competitive appeals of the oil and the electrical industries. The sum of two hundred millions sterling was, he stated, invested in the gas industry, and 115,000 people were directly engaged in carrying on the business of the supply of gas to 10,000,000 consumers. Incidentally the industry provided every year large sums of money to pay for coal, constructional works, and the appliances which consumers required, and all that went to provide employment, while as an exporter of various products the industry undoubtedly assisted the export trade of the United Kingdom. The technical efficiency of the gas industries and the sale of by-products had tended to keep the price of gas at a reasonable figure. Referring to the future of the gas industry, and the manufacture of motor spirit as a by-product, Mr. Cash said that there were about 400 gas undertakings, each carbonising 20,000 tons of coal or more a year, but less than 100 of them were making motor spirit. There seemed to him to be in that direction an opening for a very substantial development of a national product.

The New Holborn (Kingsway) Station.

Early on Monday morning last, September 25th, the new Holborn (Kingsway) Station was completed and opened for public service. It now serves both the Piccadilly line and the Central London Railway and is provided with seven fast escalators. Four of these are claimed to be the longest now in use. They work on one shaft and each has a length of 157ft. 7in. The working speed is variable, according to the traffic demands, but at rush hours they can be run at a maximum travelling speed of 160ft. per minute. The new Central London Railway station has been constructed 250 yards east of the old British Museum Station, which is now closed, and over a year and a-half has been spent in constructing a tunnel from the new Holborn (Kingsway) Station to the new Central London Railway station platforms. During the whole of the time the work was carried on without interrupting the train service. The new C.L.R. station is complete with a signal cabin embodying the latest equipment, and a new booking office of the passimeter type has been erected at the Holborn Station. The work has cost approximately half a million pounds, and is expected to bring a material increase in the amount of traffic handled.

Business Efficiency.

At the opening of the Business Efficiency Exhibition at the White City on Tuesday last, Lord Melchett referred to the progress made in the mechanisation of office equipment and commented on the fact that out of the sixty firms represented at the Exhibition most were British. Those who took part in industrial enterprise of any importance, he said, knew very well that if they were less efficient their costs would be higher, their outputs lower, and they would suffer in competition with rivals. With the world moving towards larger units, the larger outputs and quantities required the fullest use of mechanical office assistance, and the latest improvements that intensive thought could provide were absolutely essential to control the larger units. The result of the movements into the larger units would be stability. Stability had to be achieved on a new basis of price levels. Some business men had complained of Government interference, and wanted to be left alone to get on with their jobs. It would, he suggested, be an admirable thing if that could be done, but when they looked round they found that the only cases of readjustment and improvement in the industrial world had been carried out by the Government. Instances of such improvement were to be found in the electrical industry and agriculture. Lord Melchett pointed out that unification was still unrealised in the steel, textile, engineering, and shipbuilding industries, and that the unemployment problem was still unsolved.

The Shipping, Engineering and Machinery Exhibition at Olympia.

No. IV.

(Continued from page 282, September 22nd.)

SIR W. G. ARMSTRONG, WHITWORTH AND CO. (ENGINEERS), LTD.

In the pages of THE ENGINEER, frequent reference has been made to the various products of Sir W. G. Armstrong, Whitworth and Co. (Engineers), Ltd., of Scotswood Works, Newcastle-upon-Tyne, especially with regard to oil-electric traction. Unfortunately, and partly owing to the wide range of manufactures undertaken by the firm, it was found impossible to exhibit at Olympia more in this line than the small oil-electric shunting locomotive illustrated in Fig. 84. The main dimensions of this 0-4-0 locomotive are given in the following table :—

Wheel diameter..	2ft. 9in.
Wheel base	6ft. 3in.
Total weight (working order)	15 tons
Length over buffer beams	13ft. 4½in.
Maximum width	9ft.
Height to roof	10ft. $10\frac{11}{16}$in.

In the frame construction, which is a structure similar to a box girder, considerable use has been made of welding with the object of eliminating the possibility of members working loose. The buffer beams are mild steel plates reinforced by iron castings, which also serve as ballast to give the necessary adhesive weight. Laminated springs of plain, rectangular section are placed inside the frame over the axles.

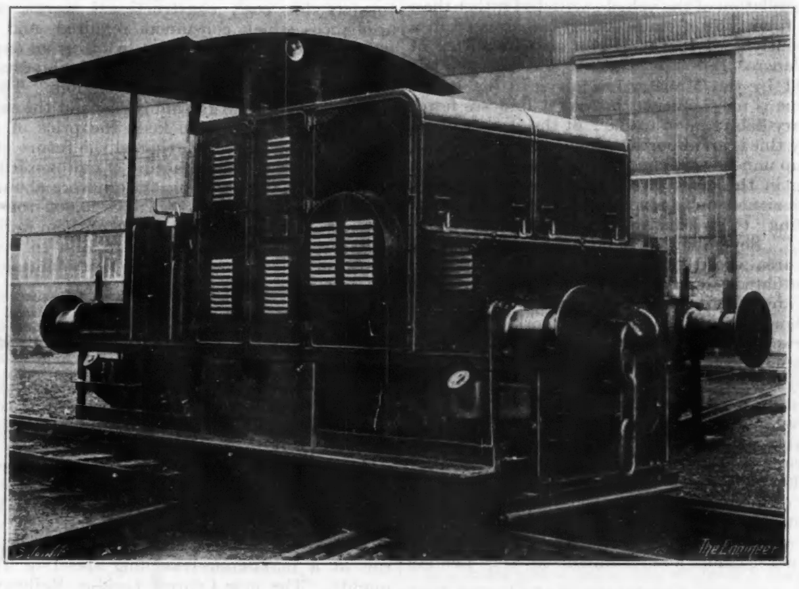

FIG. 84—0-4-0 OIL-ELECTRIC SHUNTING LOCOMOTIVE—ARMSTRONG

Since the engine is of the standard Armstrong-Saurer six-cylinder type, which has been described on previous occasions, it is not necessary to refer to it in detail here. It is direct-coupled to the electric generator and the crank case is bolted to the generator frame. The power unit so formed is carried by three trunnions in rubber-bushed bearings on the locomotive frame. The object of this arrangement is not merely to isolate the locomotive from any vibration, but to protect the power unit from the effects of any strains in the main frame. Compared to the standard engine an over-size sump is fitted. The large oil-cooling surface thus obtained, combined with the large capacity, is found to keep the oil at such a temperature that no special cooler is required. As might be inferred from the engraving, the power unit is mounted with its length across the locomotive, the radiator being on the left-hand side. The traction motor is supported and positively located on cross-stays, and drives the coupled axles through a jack-shaft situated between them.

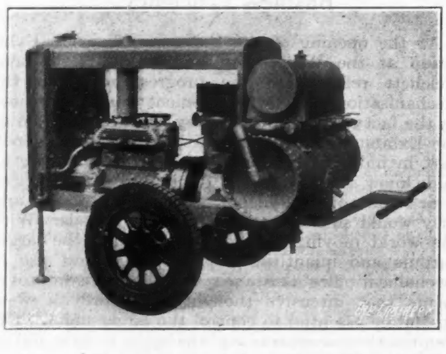

FIG. 85—PORTABLE COMPRESSOR—ARMSTRONG

The manifest advantages of an electric transmission for a "shunter" has led the makers to design a special transmission system known as the A.B.E., which, besides being simple in operation, has the additional merit of being cheap to manufacture. It consists essentially of two electric machines with special windings, a generator and a motor. A special winding on the generator is utilised for starting the engine. Practically the full engine horse-power can be taken through the generator throughout its range of speed owing to the special nature of its windings, and, consequently, any tractive effort required can be obtained merely by opening the engine throttle. Thus, in starting a heavy load the engine speed can be progressively increased until the locomotive moves steadily away with the load. In operation the controls are first unlocked by a small key, the "reversing" switch is then moved to the position "charge," and the "control handle" to "glow", warming the cylinders by glow plugs. After a minute or so, the control handle is moved to "start," when the engine is rotated by the starting battery and commences to fire. The control handle is then moved to "idle." Next the "reversing" switch is placed either in "forward" or "reverse," according to the direction of motion required. Operation of the control handle in much the same way as the accelerator of a motor car will then cause the locomotive to move smoothly away. Almost at once the engine will accelerate up to full governed speed and develop its full horse-power for starting and moving the load. All the controls are duplicated on each side of the footplate, so that the driver can move from side to side. This locomotive was running on a short length of track at the Exhibition, and nearby there was a complete A.B.E. transmission unit laid out for inspection by those interested.

Latterly, the interest of the engineering profession in this country has been concentrated on Armstrong-Whitworth's endeavours to develop the oil-driven vehicles for the railways, and the activities of the firm in other directions has tended to be overlooked by all but those directly interested in such products. In Fig. 85, therefore, we illustrate a neat, new portable compressor unit, introduced at the Exhibition and destined, we understand, to be the forerunner of a complete range of such units. It is capable of delivering 120 cubic feet of free air per minute, against a pressure of 100 lb. per square inch, and runs at 1200 r.p.m. This high rate of revolution has been made possible by so designing the compressor—see Fig. 86—that the delivery valve occupies nearly the whole area of the cylinder head, while the suction valve is placed on the top of the piston. The air velocity through the ports, as given to us by the makers, is 110ft. per second, the lift being 0·06in. The valves are of the inertia-operated ring type, and the clearance volume is 2 per cent. Air passes from the inlet manifold to an annular chamber surrounding the cylinders, and on the downward stroke of the piston is drawn upward through ducts in the body of the piston itself. In the general design of the machine, as many components of the Armstrong-Saurer engine have been used as possible.

An ingenious system of unloading has been devised. As can be seen from the lower drawing in Fig. 87, there is at the side of the twin-cylinder block a chamber containing a tubular valve. This valve is so arranged that its rotation can put the two cylinders into connection with a common transfer passage. Thus, in the fully unloaded position, the air is passed backwards and forwards between the two cylinders. For starting the engine, a hand control wheel is fitted to the end of this valve, which may thus be placed in the "unloaded" position temporarily.

"The Engineer"

FIG. 87—MECHANISM OF COMPRESSOR UNLOADER—ARMSTRONG

The upper drawing in Fig. 87 shows how the valve is operated. Air from the receiver and, therefore, under pressure, acts upon the underside of a weighted pilot valve. If the pressure builds up sufficiently for this pilot valve to be raised, air from the receiver is able to find its way through a connecting pipe to the operating cylinder on the side of the compressor block, and acting beneath the piston therein raises it. By the same motion of the pilot valve the upper chamber of the operating cylinder is placed in connection with the atmosphere *viâ* a ball valve. A third operation is also performed by the motion of the pilot valve. Pressure air passing into a connecting pipe operates a suitable device which throttles down the engine. The reverse operation of reloading is complicated by the necessity for opening the throttle of the engine before the compressor is put on load again. On the reduction of pressure in the receiver the weighted control piston falls. The pipe line to the engine throttle is then opened to atmosphere, and the engine begins to gather speed. The space beneath the piston in the operating cylinder is also opened to atmosphere, while a pipe connection brings pressure air to an "annex" above the upper chamber of the same cylinder. This air, however, cannot gain access to the cylinder by the same path by which air escaped from it, for the way is blocked by the re-seated ball valve. It is forced to find its way past a cone valve, which may be adjusted by an external nut to give a suitable period of delay.

Varley Pumps and Engineering, Ltd.

Two years ago we described and illustrated the action of the Varley pump—see Fig. 88—manufactured by Varley Pumps and Engineering, Ltd., Acton, London. This pump is positive in action and its "displacer," it will be remembered, has a paracyclic motion, the movement being imparted to it by two cranks geared to a common driving shaft and all encased with the pump itself. According to the makers, the pump can, when wet, but not full of liquid, give a vacuum equivalent to 24in. of mercury, and when fully primed can produce a vacuum of 29in. under normal barometric conditions.

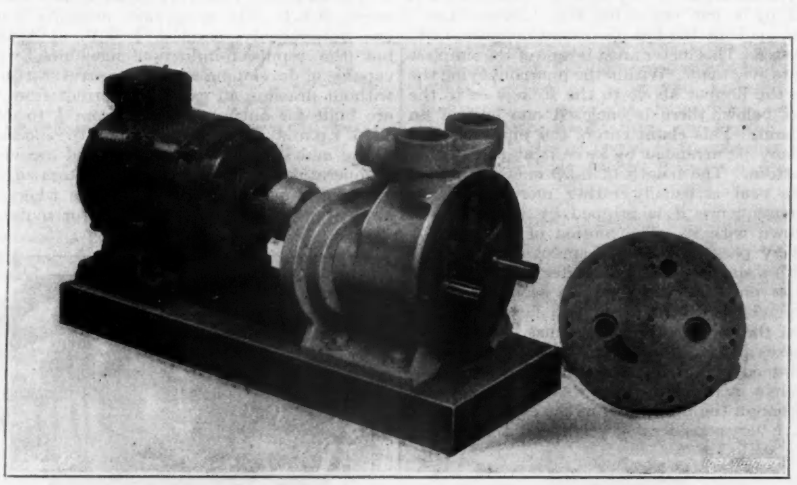

Fig. 88—Motor-Driven Positive Displacement Pump—Varley

In every pump there is included in the front casing the compensating device illustrated in Fig. 90. It will be seen that it consists of a spring-loaded piston working in a cylindrical chamber. The face of the piston is exposed to the discharge pressure and the back to the suction conditions. Its function is to absorb any slight fluctuations of flow of the liquid on either the delivery or the suction side, and it gives, it is claimed, a smooth flow without the use of air vessels.

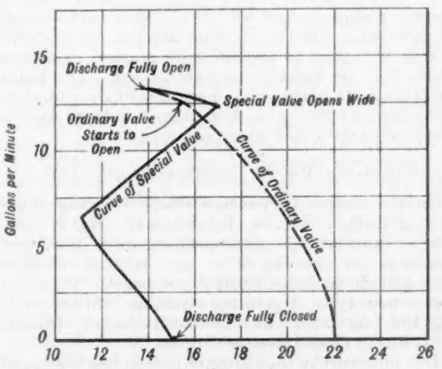

Fig. 89—Characteristics of By-Pass Valves—Varley

For use where the pump is utilised for pumping petrol from underground tanks, a special form of by-pass valve has been developed. The makers found that with an ordinary spring-loaded valve it was impossible to obtain full by-pass conditions without the pressure rising to 40 per cent. above the ordinary delivery pressure. Apart from the loss of efficiency entailed by this rise of pressure, it has a limiting effect upon the maximum delivery of the pump in districts, of which there are several, where it is not permissible to use a driving motor for petrol pump service of more than ½ H.P. In the graph reproduced in Fig. 89 the characteristics given by the maker's special by-pass valve are compared with that of an ordinary by-pass. It will be seen that the ordinary valve sends up the delivery pressure from 14 lb. to 22 lb. per square inch. The new by-pass does not begin to open at once when the discharge nozzle of the delivery pipe begins to close, but when it does, it opens fully and causes the pressure to drop rapidly to about 11 lb. per square inch, with a corresponding reduction of the quantity discharged through the delivery pipe. Subsequently with the by-pass full open the full by-pass occurs at 15 lb. per square inch. We understand that this result is obtained by the use of that type of valve which provides, when closed, a smaller area for the pressure to act upon than when open.

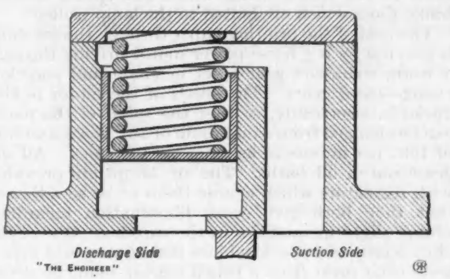

Fig. 90—Compensating Device—Varley

New Process Welders, Ltd.

Spot welders of various types and suitable for heavy and light welding were exhibited by New Process Welders, Ltd., of Scotts-road, Southall, Middlesex. Machines rated at 2 and 4 kVA are supplied for bench mounting, but if desired they can be mounted on fabricated light steel pedestals or stands; whilst 8 and 16 kVA welders are mounted on cast iron pedestals, as shown in Fig. 91. The primary of these machines is wound on the ring or gramme principle, and is entirely distributed around the core. Two bronze castings encase the primary winding and core, and form a single turn secondary winding which supplies current to the electrodes, one-half of the casing being stationary and the other movable. In Fig. 92 A is the stationary part of the secondary and B the moving part attached to the movable electrode; C is the iron core with an axle in the centre.

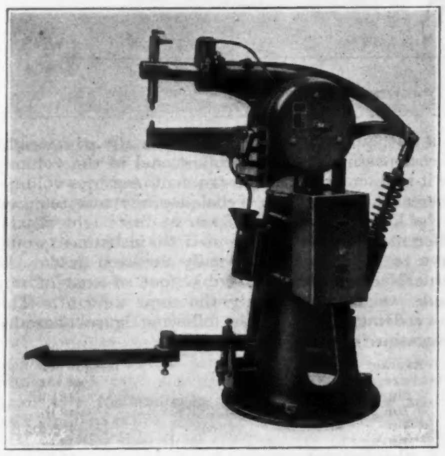

Fig. 91—Spot Welder—New Process Welders

The fixed electrode is, of course, attached to the fixed part of the casing. With this form of construction magnetic leakage is said to be completely eliminated and with standard arms the power factor is over 0·9. In the case of the 2-kVA machine, the electrode arms are cast solid with the bronze casing, whilst on the 4, 8, and 16-kVA machines the lower arm is bolted to a T-slotted face plate cast solidly with the fixed half of the transformer secondary and can be moved up or down or sideways. The upper arm on these machines is telescopically mounted on the moving part of the transformer, and the foot pedal operates on the moving part of the secondary through an adjustable spring and switch. The primary winding is provided with from three to five tappings for slightly varying the secondary voltage to meet requirements.

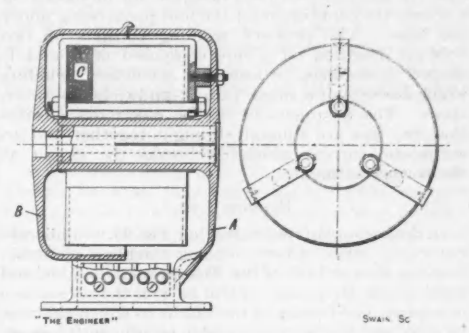

Fig. 92—Details of Welding Transformer

The most interesting feature of these spot welders, however, is the automatic controller, which enables higher voltages to be used than usual, and consequently makes it possible to increase the welding speed. It can easily be adjusted to meet variations of materials, and enables unskilled operators to make perfect welds. Controllers of this type are also supplied separately for use with any other make of spot welder. The principle of the "D" type controller, as fitted to the 8 and 16-kVA spot welders, will be understood from Fig. 93. After the initial movement of the machine pedal has closed the welding tips on to the work, further movement applies the spring pressure and afterwards the pedal contacts A are closed. This energises the contactor coil B, which attracts the rocker arm of the contactor and closes the circuit at C, thus energising the transformer, and the work between the electrodes is welded. When the weld has been correctly made, the reduced resistance gives rise to a current surge in the electrode arms, and the contacts D of a magnetic relay are closed, thus energising the coil E of an electric relay in the controller case. The arm of this relay is therefore attracted, and breaks the contactor coil circuit at F, whilst the sustaining switch G closes and keeps the relay coil energised so that the contactor remains in the "off" position until the pedal is lifted. The release of the pedal breaks the relay coil circuit at A, and the controller is automatically reset for the next weld. Naturally the time taken to complete a weld

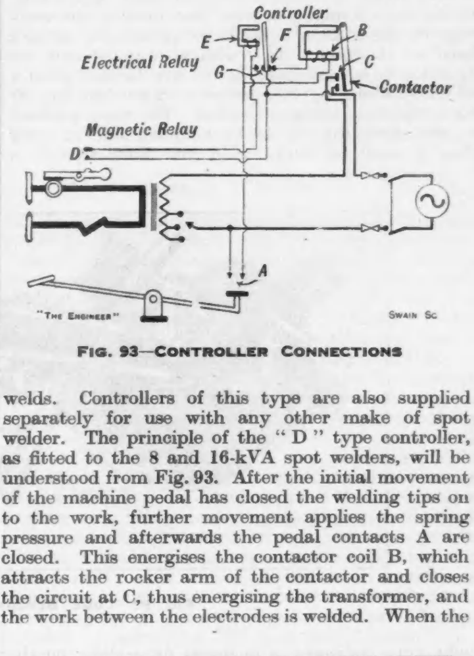

Fig. 93—Controller Connections

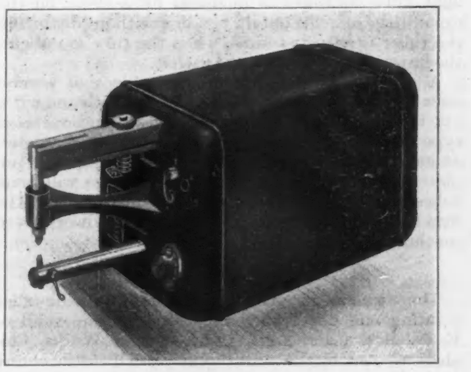

Fig. 94—Bench Spot Welder

depends on the thickness of the metal, and by means of a cam which controls the gap between the iron ring which surrounds the upper electrode and the magnetic relay armature, the necessary adjustments of the relay can easily be made. Graduations on the cam facilitate the subsequent resetting of the machine.

An entirely new spot welder developed by the firm for use in connection with the manufacture of electric lamps, wireless valves, and for light wire and sheet metal work is shown in Fig. 94. It will be gathered that the machine has been designed for mounting on a bench, the connection for the foot pedal being under the base. The primary winding consists of two bobbins mounted on a core composed of E and I-shaped stampings, whilst the secondary winding which consists of a single turn is sandwiched between them. The arrangement of the electrodes ensures that the tips are squarely brought together and an automatic current controller breaks the circuit at the correct moment.

HILMOR LTD.

In the accompanying engraving, Fig. 95, we illustrate one of the range of tube bending machines manufactured by Hilmor Ltd., of 108, Euston-road, London, and exhibited at Olympia. It will be seen that it consists of a wheel-like former of the radius to which the tube is to be bent and interchangeable rapidly with formers of different sizes, a bending arm carrying a roller, and a guide, formed with a slot of the diameter of the tube to be bent, which fits between the roller and the tube. In action, of course, pulling back the arm causes the tube to be bent around the former. The machine is equipped with a special patented feature. It will be seen that the position of the roller relative to the arm can be varied by a screw and nut motion. Thus, for any particular tube and former the arm can be placed in any position over quite a wide arc before the tube was bent. Referring to the engraving, the nearer the arm approached the observer before bending commenced, the easier would it be to bend the tube owing to the higher leverage about the point of bending. It has been found, however, that making the work easy in this fashion is liable to wrinkle the interior bend of the tube. In a similar way, should the operator be so unhandy as to give himself greater effort by arranging the arm to start bending too far back, the tube will be distorted. The mean position is, therefore, the one to be adopted, and in order that it may be found with the least trouble a light brass indicator is mounted on a slider on the top of the arm. To obtain bending without distortion the roller is adjusted until, when the tube is unbent, the brass indicator is parallel with it.

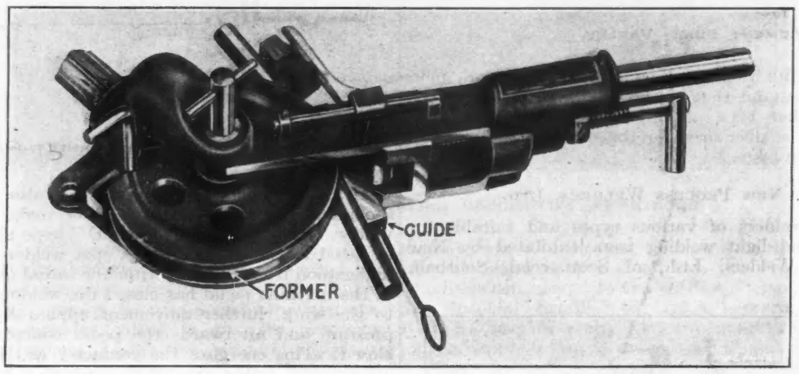

FIG. 95—TUBE BENDING MACHINE—HILMOR

A number of hand-operated machines of several sizes were to be seen on the stand, both with and without the indicator device. The largest hand-operated type will bend copper tubes up to 2in. in diameter, 16 gauge, without filling, and steel tube up to 1½in. diameter, while the smallest of the range will bend tubes ¼in. outside diameter to a radius of ¾in. The firm also makes ratchet-aided and power-driven machines.

E. N. MASON AND SONS, LTD.

There was an extensive collection of drawing-office printing and developing apparatus on the stand of E. N. Mason and Sons, Ltd., Arclight Works, Colchester. Among the most recently produced machines is the New Century continuous photo-copier, shown in Fig. 104 on page 310, which has been specially designed for printing the new style of dye-line prints that need a very even distribution of exposure to the light. This machine is made in two styles, one with a single arc lamp and the other with two. That illustrated is of the latter type. The lamps run on tracks so placed that the arc crater is at the centre of curvature of the bent glass developing platen, so that there is an even distribution of the light over the whole surface. They are driven, independently, by little one-twentieth horse-power electric motors, mounted on the lamp carriage. The power is transmitted through worm and worm wheel gearing to a crank which operates in a specially shaped crosshead, providing for a uniform movement across and "dwell" at the ends of the run, in order to compensate for the lack of "back rays" at the edges of the print. In order to overcome the natural momentum and to bring the lamp trolley to rest without shock, two adjustable brakes are fitted. These brakes comprise curved steel tracks fixed to the frame along which run spring tension brake shoes which are bolted to the lamp trolley.

The feed of the printing paper through the machine is effected by a ¼ horse-power motor driving through a worm reduction gear a set of chain and sprocket change-speed gears. The speed of the motor is also variable, electrically, so that the speed of the paper can be changed from a minimum of 2in. to a maximum of 15ft. per minute in as many as 100 steps. All the gears run in oil baths. The arc lamps are provided with regulators which enable them to be so adjusted that they both give equal illumination regardless of any slight inequalities in the carbons. One of the chief merits of these machines is that they will give a good clear print from a pencil tracing made on detail paper.

Besides several other types of printing machines, there were on this stand a number of developing machines, print trimmers, and other accessories of the drawing-office.

THE LEA RECORDER COMPANY, LTD.

On the occasion of the last Shipping, Engineering and Machinery Exhibition at Olympia we described and illustrated by a line engraving the "Romer Lea" coal meter, made by the Lea Recorder Company, Ltd., of Manchester. This meter must be one of the simplest instruments ever made. Within the pipe conveying the coal from the hopper above to the stokers or to the pulverisers below, there is enclosed one half of an endless chain. This chain enters the pipe near the top and may be arranged to leave it at the side or at the bottom. The length of its immersion in the descending coal is usually rather more than 6ft., and in consequence it is gripped by the coal and carried down with it. The motion of the chain is measured by passing it over a sprocket wheel connected with a suitable form of counter.

It will at once be seen that the accuracy of the meter depends in the main on two factors. First, the grip of the coal on the chain must be such that no slip takes place. That that desiradatum is certainly attained was easily proved by a visit to the stand where a meter of the type was shown in operation. Although the immersion of the chain was only about 4ft., a very considerable weight could be applied to it without any sign of slip. Secondly, the weight of coal passing must be proportional to the volume, for it is obvious that the instrument measures volume, whereas it is the weight of coal passing that is required to be known. It might seem at first sight that if different grades of coal were used, the instrument would have to be calibrated specially for each grade. In actual fact, however, a cubic foot of coal of any grade weighs very nearly the same amount. This fact is demonstrated by the following figures of graded Lancashire coal:—

Average size.	Weight per cubic foot, dry.
2in.	48¼ lb.
1in.	48 lb.
½in.	48¾ lb.
¼in.	46 lb.
Peas and dust	47 lb.
Average	47·6 lb.

Nor is the variation of weight per cubic foot of different classes of coal very great. The average weight per cubic foot of seven coals from different districts was found to be 48·1 lb., the highest figure being 52·1 for Welsh and the lowest 46·8 for Derby coals. It will be seen therefore that this method of measurement by volume can be accurate. It also has the advantage of being totally unaffected by surface moisture, for the water contained in the coal which may have so large an effect if the material is weighed, has no influence upon its volume.

Another instrument which was exhibited on the stand is intended for the measurement of water flow. It is illustrated in Fig. 103, page 310. A float in the tank from which the water flows over a calibrated weir or V notch carries an upright bar. On the bar are mounted the two small gear wheels of the well-known "Lea" integrator. It will be remembered that this integrator consists of two drums cut with gear teeth, one of which is driven at a constant speed. In the instrument under discussion a tiny synchronous A.C. motor operated from the supply mains is used. The gear teeth do not cover the whole surface of the driven drum, but are cut away in a form more or less that of a helix, and depending upon the characteristics of the weir, V notch, or orifice, &c. Thus, at the top there are gear teeth all round the drum, and at the bottom no teeth at all. Connection between the two drums is made by two small intermeshing gear wheels, one of which meshes with the driven drum and the other with the second drum which is connected to a counter, the mechanism of a recording pen, or in any other way required. Thus upon the position of the two small gear wheels depends the proportion of the time during which the second or recording drum is rotated by the driven drum. In the instrument under review the small wheels are mounted on a rod attached directly to the float, while the box in which the mechanism is contained bears in its top a counter.

Many others of the various instruments made by the firm were to be seen on the stand.

POWER CONTRACTS (BATWIN), LTD.

A display of split-phase, induction-repulsion, D.C., and capacitator motors was to be seen on the stand of Power Contracts (Batwin), Ltd., of 138, Southwark-street, S.E.1. The split-phase machine is made for one output only, namely, ¼ H.P. at 1428 r.p.m., but the repulsion-induction machines, which are capable of developing a very powerful starting torque without drawing an excessive current from the line, are built for outputs ranging from ⅙ to 3 H.P. at 1425 r.p.m. They are fitted with special brush-lifting and short-circuiting gear, and are very silent in operation. Spring-mounted motors of ⅙ and ¼ H.P. are supplied for use in places where absolute silence is required. The capacitator motors, which are also claimed to be absolutely silent in operation, are provided with an electrolytic condenser, and are said to work with an excellent power factor and efficiency.

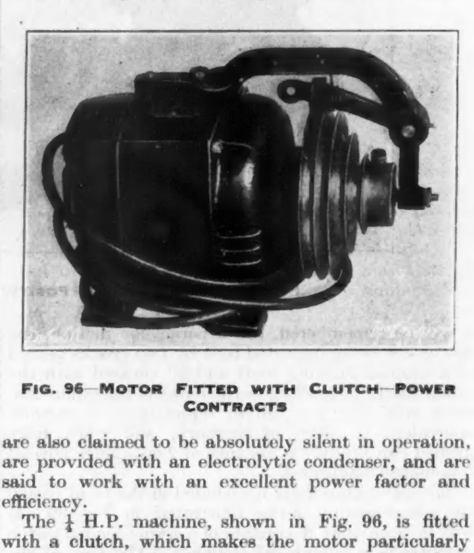

FIG. 96—MOTOR FITTED WITH CLUTCH—POWER CONTRACTS

The ¼ H.P. machine, shown in Fig. 96, is fitted with a clutch, which makes the motor particularly suitable for driving sewing machines, coil winders, &c., which demand considerable speed variation. The clutch unit incorporates an aluminium pulley with two different sized grooves. The driving member makes contact with the driving part through a leather ring, and the pressure upon it can be varied at will according to the pressure applied to a lever which may be hand or foot-controlled. The motor shown is a standard split-phase machine, wound for 220 volts and 50 cycles, but other windings may be provided to meet special requirements.

PRECISION PHOTO PRINTING PLANT, LTD.

On the stand of Precision Photo Printing Plant, Ltd., Salisbury House, London-wall, E.C.2, there were a number of photo-printing and developing machines for drawing-office use, several of which have already been described in our pages. There was also a new type of printing machine, illustrated by Fig. 102, page 310, which has been specially designed for printing Ozalid positive copies.

It is noteworthy that some objection has been made in the past to these positive prints, when made on wide paper in the normal travelling arc lamp machine, on account of a striped effect at the edges, which may be so acute as to make the print difficult to read. This effect is produced by the lack of sufficient exposure to the light at the edges of the print where the lamp reverses its travel, but has been overcome in the case of the machine under review by the simple expedient of slowing up the speed of travel of the lamp at each end of its stroke. The lamp is mounted on a carriage and is moved by a chain running over sprockets on either side of the machine. One of the sprockets is driven by a little electric motor and three-speed gear-box by a crank pin on a shaft engaging with a slot in a disc on another shaft. The two shafts are set out of alignment, so that as the pin drives the disc round it must slide in the slot and consequently hasten the travel of the lamp during the middle part of its stroke, and slow it up at the ends. At our request, some tracings, which were not very clearly made, were copied in the machine and developed, and we found them in each case as well defined as the original.

CHARLES WESTON AND CO., LTD.

On the stand of Charles Weston and Co., Ltd., of Lincoln Chambers, Portsmouth-street, London, W.C.2, there was shown a wide range of "Gits" oil seals, the efficiency of this fitting being demonstrated by a bearing running in water, which showed no trace of oil leakage from the sealed bearings. A practical example of the application of the oil seal was seen in a 10in. worm reduction gear by Henry Wallwork and Co., Ltd., of Manchester. Two examples of the use of oil seals are illustrated in Fig. 97 herewith. The seal is a ring formed of a heavy steel metal pressing of rectangular cross section, the outside diameter of which is finished to a tolerance of plus or minus one-thousandth of an inch, thereby ensuring an oil-tight joint when the seal is pressed into the bearing housing. As the drawing clearly indicates, the sealing element consists of a leather ring of special shape, which has a long tapered lip at its inner edge. This lip is pressed against the shaft by a spring-loaded, cone-shaped washer, which also serves the purpose of shearing off the oil film and preventing the escape of oil from the casing. The firm also showed examples of "Raymill" grub and cup screws, which are furnished with an hexagonal hole on the head of the screw, in which a tommy bar of hexagonal section is used, and are supplied in different metals and patterns. Various types of "Gits" oil cups and wick feeds for special purposes were also on view.

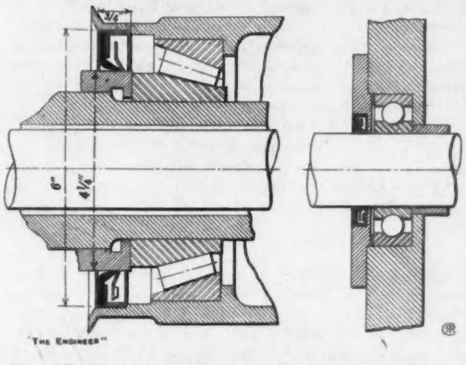

FIG. 97—ARRANGEMENTS OF "GITS" OIL SEAL—WESTON

MARINE ELECTRICAL EQUIPMENT COMPANY, LTD.

Wireless apparatus for use at sea was shown by the Marine Electrical Company, of Gambrell Works, Merton-road, Southfields. The firm's $\frac{1}{2}$-kW (anode rating) radio-telegraph marine installation is claimed to cover ranges on interrupted continuous wave telegraphy equal to those obtained with much more powerful sets, and to meet all requirements in the 600 m. to 800 m. band, even in the case of large vessels. Provision is also made for continuous wave transmission. The main controls include the transmit-receive switch, a combined CW/ICW full-power/reduced-power switch, and voltage controller, together with a volt-meter and aerial ammeter, all mounted above the receiver and directly in front of the operator. The transmitter wave length can be changed instantaneously by the movement of a single switch, while a separate control enables a small change of wave length to be made under heavy interference conditions. Power is obtained from a motor alternator set designed to suit the ship's D.C. supply, and normally fitted in a cupboard under the operator's table, together with an automatic starter, the starting switch and field regulator being mounted on the control unit. The A.C. supply system is used in preference to the generation of high-voltage D.C., owing to the difficulties generally experienced with high-voltage commutators at sea. Provision is made for emergency working as required by the Board of Trade.

The receiver complies with the regulations for compulsorily fitted ships and meets all the requirements for normal marine working. It covers a wave range of from 15–20,000 m. without sacrificing efficiency on any particular wave length, and gives ample selectivity. Special arrangements are incorporated to eliminate broadcast transmissions and other interferences when receiving on the 600–800 m. wave band. An efficient volume control is also provided. The full wave range is obtained by the operation of the wave change switch without changing coils. Limitations of space will not allow us to describe all the wireless apparatus shown by this firm, and it must suffice to refer to some of the remainder of the exhibits very briefly. A short-wave transmitter attachment shown has been developed to form an addition to the standard radio-telegraphic installation described, and in combination, where necessary, with a long wave attachment, it will not only cover all marine telegraphic requirements, but is said to make the complete apparatus far more economical and efficient in working than a main high-power installation. When a complete short-wave equipment is required to work independently of the main medium wave apparatus, the short-wave attachment mentioned is supplied as an independent installation, with motor alternator control and power units and receiver.

The equipment shown in Fig. 105, page 310, is capable of a performance similar to that of the standard radio-telegraph set described, and is also capable of transmitting speech over a distance of 400 miles or more, according to the type of aerial employed. It is therefore suitable for whaler and trawler depôt ships, which need to communicate on telephony with stations which do not have skilled operators, in addition to working on the normal ship-to-ship and ship-to-shore service on 600–800 m. The receiver may be of a simplified type, covering a restricted wave range, but the standard 15–20,000 m. receiver is supplied if required. Provision for emergency working is made when necessary and the transmitter wave range is capable of adaptation to the particular service. Other exhibits were a low-power radio-telephone installation for communication with the Post Office coast stations, a lifeboat installation, a long-wave receiver, a mobile radio-telegraphic-telephone equipment, and the marine direction finder shown in Fig. 106, page 310, in which the rotating loop system has been adopted on account of its simplicity and freedom from errors. The aerial winding is enclosed in a heavy copper tube forming an octagonal frame. In order to facilitate operation, and to enable bearings to be taken accurately and rapidly, the receiver is mounted on the lower tube above the scale and hand wheel, and directly in front of the operator. The receiver is said to be highly sensitive and selective, and to enable bearings to be obtained within half of a degree. A small vertical aerial is used, in addition to the frame, and "sense" is determined by a simple device. After calibration, quadrantal errors are marked on a dial adjacent to the bearing scale, thus enabling the operator to determine the corrected bearing without referring to charts.

SUPER-CENTRIFUGAL ENGINEERS, LTD.

Two centrifuges, both shown by Super-Centrifugal Engineers, Ltd., of Sharples House, Grosvenor-road, London, are illustrated in the engravings Fig. 101 on page 310 and Fig. 98. One is for large-scale production purposes, while the other is intended for use in the laboratory. The big machine has a basket 65in. in diameter, and it is capable of operating continuously, automatically discharging the solids while the basket is running at full speed. Either the solid or the perforated type of basket may be fitted. As a drainer this machine is applied to the dehydration of crystals and granular materials, while the sedimentation principle with a solid basket is applied in those cases where the suspension in a liquid has poor filtering qualities; for example, where the particle size is very small or is of a slimy nature.

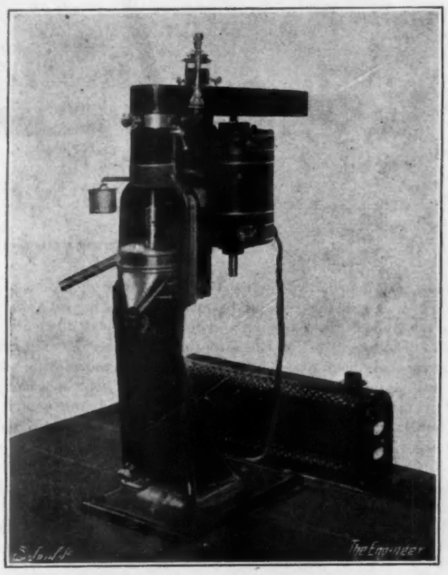

FIG. 98—LABORATORY CENTRIFUGE—SUPER-CENTRIFUGAL

Whilst the basket of the machine is operating at its full speed, the dried crystals can be unloaded and discharged automatically through a chute, in the bottom of the machine, by a simple mechanical operation of a knife gear driven from the main shaft. This gear is to be seen on the upper right-hand side of the engraving. When operating as a sedimenter, the supernatant liquid is removed from the basket of the machine continuously, without reducing speed, by the special decanting pipe, the controls for which may also be seen in the engraving. The material to be treated is fed into the machine on to the lower periphery of the basket. That portion of the feed inlet pipe projecting into the basket is varied in shape according to the problem to avoid turbulence in the liquid layer, especially when the separation of colloidal substances, such as sludges, is called for and where any turbulence must be rigorously avoided. It is claimed that by variation of the design of the inlet pipe and automatic decanting gear a perfectly clear supernatant liquor can be obtained..

The little centrifuge for laboratory purposes is driven by a $\frac{1}{4}$ H.P. electric motor at a speed of approximately 30,000 r.p.m., and the centrifugal force obtainable is about 40,000 times the force of gravity. Three types of bowl may be fitted. All are 2in. in diameter by 9in. long, and hold about 300 millilitres of liquid. They are fed from below on the axis of spin. The clarifier bowl has one central outlet at the top and is used for the removal of suspended solids which are retained in the bowl while the liquid is run off. A separator bowl with two outlets at the top, one central and one draining from the side of the bowl, may be used for the separation of emulsions of immiscible liquids. The third type of bowl has no outlet and is arranged for handling small amounts of liquid in batches.

BENTLEYS.

When describing the Thornycroft-built motor yacht "Trenora" in our issue of August 4th, we made brief mention of a new low-pressure system of sewage ejection for marine purposes which was designed and fitted by Bentleys, of Hull-road, York. A pair of ejector units arranged either for marine or land service were exhibited by the firm at Olympia. They are illustrated in Fig. 100 on page 310. The ejector is of an improved pattern, for which patents are pending, and it works at a lower air pressure than is generally used for sewage ejection. The supply of injection air is automatically controlled by electrically operated solenoid mechanism, which is small and compact. The whole of the plant, as will be seen from our illustration, takes up very little space, and is complete with its own motor-driven compressor, and forced feed lubrication to all working parts. By means of the individual motor drive, the ring main system of air supply is entirely dispensed with, and a further economy in operating air is effected by the adoption of a closed circuit air system, which has also the great advantage that there is no discharge to atmosphere of the operating air from the injector unit. Special arrangements are made for independent operation of either injector units or their working together. The "Trenora" plant is operated by a $\frac{1}{2}$ horse-power motor, and is designed to deal with 2000 gallons of sewage and waste water per hour. A slightly larger capacity plant was exhibited at Olympia, and was shown in actual operation, the practically noiseless working of the units being a noticeable feature.

GENERAL POST OFFICE.

The British Post Office was showing an interesting collection of electrical communication apparatus. There were examples of private branch telephone exchanges which provide facilities for internal communication in offices, works, &c., and for connection with the public telephone system. Visitors to the Exhibition were able to send radiotelegrams free of charge to friends on board passenger ships of the British mercantile marine, which can be reached through British Post Office stations. Among the exhibits of more technical interest was a voice delay apparatus designed to give a second and a-half delay between transmission and reception. The apparatus consists of a steel tape band driven by an electric motor. A coil surrounding the tape is connected to a microphone and amplifier, and speech currents in the former produce a magnetic field in the tape, which passes through a reproducing coil. The varying field acting on this coil produces a varying voltage which is amplified and applied to a loud-speaker, the tape being subsequently demagnetised by means of a 7000 cycle oscillating coil.

Cable pairs to London-Southampton, London-Bristol, London-Cardiff, Cardiff-Birmingham, and Birmingham-London were joined together to form a 1000-mile circuit. Arrangements were made to enable visitors to test the telephonic properties of the line, which proved to be remarkably good. The apparatus at Olympia was fitted with an echo suppressor, and a repeater, which could be switched in and out, in order to demonstrate their effects as regards volume and audibility. Experience has shown that on such long circuits an echo suppressor is essential, as in its absence the echo is so bad that normal conversation is impossible. Fifteen repeaters were included in the circuit.

Two teleprinters were shown for "telex" service, in which the subscriber asks for or dials a telephone number in the ordinary way, and on being connected asks the subscriber at the distant end to switch in teleprinter. The message is then typed by the calling subscriber and is reproduced on the teleprinter at the other end of the line. As the signals consist of a combination of impulses using 300 cycles as the basis tone, there is no difficulty in using teleprinters on ordinary telephone lines. In addition to the commercial apparatus, a loud-speaker and oscillograph were connected across the line to enable visitors both to see and hear the transmitted impulses.

Various types of submarine cables were on view, including a sample of the discontinuously loaded trunk channel cable. A model of the cable ship "Monarch" was also exhibited. Other exhibits relating to telephony were automatic telephone apparatus and a radio speech secrecy device. To obtain secrecy on overseas radio telephone calls, bands of speech are filtered and interposed according to pre-arranged codes, which are changed at frequent intervals, with the result that listeners other than those actually using the system are unable to interpret the messages.

A mercury vapour rectifier shown has been designed for use with valves requiring a high-tension D.C. supply of approximately 10,000 volts. Its special feature is its high efficiency as compared with that of an ordinary vacuum-type rectifier, owing to the low anode cathode impedance brought about by the bombardment of mercury molecules by negative electrons given off by the cathode. More negative electrons are knocked off each molecule than the number which bombard it, and the emission is therefore increased, whilst displaced positive ions are attracted to the cathode, thus partly neutralising the "space charge." The net result is a considerable reduction of anode-cathode impedance, with a resultant reduction of wasted power. The bombardment of the cathode by positive ions, however, tends to shorten its life, and the proportions of the cathode are, therefore, made relatively massive, and it is generally worked at low voltage and with heavy current.

Among the valves shown for use in transmitters was a 500 kW unit for working at anode pressures up to 18,000 volts, and as used in the Rugby wireless station for world-wide communication. It has six filaments, each consuming 75 ampères at 32 volts, the emission being 100 ampères, and the amplification factor 45. The copper cylindrical anode, which is 8in. in diameter and 22½in. long, is cooled by a water jacket, the water being distilled to reduce electrical leakage. The grid connection is led out at the side of the glass bulb, and the grid itself is supported by four cylindrical quartz insulators. The glass-copper seal between the anode and envelope is cooled by an air blast in order to prevent any tendency to fracture as the result of the difference in the coefficient of expansion of copper and glass. As a further safeguard extremely thin copper is used. While the grid connection is not artificially cooled, the filament seal is cooled by means of water.

Another interesting valve was a 500-watt "Heptode" valve, as used as an amplifier in short-wave transmitters. The object aimed at in the design of this valve has been to prevent self-oscillation as the result of back coupling between the anode and grid, the frequency being determined by the transmitter drive which generally takes the form of a crystal. All the electrodes required by the balanced push-pull arrangement are contained in the single envelope, the general construction being very rigid to prevent any relative movement of the electrodes. The grids are composed of molybdenum and the filaments of thoriated tungsten, the filament current being 20 ampères and the emission 750 ma. The anode voltage is 3000, and frequencies up to 20 megacycles are obtained.

THE UNITED STATES METALLIC PACKING COMPANY, LTD.

Besides a fine display of rod packings and piston rings with which the name of the United States Metallic Packing Company, Ltd., Soho Works, Bradford, is familiarly associated, this firm showed some steam traps of the type illustrated by Fig. 99. This trap is intended for draining vessels at or below atmospheric pressure, and has a definite pumping action, the force for which is supplied by a separate connection to a steam or compressed air main having a pressure of about 30 lb. per square inch.

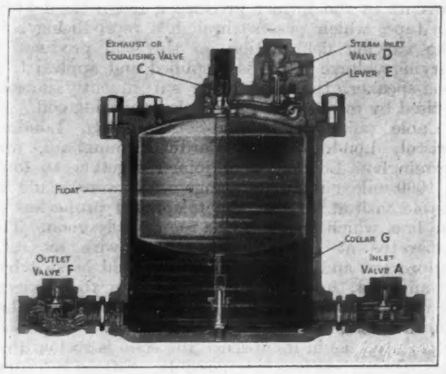

FIG. 99—STEAM TRAP—U.S. METALLIC PACKING

In the event of the vessel to be drained having a pressure below that of the atmosphere, the top of the trap is connected with the vessel by an equalising pipe, so that, with a head of, say, 2ft., the water will flow into the trap under the influence of gravity. It enters through the non-return valve A, and gradually fills the body of the trap. The float B rises with the water and ultimately closes the equalising valve C. Immediately afterwards, by pressing up on the lever E, it opens the live steam valve D. The steam then forces the water out through the non-return valve F. The float sinks again, but the equalising valve is held closed by the internal steam pressure, so that the steam cannot get back to the vessel being drained, and thus destroy its vacuum. The steam valve closes, but the expansion of the steam continues to displace the water. When the float sinks so far as to sit on the collar G, its weight pulls open the valve C, and equilibrium of pressure is re-established in the trap and the vessel. The cycle of operation is then repeated. In cases where the vessel to be drained is open to atmosphere, the equalising pipe is not required, and the valve exhausts into the open. The trap gives a quite definite discharge at each cycle and, consequently, can be used to measure the amount of condensate being handled. A convenient way of doing this is to connect a pressure gauge with the top of the trap—a tapped hole is provided for the purpose—and to count the pulsations of pressure registered. The trap is made in three standard sizes capable of discharging from 150 to 700 gallons per hour.

(To be continued.)

Letters to the Editor.

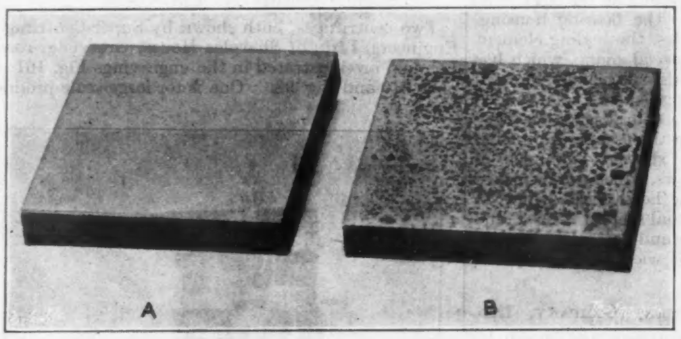
CYLINDER WEAR AND LUBRICANTS.

SIR,—The Report of the Institution of Automobile Engineers Research Committee, published in your edition of June 23rd, indicates clearly the harmful effect of rusting or corrosion of the cylinder wall by moisture condensed from the products of combustion of the fuel.

The beneficial effect in reducing cylinder and piston ring wear of incorporating a small amount of free fatty acid into the lubricating oil is apparent from the engine tests described in the latter part of the Report.

This protective action of oils containing traces of free fatty acid is, of course, strictly in accord with modern chemical theory, the presence of the Polar group in the fatty acid causing the oil to adhere more firmly to the metal than is the case with ordinary mineral lubricating oils. Confirmation of the superior adhesion of such oils has recently been found by various physical measurements, notably the contact angle method and the heat of wetting of metallic powders by oil, the former test being used by Von Dallwitz-Wegener and the latter by Bachmann and Brieger. It can be shown mathematically that the adhesion of a liquid to a solid can be measured by observing the angle of contact of the liquid resting on a metallic surface—the smaller the angle the greater the adhesion. The contact angle at a metallic face is much smaller for an oil containing oleic acid than for the pure hydrocarbon oil.



TEST FOR LUBRICATING OILS

Confirmation of the greater work of adhesion by the former type of lubricant has also been found in the greater heat of wetting when finely divided metallic powders are shaken with the oil.

The photographs attached show the results of a very simple test for comparing two lubricating oils for their relative power of protecting metallic surfaces from corrosion by water. Flat polished plates are smeared with the oil and then exposed for a few minutes to an atmosphere of condensing steam (water boiling in a beaker). The plates are allowed to stand untouched over night and then washed with a solvent. The plate B has been oiled with an ordinary mineral lubricating oil and has badly rusted in spots, while A previously coated with the same oil containing 1 per cent. of a mixture of the higher fatty acids has been protected from corrosion and is almost unattacked.

DIVING AND THE YOUNG ENGINEER.

SIR,—Referring to the interesting article on this subject in your issue of September 15th, we would mention that we have been giving diving instruction in one of our large tanks in our experimental department here for nearly thirty years.

Many young engineers, and a few older ones, have taken advantage of the course, which includes (1) a talk on the construction and functioning of the diving apparatus; (2) a lecture on deep diving with special regard to decompression; (3) not less than three dives under the supervision of competent divers.

Usually after the third dive the student is quite capable of diving at greater depths in open water.

For the engineer who is more interested in compressed air in connection with caisson sinking, &c., we offer similar facilities, the practical part of the course in this case being given in one of our steel air lock chambers. In other sections we produce high altitude and poison gas conditions, and demonstrate the appropriate apparatus for combating them.

SIEBE, GORMAN AND CO., Ltd.,
ROBERT H. DAVIS, Managing Director.
London, S.E.1, September 20th.

SIR,—In reference to your leading article on "Diving and the Young Engineer," in your last week's issue, allow me to point out that most of the students in this School since the year 1879 have received practical instruction in diving and have obtained certificates from Messrs. Siebe, Gorman and Co., in which are embodied the following:—"has received instruction in under-water diving in our tank, and is now, in our opinion, capable of making examination of subaqueous work in connection with Harbours, Docks, Bridges, &c."

MONEY *versus* MAN.

SIR,—I should like to endorse the excellent letter sent by Mr. M. Jacklin, which appeared in your issue of the 15th inst.

Money, an artificiality (*i.e.*, it is a man-made device), has become a Franckenstein. It should be the servant; it has become the master. Most of us are familiar with Mr. Norman's confession.

I believe that the engineer, who by his training is a realist, will have to tackle this problem of distribution. It is his duty to do so.

The American experiment is not being conducted by engineers, or at any rate not realistically. Pumping money into circulation on the productive side creates debts, does not proportionately increase employment (even if this were desirable), and certainly raises prices. In its present form it is bound to fail. Mr. Roosevelt is finding this out.

During the war ration tickets were issued to everybody to enable people to share in the available food supply. War makes people think and act realistically. Why cannot money be issued to everybody to take unconsumed goods and services off the market? Money is a ticket.

I suggest, Sir, you consider the suggestion that a committee of engineers be set up to consider this simple proposal and its effect on prices and how they could be controlled.

To "give money for nothing" might be a ready quip to give in reply; but it is not giving money for nothing that is proposed. The proposition is to make money distribute our surplus wealth to people who want it.

Failure to solve this problem will mean the break up of our civilisation.

The Iron and Steel Institute.

No. II.

(Concluded from page 291, September 22nd.)

On the resumption of the meetings on Thursday morning the first business was the presentation and discussion of the Fifth Report on the Heterogeneity of Steel Ingots.

The report as a whole was presented by Dr. W. H. Hatfield (Chairman of the Committee); and Principal C. A. Edwards and Professor J. H. Andrew presented briefly the results of the work described in Sections V. and VI. respectively, with which they had been particularly concerned. This report occupies nearly 80 pages of the printed "Proceedings" of the Institute, and cannot be usefully abstracted. We give, therefore, the official summary of its contents :—

HETEROGENEITY OF STEEL INGOTS.

The present Report is divided into the following sections :—

Section I.—Introduction.
Section II.—Ingot Types.
Section III.—The Present Position of the Analytical Determination of Non-Metallic Impurities in Steel.
Section IV.—A Further Study of Steel Ingots.
Section V.—A Study of the Influence of Varying Oxygen and Carbon Content in Iron upon the Position of Blow-holes in Steel Ingots.
Section VI.—The Equilibrium of the System Fe_2P-FeS.
Section VII.—Estimation of the Time of Separation of the Ingot from the Mould.

A certain amount of confusion exists concerning the precise meaning of the various terms descriptive of steel other than fully killed. In Section II., therefore, an attempt has been made to define the terms in common use. It will, of course, be understood that each ingot type merges imperceptibly into the next, and just as no hard and fast line differentiates the various ingots, so no hard and fast definition can be laid down to describe them. Nor do the Committee aim at establishing such definitions, rather is it their intention to clarify the position by discussing in some detail the various types of ingot, and the various terms commonly employed to describe them.

Section III. of the Report contains a discussion of the various methods employed for the separation and determination of the quantity and analysis of the silicate inclusions in steel, and for the determination of the oxygen. It has for a long time been realised that this matter has rested on a not too reliable basis, and now, whilst finality has been by no means reached, certain progress has been made towards improving the accuracy of the determinations.

In Section IV. is described the full examination of three further ingots. The first is a small ingot of high-frequency steel which, whilst possessing no outstanding features, shows the ingot examined to be of uniformly good quality. The second is an ingot of low-carbon steel made by the acid Bessemer process, and may be compared with Example 59, illustrated in the Fourth Report, which was made by the basic Bessemer process. Finally, the third is an example of ingot iron which, owing to its unique method of manufacture, possesses many interesting features.

Section V. is a contribution by two independent investigators, who, working in co-operation with the Committee, have explored on an experimental scale a wide range of compositions with varying oxygen and carbon contents. It is of interest, incidentally, tq notice how in Plate VI. each of the commercial types of ingot illustrated in Section II. is simulated in its general features, whilst this investigation also shows clearly the relation of one ingot type to another.

Section VI., also the result of work carried out by independent investigators, is an exploration of the iron phosphide/iron-sulphide equilibrium, and is of considerable interest in considering the theoretical aspect of the mechanism producing heterogeneity in steel ingots.

Finally, Section VII. further extends the mathematical analysis of the cooling of steel ingots to cover the mechanism of the separation of the ingot from the mould.

DISCUSSION.

Mr. E. H. Saniter (Vice-president) welcomed the report as one of the best, if not the best, yet issued, and one which presented a more complete picture than had been possible hitherto. In the course of a somewhat detailed commentary on the report, he referred to Section V., dealing with the effect of carbon and oxygen on ingot structure, as being exceedingly interesting, and said the authors, by proceeding on a definite predetermined plan, had succeeded in making a series of ingots representing all the ingots of commerce and some that were not commercial but were occasionally made. The authors had proved that in an oxidised steel the content of carbon had a predominating influence on the nature and position of the blow holes. It would have been of great interest to have had more information as to the formation of blow holes by nitrogen and hydrogen. He referred to one particular ingot containing no carbon, but which showed a small number of large blow holes, and asked if they might be due to hydrogen and/or nitrogen. Again, it would be valuable to know the composition of the gas in the inner and outer row of blow holes in rimming steel.

With regard to the existence of CO_2 in the evolved gases, he pointed out that that could only occur in small quantities, if at all, for CO_2 could only exist in contact with molten steel if accompanied by a very large excess of CO. As to the solubility of CO in steel, he asked if it were possible that CO was more soluble in steel the higher the oxide content.

Discussing the reasons why blow holes occurred in certain places, and why, in wild steels, some rose and others sank, he drew attention to the importance of turbulence and viscosity. In one particular ingot, for instance, the blow holes were very near the skin and the evolution of gas must therefore have been immediate; but lack of turbulence resulted in increased viscosity, and that prevented the free escape of the gas and caused the ingot to rise. In another case he suggested that the great turbulence accompanied by less viscosity resulted in the gas bubbles being washed from the sides so that the formation of a solid skin was allowed. The rapid evolution of gas and consequent great turbulence was the cause of the hollow top or "box hat," as that condition of rapid evolution of gas continued when teeming was finished.

Finally, he suggested that further work on the question as to why sulphur and manganese did not segregate in molecular proportions during the setting of steel ingots would be appreciated.

Dr. W. Rosenhain said the authors had pursued their immense task of trying to discover in detail the mechanism of the differences of composition of structure existing in all types of steel ingots, mainly by the "natural history" method, *i.e.*, by examining a number of specimens with great care. That was useful work, but it was pleasing to know that they had also made a very excellent beginning with the "synthetic" method of attack. The scientific way, and the only really sound way, of attacking a very complex problem of that kind was to isolate some of the variables affecting the problem. That could not be done in practical steel making, but it had been done very successfully, to a limited although very useful extent, in Section V. of the Report, which dealt with the influence of varying oxygen and carbon content in iron upon the position of blow holes in steel ingots. He welcomed that section particularly, not so much because of the immediate importance and interest of the results, which were considerable, but because it indicated a new step forward.

A criticism he made was that perhaps the Committee had begun their labours just a little late in the steel-making process, and that they might consider the heterogeneity of liquid steel before it was put into ingots. They should consider the possibility that the composition of the liquid steel was by no means uniform by the time it was poured into the ingot, particularly, he imagined, in large masses of steel in which the reactions had taken place between slag and metal bulk at the interface, and where the opportunities for thorough mixing of the liquid had not been very favourable.

Discussing the work on ingots made in the small high-frequency furnace, he pointed out that when one teemed a small quantity of steel there was an appreciable amount of reaction with the air through which the liquid steel passed; he believed that that reaction was quite appreciable, even in large ingots, and it must represent quite an important feature in very small ones. So that the size of ingot to be used in that work was a matter for careful consideration. On the small scale probably the work could be more accurately controlled, but there were countervailing disadvantages in the large ratio of surface to mass of metal, and it might be desirable to conduct further work on a larger scale, perhaps ten or twenty times the scale adopted so far.

After an expression of appreciation of the work on the sulphide and phosphide equilibrium, Dr. Rosenhain took exception to a statement that, although it was known that that was a ternary system, it was much simpler to represent it as a binary. The attempt to represent ternary and quaternary systems as binary systems was a form of simplification which was apt to be misleading.

Dr. A. McCance (member of Council) complimented Professor Edwards on having evolved a reliable technique in the production of small samples of steel; metallurgists were on the track of a system of experimenting which would give results representative of steel works practice. Commenting further on Section V. of the report, he referred to cases in which, where sufficient aluminium had been added to reduce the oxide sound steel was obtained. That represented a definite advance because it had been considered in the past that the gas in solution in steel had a marked effect on producing blow holes. He believed strongly that in all cases the gas formed was a reaction product, and that if one removed the iron oxide and the carbon or reduced them below the equilibrium balance, no blow-hole was formed, and that none of the blow-holes were due to the solution of gas in the metal. He suggested that the work should be extended in order to arrive in a practical manner at the equilibrium constant of the iron oxide reaction. He had in mind a method whereby standard ingots were prepared, definite quantities of oxide added in the neighbourhood of the equilibrium for the carbon content concerned, and then definite amounts of aluminium added to find out what amount of aluminium was necessary or what amount of oxide it was necessary to reduce in order to obtain sound steel.

Mr. H. Spence Thomas (member of Council) was interested to know that some value was being given to turbulence in the manufacture of steel and its effect in giving greater homogeneity to the ingot. He also emphasised the importance of considering the quality of the steel in the mass before it was separated into small ingots, and wondered whether by that means we might be able to eliminate entirely the troubles of segregation in ingots.

Dr. C. H. Desch referred to some work which was begun whilst he was at Sheffield University, and had since been continued at the National Physical Laboratory, as the result of which a perfected iodine method could be used to determine the quantity of inclusions absolutely without loss. The Dickenson method or the electrolytic methods used in America and Sweden led to a certain loss of ferrous oxide, because the water brought about hydrolysis of the more basic substances. By an improvement of the iodine method, however, excluding water entirely, using a solution of carefully dried iodine in absolute alcohol, working in a nitrogen atmosphere, and filtering entirely in nitrogen through an ultra filter, it was possible to recover the whole of the inclusions without loss. They could be examined under the microscope and a subsequent analysis made. That was not likely to become available as a general works process, however, because it was rather too sensitive. Even breathing anywhere near the opening of the apparatus before it was closed would affect it, for the amount of moisture required to produce hydrolysis was extraordinarily minute. For organisations equipped with research laboratories, however, he believed it was likely to be the best of all methods. There was a plan in view for the co-operative comparisons of the different methods of oxygen determination in certain known steels, and before long practical methods of oxygen determination would be applied in any well-equipped steel laboratory.

Mr. N. D. Chopra suggested that homogeneity could be improved by the tilting of moulds and agitation of the molten metal. The three main causes of trouble in steel ingots, which causes it was desired to eliminate, were (1) the pipe or cavity; (2) occluded gases or blow-holes; (3) the crystalline condition. He submitted that all could be eliminated by mechanical methods, *i.e.*, by turbulence or agitation of the molten metal. Steel metallurgists had something to learn from non-ferrous metallurgy. In a works in south-east Germany it was found that by tilting the mould at 8 deg. the tensile strength of the steel produced was increased by 22 per cent. on the average; the elongation and reduction of area by over 40 per cent.; and the impact figure was more than three times that of steel which was cast under the same conditions but by the ordinary horizontal method.

Dr. Hatfield, in reply to the discussion, said that anyone who studied the report would be surprised to find how nearly the Committee had arrived, by the guidance of the evidence contained in the report, at almost technical perfection. It was true to say that solid ingots for forgings, as made in Sheffield and Glasgow, were remarkably good from the standpoint of a technical analysis of the degree of heterogeneity. But the problem was involved because in the heavy steel trade it was important to use the maximum proportion of ingots in the finished products. Thus there were two problems in one, for any solution involving a high scrap percentage in production would not be tolerated.

The Committee had indeed studied a perfect ingot. It was produced by pouring the steel in the mould at a temperature at which it froze almost spontaneously, and it weighed about 14 cwt. That could be done, he would not say "accidentally," but as a stunt. When producing a very large ingot, however, one could not pour at one particular temperature, but must cast over a range of temperature.

He gathered that Dr. Rosenhain had not deprecated the "natural history" method of investigation, which was the basis of all research. Anyone who was disclosing the facts of nature was essentially following the natural history method, and he considered that the Committee was right in basing its work largely on determining very thoroughly and completely the degree of heterogeneity of the various types of ingots now produced. Then they had built up from that.

"The Influence of Beryllium on Steel," by Mr. J. H. S. Dickenson and Dr. W. H. Hatfield, was the title of the next paper presented. We give the conclusions reached by the authors.

BERYLLIUM IN STEEL.

The results disclosed by this investigation indicate little or no prospect of the element beryllium becoming a useful addition to the group of metals used in the manufacture of special steels. The metal is extremely expensive, and is unlikely ever to become reasonably cheap, whilst its lightness and readiness to oxidise make the actual introduction into molten steel somewhat difficult and distinctly wasteful, even with the special method of addition employed in the present case.

As regards forging, the addition of 1 per cent. of beryllium tended to make some of the steels, particularly the 3½ per cent. nickel and the nickel-chromium steels, distinctly "stiffer" under the hammer, with an increased tendency to "burst," especially towards the top end, but it is probable that this would give rise to no serious manufacturing difficulty if the beryllium steels were required for use in engineering construction because of their desirable physical properties.

In this respect, however, the addition of beryllium has proved harmful rather than otherwise.

Apart from the hardness peak in the tempering range 400 deg. to 450 deg. Cent. and the associated brittleness and the liability to crack with rapid cooling, probably due to some pronounced volume change, the beryllium-bearing steels show throughout a marked liability to fragility, as evidenced by the impact test, which far outweighs the increase in tensile strength. In short, none of the steels containing beryllium has shown, with any treatment, the combination of high elastic limit and fatigue resistance with ductility and toughness, which is necessary in highly stressed engine parts. It was thought that the addition of beryllium might confer upon stainless steels of the 18 per cent. chromium, 8 per cent. nickel type, which are normally austenitic, an increased resistance to corrosion, but in this case also the results were definitely disadvantageous.

In conclusion, the authors would again repeat that this investigation was carried out with a limited objective, and neither time nor circumstances have so far permitted an extension of the programme, but they consider that certain of the facts disclosed, especially the temper-hardening at 500 deg. Cent., deserve much further investigation, and it is for this reason that they are presenting this paper.

DISCUSSION.

Dr. A. McCance, after remarking that the work described in the paper provided a good example of co-operation between firms engaged in the same line of business and two large research organisations, and that that example might, with advantage, be followed by other sections of the steel industry, thanked the authors for having overcome the difficulty of introducing beryllium into steel. He deprecated haste in forming an opinion as to whether or not beryllium had any future. Its price had been reduced as the commercial demand had increased, and there was no reason to think that it could not be carried lower if there was a larger demand. The actual physical properties of the steel in which it was used, however, did not look very promising. But beryllium, like all the lighter elements, depressed the change points very rapidly, with the result that the γ loop was closed with a very small percentage, something in the nature of 0·5 per cent. beryllium. With 1 per cent., therefore, it was outside that loop, and in a field where refinement of the grain structure could not take place by heat treatment alone. Brittleness in the 70 per cent. chromium irons had been overcome, and those alloys were obtained in a perfectly tough and useful form. Similarly, with beryllium, given a little further experience in the technique and manipulation, it might be possible to overcome the intense brittleness which it seemed to confer on steel. The important property was age-hardening, but he believed similar age-hardening properties could be obtained by the use of other elements at much less cost, although it would be interesting to study the effect of beryllium on high-speed steel, for the age-hardening range came within the tempering range of that steel, and it might increase the property of age hardness. So that while the results of the work were negative, so far as immediate application was concerned, the paper would be an important record for future investigators.

Dr. W. Rosenhain said he had several experimental melts of beryllium-iron alloys which showed remarkable properties, and he supported the warning uttered by Dr. McCance that the research should not be regarded as a final condemnation of beryllium as a possible element in connection with steel. The remarkable function which beryllium performed in nickel and copper was well known. The age-hardening effect of beryllium in copper, he believed, was greater than that of any other element in any other metal known, and in nickel it was of about the same order. Therefore, one might hope that if beryllium was rightly used, if the proper technique of heat treatment, and so on, was applied, it might be possible to obtain age-hardening effects in steel of a very marked character, taking into account that steel was initially harder and stronger than copper. Further investigation, on perhaps rather different lines from those indicated in the paper, would have to be made before the question as to the value of beryllium in steel could be determined.

Dr. Hatfield intimated that the 6 lb. of beryllium available to the authors for their experiments had cost £200, *i.e.*, over £30 per lb. So that he was afraid much time must elapse before the matter could become of great interest from the economic point of view.

Mr, Dickenson, replying to the discussion, said he was certain that neither Dr. McCance nor Dr. Rosenhain had supposed for a moment that the authors had left no loophole open for the future use of beryllium. The point was that the authors had concluded from their experiments that at the present time, under prevailing circumstances, there was no hope of getting a useful result with it which would approach justification of the expenditure involved. It was true that aluminium, at one time a museum specimen, now surrounded us in every direction, in quantity; but that hardly applied to any ore from which beryllium could be extracted. In short, he could not see at present any prospect of cheap beryllium.

The meeting then discussed a report by Dr. Marie Gayler on the "Alloys of Iron Research: Part XI., The Constitution of the Alloys of Iron and Manganese," of which a summary follows.

ALLOYS OF IRON AND MANGANESE.*

The constitution of the iron-manganese alloys has been determined by means of thermal, microscopical and X-ray examinations of alloys made from high-purity electrolytic iron and distilled manganese. In comparison with previous determinations, the position of the liquidus and solidus has been appreciably raised and the existence of a peritectic reaction between γ-iron and liquid to form γ-manganese has been confirmed.

The δ–γ iron transformation has been found to take place at 1504 deg. Cent. over a range of composition of 1 to 8 per cent. of manganese; γ-iron then separates directly from the liquid state, until at a temperature of 1270 deg. Cent. it reacts with the manganese-rich liquid to form a phase containing approximately 68 per cent. of γ-manganese. This peritectic reaction extends from 65 to 74 per cent. of manganese, after which the γ-manganese phase separates directly from the liquid on cooling.

The constitution in the solid state of iron-rich alloys has not yet been solved and has, therefore, not been included in the constitutional diagram submitted.

The changes in the solid state of manganese-rich alloys have been very carefully determined by means of the thermal, microscopical and X-ray analysis of a number of alloys. The γ-manganese phase is shown to decompose into γ-iron and β-manganese at a temperature of 1028 deg. Cent. over a range of composition of 64 to 72 per cent. of manganese, and similarly the β-manganese phase has been shown to decompose into γ-iron and α-manganese at 600 deg. Cent. over a range of composition of about 59 to 63 per cent. of manganese.

An Appendix by C. Wainwright, M.Sc., on the X-ray structure of manganese-rich alloys quenched from various temperatures is given.

DISCUSSION.

Dr. W. Rosenhain commented on the immense difficulty of the work described in the paper, and the endless patience with which those difficulties had been overcome; during many years' experience of research on alloys he had never known difficulties approaching those encountered in that particular work. Having emphasised the difficulty of the work, he continued, one might ask why it was done. For the benefit of those who were not enthusiasts he pointed out that there was a very good reason—that we should never understand our alloy steels thoroughly and gain full command of them until we understood their constitution and the changes occurring at different temperatures. So far we did not understand them sufficiently thoroughly. Many steel makers were in the habit of regarding alloy steels as iron-carbon alloys with something added; that, however, was not so. Current views on many of those alloys were at any rate imperfect and very misleading, and as the demands upon our special alloy steels increased in severity, the demand for accurate knowledge and the spade work which produced it, of which the paper provided a striking example, would increase. We must know the constitution of those alloys in the pure state before we could claim a knowledge of the ternary and quaternary systems; in many cases, contaminations influenced very definitely the resultant structure and constitutional change.

Dr. C. H. Desch, after confirming Dr. Rosenhain's remarks concerning the very great experimental difficulties and the great skill with which they had been overcome, said the iron side of the diagram had been held over at pressent because the data were not sufficiently complete; but that part of the diagram was exceptionally difficult, partly because there arose the same kind of difficulty that occurred in the iron-nickel series, *i.e.*, that of irreversibility; it was almost impossible to attain equilibrium. In that work one had to depend to a very large extent on X-ray data, because the multiple twinning was so elaborate that it was difficult to determine by microscope whether there were one or two phases. However, the work was being continued, for in order to gain knowledge of the alloy steels, metallurgists needed a knowledge of the fundamental binary diagrams.

A description of "A Coke-fired Re-heating Furnace" by Mr. F. Lloyd and Prof. R. V. Wheeler was then presented by Mr. F. Lloyd, who said that the coke-fired furnace described was an employers' contribution to the problem of smoke abatement.

A paper by Mr. J. E. Hurst on "Some Experiments on the Resistance to Heat of Nitrogen-hardened Cast Iron" was taken as read. There was no time for its discussion. It will be reprinted in a future issue.

The Institute of Metals.

IT was natural that the Institute of Metals should return to Birmingham, its birthplace, for its silver jubilee meeting, which was held last week under the presidency of Sir Henry Fowler. It was in 1908 that its first general meeting was held there, under the presidency of the late Sir William H. White, and the meeting this year was held in the same room, at the Central Technical College.

Again, it was natural and proper that on such an occasion some attention should be given to surveying the progress that has been made since the Institution's inception. Thus, the autumn lecture, which was delivered this year by Mr. W. R. Barclay, O.B.E. (a Vice-President of the Institute, and consulting chemist to the Mond Nickel Company, Ltd., of London), surveyed twenty-five years' progress in metallurgical plant in a masterly and interesting manner, and very many illustrations were shown of plants both in this country and abroad. A report of this lecture is printed on page 312. Another contribution on somewhat similar lines was an address by Dr. W. Rosenhain, on some steps in metallurgical progress between 1908 and 1933.

Invitations to visit a number of works were extended to and accepted by the Institute. The works visited included those of Earl, Bourne and Co., Ltd. (rolling and tube mills), the Austin Motor Company, Ltd., the General Electric Company, Ltd., I.C.I. Metals, Ltd., the London Aluminium Company, Ltd., W. and T. Avery, Ltd. (Soho Foundry), Joseph Lucas, Ltd. (lamps and accessories), Henry Wiggin and Co., Ltd. (nickel and its alloys), and the Birmingham Aluminium Company, Ltd.

From the social point of view the meeting was also memorable, including, as it did, municipal and university receptions, a luncheon, and visits to places of interest in the Midlands. The joint hosts at a luncheon on Tuesday, September 19th, were the Aluminium Hollow-ware Association, the Brass and Copper Tube Association, the Brazed Brass Tube Association, the Brass Wire Association, the Cased Tube Association, the Cold Rolled Brass and Copper Association, the Manufactured Copper Association, and the Nickel Silver Association.

A novel feature during the meeting was the reproduction of the first office of the Institute, in the Metallurgical Department of the University. This office was set up originally by Mr. Shaw Scott, who, together with the President and the Chairman of the Executive Committee, received there on Tuesday evening the surviving original members. This reception was quite informal, and the visitors had the opportunity of inspecting the earliest records of the Institute, including the original membership applications, and some photographs taken during the inaugural meeting in 1908. At that time the membership numbered about 200; it has now increased to 2200, and covers the whole world.

It was announced by the President during the course of the meeting that, although the Institute has not been affected from the points of view of membership and finance as much as some other bodies during the depression, a number of the original members had contributed to a special fund to promote the further progress of the Institute. It was proposed to use the money particularly in connection with publications. It had come to the knowledge of the Council, said the President, that certain members and firms in addition to the original members would like to contribute, and he intimated that the Council would welcome such contributions.

Dr. Barclay's lecture was the first official function of the meeting, and he delivered it on Monday evening, September 18th, in the Medical Lecture Theatre at the University of Birmingham, to an audience which almost taxed the quite considerable seating capacity of the theatre.

On Tuesday morning, after a civic welcome, Dr. Rosenhain presented his paper entitled "Some Steps in Metallurgical Progress, 1908–1933."

TWENTY-FIVE YEARS OF PROGRESS.

In presenting this paper Dr. Rosenhain said that the last twenty-five years had seen the battle for the recognition of scientific metallurgy fought and, he believed, won. Anyone who talked scientific metallurgy twenty-five years ago was looked upon as an academic enthusiast who was likely to have very little effect on metallurgical practice. There might be some who still thought in that way, but they were very few, and dare not raise their voices in public. Often he had heard young men regret that they had not lived thirty or fifty years ago, because then there was so much to be discovered, whereas now it was hard to find anything new because of the immense amount of work done already. He, too, had felt like that at one time—and every man who saturated himself with the knowledge already acquired was apt to think that it would have been easier to make advances if he had lived before it was discovered. But the facility for making fresh discoveries lay in the man much more than in the knowledge existing at the period in which he worked; and, indeed, if he appreciated rightly the knowledge already available it should give him openings more numerous and more readily available for attack to-day than ever before.

The paper was not submitted for discussion, inasmuch as it was in the nature of an address.

Two papers summarised below were then submitted together for discussion. They were "Properties of Some Temper-hardening Copper Alloys Containing Additions of Nickel and Aluminium," by Messrs. Brownsdon, Cook, and Miller, and "Precipitation-hardening Nickel-copper Alloys Containing Aluminium," by Messrs. Jones, Pfeil, and Griffiths.

TEMPER-HARDENING COPPER ALLOYS.

A study has been made of the effect of quenching and tempering on the properties of a number of copper alloys containing nickel and aluminium, and it has been found that when nickel, together with aluminium, are present in certain quantities and ratios, the hardness and other mechanical properties of the alloys are very considerably modified by the thermal treatment to which they are submitted. The alloys are softened by quenching from relatively high temperatures, and the quenched alloys, both in the soft and cold-worked conditions, harden considerably when re-heated or tempered to an intermediate temperature somewhat below the annealing temperature. For a few typical alloys the changes in hardness and mechanical properties that can be brought about by suitable heat treatment are given in some detail.

---

* Communication from the National Physical Laboratory, received June 7th, 1933.

NICKEL-COPPER ALLOYS.

The properties of nickel-copper-aluminium alloys with nickel contents from 10 to 45 per cent. and aluminium contents up to 4 per cent. have been investigated.

The relationships between composition and capacity for hardening by heat treatment have been studied by means of hardness tests on the heat-treated specimens. A study has also been made of the most suitable heat treatments to produce the soft condition, and the stability at elevated temperatures of a selection of the alloys in the precipitation-hardened condition. Finally, the mechanical properties have been determined of a group of alloys selected and prepared in accordance with the results of the preliminary experiments.

In certain cases the properties of the 20 per cent. nickel alloys were studied in greater detail than those at other nickel levels, but sufficient work has been carried out on alloys containing 10, 30, and 45 per cent. nickel to enable the properties of alloys at these levels and over a range of aluminium contents, and in various conditions of heat treatment, to be deduced.

DISCUSSION.

Mr. W. T. Griffiths, in presenting the second paper, took the opportunity to emphasise the difficulties with regard to nomenclature, as illustrated by the papers so far presented. In the first, Dr. Rosenhain had referred to " age-hardening " and " precipitation-hardening " ; in the second, reference was made to " temper-hardening " ; and in the third, " precipitation-hardening " was referred to. The time had arrived, therefore, to determine exactly how to describe this phenomenon, and the difficulty was to find words to describe the actual treatment. He and his co-authors had at first used the word " temper " when referring to the re-heating process. It was necessary, however, to describe that operation so that it would not be confused with the tempering treatment in steel, for some were in the habit of regarding that tempering as a softening rather than a hardening process. He suggested, therefore, that the Institute might be asked to give a ruling on the matter.

Professor D. Hanson (Vice-President) said the earlier heat-treated copper alloys mostly possessed rather low elastic limits—perhaps the beryllium alloy was an exception—but the particular alloys dealt with in the papers could be obtained, by simple heat treatment, in a condition in which they attained very considerable elastic limit ; that was a notable advance. That elastic limit might be still further improved by the application of a small amount of cold work, followed by still further heating, or perhaps by cold work before the tempering or re-heating process.

The authors gave a host of facts which it was difficult to correlate ; it was clear that they were rather groping in the dark, and he could not help feeling that it would be wrong to allow work of this kind to go too far without trying to find out just the constituents responsible for the phenomena produced, and what were the changes in solubility and so on which governed the heat treatment. He suggested that more attention could be paid to the properties—particularly the physical properties—produced in these alloys by varying the periods of tempering.

Dr. E. Vaders (Germany), discussing the paper by Messrs. Brownsdon, Cook, and Miller, said the authors' statement that the maximum aluminium content permissible in nickel-copper alloys was about 3 per cent. did not appear to be right in all cases. He had found that aluminium-nickel-copper alloys could easily be cold-rolled if, in the presence of 3 per cent. of aluminium, the nickel content was not more than 15–20 per cent. If the aluminium content rose to 4, 5, or even 6 per cent., the nickel content must be reduced to 10 per cent. or less. Aluminium-nickel-copper alloys containing about 10 per cent. nickel, 5 per cent. aluminium, and 85 per cent. copper, had a Brinell hardness of 70 when quenched. They could be rolled both in the cold and in the hot condition without difficulty.

He had found also that an addition of iron to aluminium-nickel-copper alloys might be useful, investigations having been carried out with iron contents from 5 to 15 per cent. It was found, for instance, that an alloy containing 10 per cent. nickel, 5 per cent. aluminium, and 85 per cent. copper showed marked temper-hardening effects if 10 per cent. iron were added, whereas the alloy free from iron possessed no hardening tendencies.

The solubility of aluminium in nickel-copper alloys seemed advantageously influenced by the iron. When quenching alloys containing iron, more aluminium was held in solid solution than with alloys free from iron. In consequence, the mechanical properties of those alloys were much higher than of the ternary aluminium-nickel-copper alloys. Certain iron-aluminium-nickel-copper alloys had a tensile strength of about 77 tons per square inch, and elongation of 3–4 per cent. The alloys were not badly influenced by the iron in respect of rolling properties. He had cold-rolled an alloy with 10 per cent. iron from 6 mm. to 0·5 mm. thick without annealing. The elongation of that alloy in the soft, *i.e.*, the quenched, condition was about 50 per cent., and in other alloys it was more than 60 per cent.

From the results obtained it appeared that the nickel content and the aluminium content were dependent on each other, inasmuch as a low nickel content entailed a high aluminium content, whereas, on the other hand, a high nickel content entailed a lower addition of aluminium.

With regard to a statement in the paper by Messrs. Jones, Pfeil, and Griffiths, that with increasing aluminium content a higher temperature was necessary to give the best precipitation-hardening, he said that was only the case in respect of alloys free from iron and having low nickel content. The aluminium-nickel-copper alloys containing iron were of interest not only for their high tensile strength, but also their magnetic properties and good resistance to heat. An addition of only 5–10 per cent. iron was sufficient to render the alloys strongly magnetic. The permeability, &c., had not yet been investigated. It might be that those properties would render the alloys useful for electrical purposes, the more so as they were absolutely rustproof. With regard to heat resistance, certain alloys in that range were not seriously attacked, even if heated to 900 deg. Cent. for three hours ; they remained bright and smooth.

Mr. A. L. Archbutt (Member of Council), Mr. E. H. Bucknall, Mr. W. F. S. Hubbard, and Mr. A. J. Murphy also spoke.

Dr. Cook, replying to Professor Hanson, said the authors realised that the experiments on the improvement of the elastic limit by a combination of heat treatment and cold working were only preliminary, and they felt that the work could usefully be extended in that direction ; they were optimistic about obtaining even better values than those recorded in their paper.

With regard to the effect of time and temperature, he said the experiments were not directed entirely to finding out the minimum time in which to accomplish the maximum hardening. It might be—though there was no evidence from the results to suggest it—that a longer ageing period at lower temperatures would give better information on the qualities generally.

To Dr. Vaders he pointed out that, as stated in the paper, when the aluminium content exceeded about 3 per cent., they had experienced difficulties in cold fabrication of the alloys. They knew that for hot work the aluminium content could be raised to 5 per cent. or so. In that connection he drew attention to a statement in the other paper that, in the preparation of the alloys, ingots which were ¾in. thick after softening by quenching were cold-rolled to ¼in.—a reduction of 66 per cent. In view of his experience, however, he suggested that that was extraordinarily difficult to accomplish, especially in alloys with an aluminium content exceeding, say, 4 per cent. Some of the tables showed that those alloys, even in the quenched, *i.e.*, the softest possible condition, had a Brinell hardness in excess of 200.

Mr. Griffiths, replying on behalf of Mr. Jones, Mr. Pfeil and himself, said that while they had been able to give a certain amount of information on the alloys studied, they had still much to learn, especially in regard to the reasons why. They had ideas, but not definite proof. The fact was that the problem opened out by work such as that was enormous. Small amounts of constituents which they had not yet considered might affect the results considerably. Their purpose was to place on record some of the results obtained during the past five or six years, to stimulate other workers. The task of finding the reasons why might be considered perhaps by the academic and university laboratories.

In reply to Dr. Cook, he said that he and his collaborators had not attempted cold-rolling the alloys with high aluminium content, but had hot-rolled them.

A paper on " Wear in the Polishing of Plated and Other Surfaces," by Dr. O. F. Hudson, was then presented.

POLISHING OF PLATED SURFACES.

A series of tests was made in the laboratory of the British Non-Ferrous Metals Research Association to determine the comparative rates of wear of plates and other metal specimens under conditions of polishing as distinct from abrasion. The apparatus used is described, and the results obtained with the following materials are given, using magnesia on wet parchment as the polishing medium :—Pure platinum, pure palladium, platinum plating on brass, palladium plating (" soft," " hard," and burnished) on brass, nickel plating (" soft " and " hard ") on brass, silver plating, and brass (60 : 40).

Considered as loss of thickness, the rate of wear of the palladium-plated specimens was found to be greater than that of the platinum-plated specimens, but considered as loss of weight, the wear of the palladium coatings was slightly less than that of the platinum coatings ; whilst the precious metal coatings generally were more resistant than the same metals in massive form. Of the three types of palladium-plating, that in the " soft " condition showed the greatest wear, but the differences were not great ; there was little difference in the rates of wear of the two kinds of nickel-plating. No definite or consistent relationship between hardness and rate of wear in polishing was revealed in these tests.

DISCUSSION.

Dr. W. Rosenhain (Past-President) said he was particularly interested in the author's use of magnesia as a polishing agent, for he himself had introduced it for metallographic purposes about 1904, and its use had been adopted widely since. He had first used it because he had been anxious to obtain polished surfaces of specimens consisting of two metals—iron and copper—in juxtaposition, and the difficulty was that the ordinary polishing reagents, such as rouge and chromium oxide, dragged one metal over the other to such an extent that the boundary line between the two was difficult to trace. Magnesia dragged less than any other polishing material, and his suggested explanation for its behaviour was that it was not a true polishing agent, but was a very fine-grained abrasive. Polishing was connected with the solubility of the polishing agent in the metal that was polished, and he imagined that magnesia had very little of that property. Possibly the ratio of wear obtained by Dr. Hudson would be rather different if rouge were used instead of magnesia. Again, abrasion was partly a chemical action, and oxidation played a very considerable part. Therefore, when comparing metals such as platinum, on the one hand, and nickel or even silver, on the other hand, one was not comparing them under identical conditions, unless one excluded the action of oxygen. Possibly, the failure to discriminate between hard and soft nickel was due to their being chemically attacked at very much the same rate. One could not eliminate abrasion from polishing experiments, and, if there were no abrasion, he could not see how there could be loss of weight.

Mr. H. N. Bassett (Chief Chemist, Egyptian State Railways), also said he could not understand how there could have been loss of weight without abrasion. He suggested that there was a very fruitful field in the investigation of the preparation of polished surfaces with different abrasives under precisely similar conditions, particularly in different atmospheres.

Dr. Hudson, in his reply, said the paper was simply a record of some experiments with one particular polishing material. It was probably correct that abrasion of a sort did occur ; but there was a distinction between a process such as the final polishing and the abrasion arising in the use of a coarse abrasive as a preliminary operation before final polishing.

The meeting then adjourned until Wednesday.

When the meeting was resumed on Wednesday, September 20th, the first paper to be taken was one entitled " Further Observations on the Distribution of Porosity in Aluminium and Copper Ingots, with Some Notes on Inverse Segregation," and the author was Mr. N. P. Allen.

ALUMINIUM AND COPPER INGOTS.

The author reports that three copper ingots and four aluminium alloy ingots cast in a specially tapered mould were examined. In all cases the distribution of porosity followed the probable form of the isotherms in the cooling mass, and was much influenced by the mould taper. The type of microstructure also had an influence on the distribution of porosity, the nature of which he discusses. The inverse segregation of two aluminium-copper alloy ingots was found to be closely related to their porosity.

DISCUSSION.

Mr. H. Sutton said that at the Royal Aircraft Establishment, Farnborough, large aluminium alloy ingots for forgings were cast with a hot-top or dozzle lined with sand, which resulted in good feeding, and appeared generally beneficial. Inverse segregation could not be avoided in that way, however. Bohner had found that " topping-up " ingots during freezing had no important effect from a practical point of view on inverse segregation, but his results on aluminium alloys indicated that both inverse and normal forms of segregation could be minimised by the use of very high or very low rates of cooling of the molten alloys. That indication was in good agreement with the view that inverse segregation was the result of volume changes.

Mr. R. Genders, whilst agreeing substantially with Mr. Allen's conclusions, pointed out that certain variables of the casting process had been neglected altogether, so that some of the generalisations made in the paper were subject to modification. He discussed the theory of inverse segregation. Commenting on a copper mould illustrated in the paper, where the thickness of the wall at the bottom was increased substantially in order to encourage progressive solidification from the bottom upwards, he said that although those conditions might encourage it, the encouragement was never sufficient to have any appreciable effect.

Dr. W. Rosenhain remarked that unfortunately the facts quoted did not tally with the facts found frequently in the production of ingots of various sizes under other conditions. He was unable to understand how the author had arrived at some of his conclusions, and it was difficult to reconcile the view as to the outward flow of rich inter-dendritic liquid with the suggested existence of negative pressure inside the ingot. He doubted very much that a negative pressure ever existed, except very transitorally. He had seen many examples in which there was no doubt that the method of filling the mould had made a great difference.

Dr. F. Johnson welcomed a reference in the paper to an ingot of copper which had shown a considerable rise in the mould after being melted in a highly reducing atmosphere ; that result disposed of the argument that electrolytic copper could not be over-poled. Discussing inverse segregation, he referred to an instance within his own experience concerning a very small ingot of Admiralty gun-metal with low tin content in the outer shell and high tin content in the interior, there being almost complete absence of the low melting point interdendritic constituent in the outer shell and a preponderance of it in the centre. That was a very clear case of inverse segregation, but was not in line with Mr. Allen's explanation of the internal pressure forcing a low melting point constituent into the interdendritic spaces.

Dr. A. G. C. Gwyer called Mr. Allen's attention to the recent work of Masing and Scheuer, who regarded inverse segregation as being due not so much to contraction processes as to the growth of the primary crystals forcing the nuclei apart and intersticial flow occurring in the spaces.

Mr. Allen, replying to the discussion, said he did not think there was really much doubt that exudations on the surface of a casting must be caused by gas. In a comment on Dr. Rosenhain's remarks concerning the pressure inside the ingot, he suggested that Dr. Rosenhain had neglected the possibility that there might be variations of pressure in the liquid metal from side to centre of the ingot.

A "Note on the Green Patina on Copper: Examples from Elan Valley (Wales) and Dundalk (Ireland)," by Dr. W. H. J. Vernon, was then presented and discussed.

It was followed by one on "Magnesium Alloy Protection by Selenium and Other Coating Processes," by Dr. Bengough and Mr. Whitby. They observe that small losses of weight of Elektron alloy AZM (sheet) resulting from corrosion by immersion in or spraying with sea water have been found to be associated with serious losses of elongation. Visual inspection did not suggest the extent of the damage, which occurred even when the alloy was protected by chemical coatings and paint.

The last paper read and discussed was entitled "Experiments in Wire Drawing: Part III.—Annealing of H.C. Copper Wires Drawn to Varying Degrees of Hardness," and was by W. E. Alkins and W. Cartwright. The authors' summary runs as follows :—

EXPERIMENTS IN WIRE DRAWING.

Silver-free h.c. copper of good quality (99·95 per cent. copper) was drawn into nominal No. 12 S.W.G. (0·104in.) wire, intermediate annealing being introduced in such a way as to furnish eleven coils of wire varying in breaking load from 399 lb. to 544 lb., and with reductions of area after annealing of from 36 to 97 per cent. Samples were annealed for periods of one-half, 1, 2, 6, 12, and 24 hours, at 130 deg., 155 deg., 170 deg., 180 deg., 205 deg., 230 deg., and 280 deg. Cent., and for half an hour at 330 deg. 450 deg., 650 deg., 750 deg., and 850 deg. Cent. Mean breaking loads after each heat treatment, frequently and carefully checked, are published.

It is found that the annealing behaviour depends not so much on the original tensile strength of the wire as on the amount of reduction by cold work which it has undergone. To express this in a form convenient for diagrammatic representation, the "work ratio"—diameter at intermediate annealing divided by final diameter—is used.

The more lightly drawn wires show an appreciable increase in strength after annealing at low temperatures. They retain their strength at temperatures up to, say, 250 deg. Cent., very much better than the harder wires. The latter begin to soften at temperatures little above 100 deg. Cent., and the rate at which strength is lost increases with increasing cold work. The hardest wires all show a definite decrease in breaking load after storage for two years at room temperature; the more lightly drawn wires show no change. This apparent differentiation is again suggested by the breaking load/temperature curves from 450 deg. to 850 deg. Cent.: the lightly drawn wires decrease slightly but steadily in strength with rising temperature, but all the harder wires without exception have higher breaking loads after annealing at 750 deg. Cent. and again at 850 deg. Cent. than they have after heating at 650 deg. Cent.

After all heat treatments of sufficient severity to effect more or less "complete" annealing, the breaking load is lower the less the amount of cold work done on the wire, and it increases steadily with increasing cold drawing until the three most severely drawn wires of all are reached, when there are fairly definite indications of a decrease in the strength of the fully annealed wire.

The importance of these facts from the point of view of any theoretical discussion of annealing phenomena, and conversely in their bearing on the whole problem of hardening by cold work, is evident.

DISCUSSION.

Mr. E. H. Bucknall, after a brief reference to earlier work, including some carried out by the Non-Ferrous Metals Research Association on locomotive stay rods, in which marked stiffening of cold-worked materials was effected in low-temperature annealing, said it would appear that with hard-drawn wires there was at the higher temperatures a hardening, possibly of the same type as that of the lightly drawn materials at the low temperatures. He also suggested that it would be enlightening to investigate the effect of annealing for periods shorter than half an hour at elevated temperatures, as well as the effect of annealing for longer periods at lower temperatures.

Professor D. Hanson (Vice-president) suggested that the authors might enhance the value of the paper by attempting some estimate of the crystal size in their wires, for it might provide a complete explanation of their results. They had summarised their results in the statement that "the greater the amount of cold work done on the material, the lower is the temperature at which it begins to lose its work hardness and the greater the rate of loss at any temperature, but the higher is the tensile strength characteristic of the fully annealed material."

Dr. H. O'Neill asked if the authors could give the values for reduction of area for tensile test pieces. Discussing the method of preparing the copper, he said it was first cold drawn to decreasing diameters, then annealed, and finally cold drawn. He gathered that the annealing, at 650 deg. Cent., of copper which had been reduced various amounts meant that the breaking load would differ in the different specimens, so that the specimens were not necessarily in the same condition when cold drawing was begun. What would be the objection to hot working the original bolt down to the various sizes, then annealing to remove working strains, and then finally cold drawing?

Discussing a reference to increased breaking load and decreased ductility, he mentioned some X-ray examinations of cold-rolled copper annealed at 130 deg. Cent. to produce slight stiffening. The copper was cold rolled about 50 per cent., and showed distinct preferred orientation. After heating at 130 deg. Cent., the only change detected in the X-ray spectra was a slight decrease in the intensity of the preferred orientation. If that were substantiated it would suggest that the grain size was more "messed up," and he suspected that perhaps within the distorted grains tiny new grains were forming, and that there was a mist of these new grains throughout the mass, which meant more boundary and greater stiffness or decreased ductility. This might be the reason for the rise of breaking load reported by the authors.

Dr. H. W. Brownsdon disagreed with a statement in the paper that, in the light of the results obtained, the tensile strength of a "completely" annealed high-conductivity copper wire was emphatically not a characteristic property of the material. Copper, he said, was a most subtle material, and minute quantities of impurities seriously affected the mechanical and other properties, and he did not think the authors' work justified the use of the word "emphatically." With regard to their statement that they had used a "silver-free" high-conductivity wire, he believed there was only one brand which satisfied that designation; the majority of high-conductivity coppers within his experience contained silver, and he suggested that the authors' results should be clearly related to the one sample they had used as a special sample.

Mr. J. S. G. Primrose, referring to the increase of breaking load—which really meant the maximum and not the theoretical breaking load—said he had found that low-temperature annealing released the stress in the skin of lightly drawn copper and other wires, which stress was due to the light drawing, and had not penetrated to the centre. Thus the true stress on the material was recorded in the breaking load.

Mr. H. J. Miller commented upon the slight increase in strengths which the authors had obtained by annealing at very high temperatures, and the different range of results obtained, depending on the previous amount of cold work. It was notable that in one table of results the wires subjected to the least amount of cold work showed continued softening as the annealing temperature was raised, whereas those subjected to a greater amount of cold work showed definite increase of strength with the highest annealing temperatures. He suggested that these results were associated with the development of directional properties consequent upon differential grain growth, since the factors involved—excessive cold work and a high annealing temperature—were known to be responsible for the development of directional properties. Unfortunately, wires could only be tested in one direction; it would have been better if the authors had worked on strip.

Mr. Cartwright, replying to the discussion, said the authors had attempted to tackle the problem of crystal size, but the greatest difficulty was that they could not use for wires the usual method of counting crystals. In reply to Mr. O'Neill, he said that they had no figures for reduction of areas, but hoped to publish a short note in the near future giving elongations. As to the preparation of the specimens, the trouble was that they could not hope to hot-roll down to the small sizes used. In reply to Dr. Brownsdon, he said the analyses made by the authors were not spectroscopic, but were made by the ordinary analytical method, and, judging by that method, the material was silver-free. They were glad to obtain so pure a copper, because they desired to investigate pure copper first, so that later they could make additions to it, and would know that the difference in the results obtained would be due to the additions. Finally, he assured Mr. Miller that they would take the earliest opportunity to study directional properties.

SIXTY YEARS AGO.

THE decay of the British Association was the somewhat startling subject with which we dealt in a leading article in our issue of October 3rd, 1873. The Association had been founded about forty years previously, at a meeting held at York. A body of quiet, unobtrusive men of science and research had formed it with the object of making up the leeway in science which this country had suffered during the preceding half century, as a consequence of the prolonged periods of interruption in our communications with the Continent of Europe caused by the wars of those days. The aims of the founders were clearly and wisely defined, and year after year the Association gathered strength and influence in spite of the early opposition to it expressed by *The Times* and numerous theologians and sectarians. Among its councillors and workers were many brilliant men—Brewster, Dalton, Forbes, Herschel, Faraday, Murchison, Baden Powell, George Rennie, and others of world-wide reputation. By 1873 all these pioneers had gone to their rest, and we could see no successors worthy to take their place. Decrepitude and decay had, we said, first begun to appear round about 1850. From that date onwards, so we alleged, the Association had shown an ever-increasing tendency to fall away from its early ideals. Of the chief elements constituting the decay, we gave first place to the composition of the Council. It was, we said, no longer composed of men renowned for their scientific labours, but included persons who had secured election to it by an abuse of patronage or because of their wealth, their rank, or their social or political influence. The management of the Association had become lax and misguided. In the Geographical Section annual attempts, we said, were made to provide a "draw" by lionising some notable individual. At Brighton in 1872 it had been Stanley, or, as we put it, "the flashy agent of a 'cute American newspaper which had sent him after 'our illustrious traveller' who would not himself communicate his whereabouts in Africa." At the Bradford meeting of 1873 it had been Sir Samuel Baker, fresh from having, according to his own account, extinguished slavery in Africa for ever. Neither of these men, we said, was scientific, nor had they pursued scientific work in the undertakings by which they had acquired popular fame. In the Mechanical Section opportunities for advertising trade objects had been widely seized by men with no pretensions to scientific research. The addresses of the Sectional Presidents had on the average become clap-trap utterances designed for the speaker's personal glorification. The evening discourses, with rare exceptions, had descended to the level of "mere flashy dissertations on things in general." Instead of promoting science, the Association had been tempted to make itself an organ for influencing the Government to pass laws which some of the members believed to be necessary or for extracting funds from the public to promote some crotchety object. It was meddling with public matters of various sorts, from education to total abstinence, with which it had no concern, and had opened its doors to cranks and humbugs to whom a hearing ought never to have been granted. . . . We cannot believe that all that we said on this occasion was meant to be taken seriously. That very year Joule was President of the Association, although ill-health had compelled him to relinquish the office before the annual meeting. That year, too, Clerk Maxwell delivered an evening discourse on "Molecules," which even to-day can be read with profit and pleasure. Sir William Siemens discussed "Fuel" and its utilisation, and we thought sufficient of his lecture to reprint five columns of it. In the Mechanical Section Osborne Reynolds had papers on the theory of propellers and guns, and Mr. (Sir) Wm. White lectured on "Channel Steamships." Balfour Stewart discussed "Ethereal Friction." Barlow, Berthon, James Napier and others whose names are still remembered to-day also contributed to the proceedings.

BRITISH STANDARDS INSTITUTION.

All British Standard Specifications can be obtained from the Publications Department of the Institution at 28, Victoria-street, London, S.W.1. The price of each specification is 2s. 2d. post free, unless otherwise stated.

TARS FOR ROAD PURPOSES.

No. 76—1930. An important modification has recently been made in connection with the instrument to be used for the measurement of the viscosity of Tar No. 2 contained in the B.S. Specification No. 76—1930.

Experimental research has confirmed the practicability of adopting the B.R.T.A. viscometer, already standardised for the measurement of the viscosities of Tars Nos. 1 and 3, for Tar No. 2 also, in place of the Hutchinson tar tester, and accordingly, the B.R.T.A. instrument has now been adopted as the standard for Tar No. 2. A Corrigendum slip—reference No. C.D. (P W) 950—setting out the necessary alterations to the published specification, may be obtained gratis on application.

DEFINITIONS AND SYMBOLS FOR WELDING AND CUTTING.

No. 499—1933. The rapid development of the art of welding, and especially of fusion welding, has introduced a technique and vocabulary which is all its own. The preparation of a standard list of terms applicable to the art, defining what each means, is clearly a matter of prime importance.

The Standard Nomenclature, Definitions, and Symbols for Welding and Cutting, which has just been issued by the British Standards Institution, has been prepared to meet this need.

Terms are, for ease of reference, grouped under five main sections as follows :—

Section I.—Definitions of general terms applicable to all forms of welding and also including cutting terms.

Section II.—Definitions of methods and joints relating to forge welding.

Section III.—Definitions of methods, terms, and joints relating to pressure welding.

Section IV.—Definitions of methods, terms, and joints relating to fusion welding.

Section V.—Definitions of terms relating to welding and cutting equipment and supplies.

A complete alphabetical index is included so that the definition number of any term can be easily found. Where desirable, in order to prevent the possibility of misunderstanding, illustrations and diagrams have been inserted.

A system of indicating welds on engineering drawings has been prepared in which a capital letter is used to indicate the general form of joint, such as "B" or "T" for a butt joint and tee joint respectively, and a combination of numbers and suffix letters is appended to indicate the particular form of weld. There is also a statement of the dimensions to be given.

Details of the working of the scheme are given in full, together with an explanatory chart; an illustration of each form of fusion welded joint is included and a weld symbol given to it.

It is held to be of particular importance that those entering the industry should, from the beginning of their training, use the definitions, terms and symbols now standardised.

As far as the symbols for indicating welds are concerned, the standard will become an essential adjunct to B.S.S. No. 308—1927, Engineering Drawing Office Practice, in which the usual symbols used on engineering drawings are standardised.

The price of the publication is 2s. 3d. post free.

Railway and Road Matters.

The recent scarcity of water in various parts of the country has drawn attention to the fact that the Great Western Railway pumps some 12,000,000 gallons of water from the Severn Tunnel which is discharged into that river.

What is known as motor trolley maintenance, which was originated on the Great Western and is now also used on the North-Eastern area of the L. and N.E.R., saves the provision of flagmen on single lines and more quickly conveys men and material to and from a job. The *Great Western Railway Magazine* for September reports that it is now under test for use on double lines.

The Railway Staff Census, just issued as a Stationery Office publication, covers the week ended March 11th, 1933. It shows that the number of railway servants on that date was 566,300, as compared with 597,971 in March, 1932, a decrease of 31,671, or 5·30 per cent. The more noteworthy reductions are: Engine drivers, 33,389 to 32,171; firemen, 31,144 to 29,832; goods guards, 13,842 to 12,906; labourers, 24,922 to 20,567; engine-shed staff, 9453 to 8480; permanent way men, 57,766 to 54,626; shopmen, 92,206 to 84,792; signalmen, 26,299 to 25,537. In the ancillary business the staff on the docks has been reduced from 12,783 to 11,552.

The name "London Passenger Transport Board," having been found to be too long for general use, it has officially been abbreviated to "London Transport." While that name will be used to describe the undertakings of the London Passenger Transport Board as a whole, the names of each of the forms of transport will continue in use. "General" will still appear on the sides of the omnibuses, and, similarly, Underground Railways, Green Line Coaches, Tramways, and Trolleybuses will still describe the various services. The full title, "London Passenger Transport Board," will also continue to be used where—as on the sides of the road vehicles—it is a legal requirement.

Since November, 1931, each system engineer, *i.e.*, divisional engineer, on the South African Railways has kept a record of the permanent way material on hand at each district depôt so as to ensure that no new material shall be ordered that can be obtained by transfer from one point to another. As a result, the value of the stock on hand has been reduced from £287,528 in 1929 to £118,272 in 1931, and the expenditure on material for maintenance purposes from £371,284 to £169,405. All the lines were inspected during the year 1931–32, particular attention being devoted to the state of the track materials. The inspections disclosed that the permanent way has never been in better condition.

In the last quarterly returns of railway accidents a fatal accident reported upon by Mr. Scott Main related to a gang of thirty-two men who were engaged in re-sleepering. The work, which was in the London area, had to be done at night, and the men assembled at the station concerned at 12.30 a.m. One man, however, went to an adjoining station, and, later, his dead body was found by the side of the line. The point we wish to bring out is that Mr. Main remarked that the ganger failed to have a roll call, otherwise the missing man's absence would have been noticed. The advisability, he adds, of taking this course when dealing with a considerable number of men on similar work is, he thinks, desirable.

The present week sees the centenary of an event which was mentioned in The Engineer of November 28th, 1924, in article XXII. of our series "One Hundred Years of British Railways." Mentioning the Dundee and Newtyle Railway, sanctioned in 1826, we said that when the line was opened in December, 1831, the three inclined planes were worked by stationary engines and the level portions by horses. On September 30th, 1833, two locomotives, the "Earl of Airlie" and the "Lord Wharncliffe," were put into service, and on March 2nd, 1834, the "Trotter" was added. All were of what is now known as the 0–2–4 type, *i.e.*, with a trailing bogie, and were the first locomotives in Great Britain to have that feature.

Remarkable speed records were established by the L.M.S. Railway between Euston and Coventry and *vice versâ* on Tuesday, September 19th, when two special trains were run in each direction for the accommodation of guests visiting the Humber-Hillman-Commer motor works at Coventry. The fastest run of all was made by "Flyer No. 2," returning from Coventry to London in the evening, when the 93½ miles from Coventry to a signal stop just outside Euston station were covered in 74 min. 20 sec., at an average speed of 75½ miles an hour start-to-stop. Including the signal stop of two minutes' duration, Euston was reached in the unprecedented time of 79 min. from Coventry. The maximum speed attained on this run was 92 m.p.h. at Castlethorpe, while 90 m.p.h. was touched before Weedon, near Watford, and again at Wembley. The train of seven coaches weighed just over 200 tons, and was hauled by the L.M.S. "Royal Scot" class engine "Comet," Driver B. A. Marchant and Fireman W. Aldridge, of the Camden (London) depôt.

The death, on September 18th, of Mr. David Bain, who was the carriage and wagon superintendent of the Midland Railway from 1901 to 1919, recalls the pioneer work done by that company in the provision of comfortable rolling stock. That work was begun by T. G. Clayton—who came from the Great Western—when new trains were necessary for the Anglo-Scottish service on the opening, in May, 1876, of the Settle and Carlisle line. During the brief interval between Mr. Clayton's retirement and Mr. Bain's appointment, Mr. T. P. Osborne was in charge. Mr. Bain maintained the good work done in those twenty-five years, but it was in detail rather than in principles. One innovation has done excellent work; that is, the shock-absorbing buffer to avoid telescoping. When Mr. John Holden, of the Great Western, retired, Mr. Bain succeeded him as chairman of the Committee for the Standardisation of Privately Owned Wagons. During the war he was Controller of Timber Supplies, and soon after the Armistice he intimated his wish to retire, being then over the age limit. He was succeeded by Mr. R. W. Reid, whose death, ten years later, will always be a pathetic memory.

Notes and Memoranda.

An electric motor of 1000 horse-power, recently built by the Westinghouse Company of America, which runs at 514 revolutions per minute, can be brought to a stop from full speed in 3½ revolutions. The rotor weighs over 3 tons.

An electrical machine for sorting postal orders has been devised for use in the Post Office. There are forty-one different denominations of postal orders, and, to adapt them for sorting in the new machines, newly issued orders are punctured in different positions. The fact that 214,000,000 postal orders were paid last year indicates that the machines will eliminate much manual work.

A paper by Dr. E. Mallett, issued by the Institution of Electrical Engineers, describes a wattmeter depending for its action on the use of two thermionic valves and a direct-current measuring instrument. Three forms of instrument are described, the first suitable for measuring the powers used in ordinary power work, and the second and third for measuring the small powers used in communication work.

Electrical engineers, states the *General Electric Review*, have used kilovolts, kilowatts, and kilovolt-amperès regularly, but have not felt the need for kilo-amperès. Yet if engineers investigating lightning keep on, it should not be long before kiloampères become commonplace. A measurement in Pennsylvania early this summer indicated a current of 60,000 ampères in a flash of lightning. A simple magnetic instrument developed in the General Electric Company's Laboratory at Schenectady was used in obtaining the measurement.

It is claimed by R. Treje and Professor C. Benedicks, of the Metallurgical Institute of Stockholm, that they have worked out a rational method for the electrolytic extraction of slag from iron and carbon steel, the residue being uncontaminated by iron hydroxide or basic iron salts. Electrolysis is performed in a vessel divided in two by a diaphragm. The iron specimen—surrounded by a collodion bag, carried by a floating wooden ring, for collecting the slag—forms the anode in a bromide solution containing sodium citrate. The cathode consists of a copper plate in $CuSO_4$ solution.

The contract for the design and construction of the new McDonald Observatory on Mount Locke in South-Western Texas, containing the second largest telescope in the world, has been awarded to the Warner and Swasey Company, Cleveland. The project will cost approximately 325,000 dollars, and will require 2½ years to complete. The telescope will be owned by the University of Texas and operated by the University of Chicago under a co-operative arrangement. The telescope is to be of the reflector type, approximately 26ft. long, with a main mirror 80in. in diameter, weighing 5000 lb. It will be housed in a three-storey observatory, 71ft. high, surmounted by a dome weighing 115 tons.

Speaking at the British Association, Major Church said that the present position in television is that pictures far better than those using mechanical reconstituting devices are now obtainable with cathode-ray receiving apparatus, but the Geneva Convention made absolutely no provision for the proper expansion and development of television in the broadcast band of wave lengths. The alternative to violating the international agreements affecting broadcast channel widths or developing an entirely new radio technique was to have local areas served by ultra-short wave transmitters, but many practical difficulties remained to be overcome before that was possible. Experimental short-wave transmissions of high quality, however, had already begun in London from the Crystal Palace towers.

Although exports of electrical goods and apparatus during August show an advance of £105,369 over the figures for the corresponding month of 1932, this improvement is more than offset by a decline from £270,516 to £156,288 in electrical machinery exports. A drop of £24,542 in imports was due principally to decreases of £16,975 and £16,738 respectively in the purchases of telegraph and telephone apparatus and unenumerated electrical machinery. Compared with July the value of exports was £15,637 lower, again on account of decreased shipments of electrical machinery. This decline would have been more severe but for increased activity in the telegraph and telephone section. Except in the case of incandescent lamps, imports generally exceeded the August, 1932, values, and were £64,903 higher at £255,294.

A synchronous motor operating efficiently at variable speeds by means of a new type vacuum tube control was recently demonstrated in the General Electric Company's test laboratories at Schenectady, U.S.A. The new control, a development by Dr. E. F. W. Alexanderson, is expected to be useful in many fields for operating A.C. motors at various speeds with remote control, an example being electric ship propulsion. With the turbine running at full speed constantly, the speed of the propeller motors can be varied by changing the frequency of the current fed to them through the vacuum tube control. Instead of the captain communicating orders to the engine-room for a change of speed, the new apparatus makes it possible for him to regulate the speed of the driving motors directly from the bridge. The motor demonstrated was 400 H.P. and the efficiency of the frequency converter 98½ per cent.

There is a description in the *Bulletin* of the General Electric Company of a new device which ensures the safety of passengers from being struck by sliding doors, whether they are operated by electric or pneumatic means. A beam of light is focused across the lift car entrance on to a photo cell. Passengers entering or leaving the lift must of necessity interrupt this light beam. The effect of breaking the beam ensures either that the doors remain in the open position or, if they have started to close, that they will open again. All the time the beam of light is broken it is impossible to close the doors to the lift. The whole of the necessary apparatus can be fitted on the lift car and thus only one unit per lift is necessary. A unit comprises an adjustable projector arranged to focus light on a self-contained photo cell set which operates relays in the motor room connected with the power doors. Structural alteration to standard types of lifts is not involved.

Miscellanea.

It is proposed to put up a gasmaking plant at Harbin.

It is officially announced that the blast-furnace of the South African State steel works at Pretoria will be blown in next January, according to schedule.

After being shut down for 2½ years, the Thurcroft by-product plant, Yorkshire, is again to start up. It is expected that the preparation work will take about two months.

The Corporation of Middlesbrough is contemplating the abandonment of some of its electric tramways, but has not yet decided as to whether the substitute shall be trolley omnibuses or motor omnibuses.

It is announced that a large aeroplane, capable of carrying 128 passengers, as well as the pilots and other members of the crew, has recently been constructed in Kharkov, and is undergoing a series of test flights.

It is proposed to re-open the Chalainor coal mine of the Chinese Eastern Railway, which was badly damaged during the military operations at the time of the Sino-Soviet conflict. The cost of the works is estimated at a million gold roubles.

The latest estimates of the probable average duration of the period of open navigation from the newly opened port of Churchill, Hudson's Bay, Canada, out into the Atlantic, give the dates of August 1st and October 20th as the opening and closing days.

It is understood that the War Department is considering tenders for a new vessel to be used for towing floating targets for artillery practice. The requirements call for a very special type of ship of the tug class, and a group of modifications and improvements will be embodied in the new vessel.

It is announced from Leningrad that the Soviet shipping department has begun the preparation of a scheme for the construction of the largest electrical icebreaker in the world, for service on the great northern sea route. Work has also been commenced on two smaller electrical ice-breakers, one of 4500 tons and the other of 1200 tons. All the three ships are to be ready by 1935.

After having been advocated for many years, a start is about to be made on enlarging the Dortmund–Ems Canal, and a preliminary sum of 6,000,000 marks has been set aside by the Reich Ministry of Finance for the execution of canal works. The Rhine allows the transport of ore and coal in large barges up to 2000 tons, while the Dortmund–Ems Canal can only take barges up to 750 tons.

Plans have been drafted for construction of a new railway station to accommodate the headquarters of the Shanghai-Nanking and Shanghai-Hangchow Railway Administration in place of the North Station, which was partially destroyed by Japanese bombardment during the Sino-Japanese hostilities in Shanghai. The site measures 10,000ft. by 3000ft., and the cost of the works is put at about £1,000,000.

One of the effects of a decision of the Canadian Government, according to the *Financial Times*, of Montreal, will be to permit the Royal Canadian Mint at Ottawa to extend its refining facilities to United States gold as well as to Canadian gold. Furthermore, the bulk of the United States annual production of gold, amounting to 40,000,000 dollars in value, will be smelted and refined in Canada. Smelting will be carried out in northern Ontario, and at Trail, B.C., but gold will be refined to the purer state at the Ottawa Mint.

High-frequency radio telephones have, says the *Engineering News-Record*, been installed at headquarters, field offices, and boats on the San Francisco-Oakland bridge work to improve communication facilities over the scattered operations now starting on the project. Both the engineering organisation and the two foundation contractors on the main channel work will make use of the system. The radio phones will eliminate countless trips by messengers on boats to remote pier locations, and are estimated to effect direct saving in time as well as provide closer contact in the working organisations.

Under an order recently circulated, the French Minister of Public Works reminds engineers of the Ponts et Chausées, of Mines, and of his Department that they render themselves liable to dismissal if, without having first obtained special permission from his Ministry, they carry out surveys for or give advice to private concerns. The Minister adds that where the regulations in this respect have been overlooked, and officials have not obtained the permission of the Ministry to carry out private projects or surveys, the Chief Officers should take immediate steps to stop this irregularity by acquainting him with all the particulars.

A project is under consideration, says the *Engineering and Contract Record*, of Canada, for the development of natural gas and oil resources in Manitoba and for the piping of the gas to the City of Winnipeg for domestic and heating uses. The site of the development is about 95 miles from Winnipeg, and it is understood that the promoters are meeting with excellent success in financing their undertaking. The cost of the pipe line is estimated at around 600,000 dollars, while the plant complete with power-house, refinery, and other necessary units, would involve an expenditure of 10,000,000 dollars or more. This development, should it proceed, will greatly stimulate business in Winnipeg and Manitoba generally.

The fifth blast-furnace to be blown in this year, and the hundred and seventh at present working in the Soviet Union, recently started production at the new Azov Steel Works in Mariupol, a port on the Azov Sea, in South-Eastern Ukraine. The Azov Steel Works have been designed for an annual production of 924,000 tons of pig iron. They will be equipped, in the first stage, with four blast-furnaces, thirty-one tilting open hearths, rolling mill equipment for the manufacture of rails, and a coke and chemical plant with an annual capacity of 1,300,000 tons. Among other divisions it will also include a large sintering and flotation plant that will prepare the ore to be brought from Kerch, a town on the other side of the Azov Sea.

QUALITY AND PRICE.

WELL over a year ago the Federation of British Industries, and through it the British Standards Institution, received from the British Chamber of Commerce in the Argentine Republic a letter touching upon a subject of great importance to the export trade of British engineering firms. In that letter, which has not been made public, it was said that the quality of British engineering products was so high, and their price in consequence so great, that competition with rival manufacturers who were content with lower standards was very difficult. Commenting on the general terms of this complaint in our issue of June 3rd, 1932, we pointed out that whilst it was of old standing and had been frequently made by responsible people, it had never been seriously debated by British engineers. We expressed our conviction that in view of the manner of presentation the matter could no longer be shelved, but that it demanded, and we felt sure would receive, the most careful attention. Furthermore, we hoped that in due time the B.S.I. would publish the reply which it sent to Buenos Aires. That reply was despatched on July 10th last, and by the permission of the Institution we print it in full to-day. Some surprise will perhaps be felt at the long time it took to prepare. It must, however, be remembered that numerous bodies had to be consulted before a generally acceptable reply could be drawn up, and that the machinery of a great organisation depending upon the voluntary help of a great many people cannot easily be accelerated. The interval between question and answer, over sixteen months, is certainly long, but we may at any rate take it that its length indicates that the document now sent represents the considered view and opinions of the mass of British engineers.

The first fact that must strike the reader of the opening paragraphs of the letter is that the same attitude which has always been taken by British industry when faced with this problem is now adopted. Briefly, it comes to this, that whilst the British Standards Institution appreciates the spirit in which it has been approached by the Chamber of Commerce in Buenos Aires, it has found no sufficient arguments why it should depart from the standards which, with the general agreement of engineers, it has set up. It repeats the well-worn argument "that the reputation of British machinery has been built up on quality and durability, and that these characteristics have in the past proved effective from the point of view of sales." It even carries the war into the enemy's camp, so to speak, by affirming that the evidence collected "would appear to indicate that on the whole there would be very much to be gained by purchasers making use of British Standards and practices." It is impossible not to feel that whatever force there may be in these arguments is destroyed by the refusal, according to the Buenos Aires Chamber of Commerce, of the people of the Argentine to pay for the British standards of excellence. However proud we, as a nation, may be of them, however certain that other nations would benefit by following our example, we cannot get over the fact that our power of competition on price is weakened by an adherence to these standards. But the merits of British standards is not the sole argument advanced in their support. There is yet another old one which the B.S.I. employs. It reminds the Chamber of Commerce of "the economic difficulties of accommodating modern manufacturing methods to the very diverse requirements of numerous markets." Of the justness of that contention there can be no manner of doubt. Everyone knows that the essence of standardisation is the crystallisation of certain selected forms, and that departure from those forms involves increased manufacturing costs in any factory that has adopted them. But, again, it is manifestly fruitless to present those forms on a market which resolutely refuses to accept them, and which can obtain from other sources forms or qualities which it prefers. That is the quandary in which the British manufacturer is placed. By the conviction that his standards are the best possible compromises, and through the economic conditions which are imposed by their adoption, he places himself in the position, according to the British Chamber of Commerce in Buenos Aires, that he cannot sell his goods to the Argentine purchaser. No amount of argument can get round that uncomfortable fact. The B.S.I. has taken the greatest pains to reply in detail to the cases presented by the Chamber of Commerce, but none of the arguments it advances in support of British practice are likely to prevail appreciably with Argentine buyers, who, no doubt, will continue to purchase cheaper or lighter, or more heavily stressed, or less efficient machinery if it suits their pockets and their conditions so to do. Indeed, we hope more from the few promises of the B.S.I. to review certain of its specifications and by its efforts to get international agreement on certain matters than from its arguments in support of British practice.

Whilst there exists in this country no other body to which this great question, as far as it affects engineering, could have been referred, it must have been foreseen that the B.S.I. could scarcely give any answer different from that which it has given. The purpose to which it is now devoted, if not precisely that for which it was established, is the maintenance and extension of the principles of standardisation. Moreover, it is its boast, on good foundations, that the standards it prescribes are sanctioned and approved by the best engineering talent and experience in the country. It admits that in preparing its specifications "the conditions at home have played a dominant part, yet it can give as its honest opinion that on the whole foreign purchasers would be well advised to accept British standards." Holding these views, it would have been strange indeed if the B.S.I. had not replied to Buenos Aires in the terms set forth on another page. But it is difficult to escape the conviction that the B.S.I. found the complaints of the Chamber of Commerce so inimical to all its principles that it could not review them with complete sympathy. Hence, save for the distant hopes which arise from the prospects of international agreement on a few issues and the promise to reconsider certain specifications, the position remains exactly as it was, and foreign competitors will continue to prevail against British engineers in the Argentine as much as ever. We are still faced by the fact that the standards which are considered desirable by this country are higher than the standards desired by other countries. Therein lies the problem that remains to be solved: how to secure the advantages of standardisation whilst giving the foreigner the quality, the design, and the price that appeal to him. The B.S.I. does, it will be observed, suggest a possible course. Whilst rejecting the introduction into its specifications of different grades of quality for home and export, it invites the Chamber of Commerce to strengthen the Local Committee of the Institution and to transmit to London criticisms of existing specifications. "The question," it continues, "would then be one as to whether the proposed modifications would be generally acceptable for all markets, or whether they could only be applicable to the Argentine market, and might *have to be issued under the ægis of our Argentine Local Committee.*" The suggestion of differential selection conveyed by the words which we have italicised opens possibilities which may, if they prove practicable, have fruitful results. It is satisfactory to know, as reported in the second letter of the B.S.I., that in South Africa "the standard set by British Standard Specifications is a definite asset rather than a disadvantage in securing business in that market," and it is reasonable to hope that South America may in time be brought to the same frame of mind. But in the meanwhile something has to be done to retain our position in that market. Once lost, it will be difficult to regain, and some concession to its requirements may be a wiser policy than unbending adherence to specifications which do not appeal to it.

Power Cultivating Machinery.

THE satisfactory use of motor cultivating machinery does not depend upon any generally applied principle of agriculture, except the economic necessity of decreasing costs and increasing profits. The manner in which builders of tractors and other power machinery for tillage purposes approached the problem was revealed for many years at the annual official demonstrations held in France, and the International Exhibition of machines organised by the State Comité Central de Culture Mécanique at Arpajon last week, when the machines were shown in operation on a field, indicated that agricultural engineers are finding a solution of the problem in a selection of tractor types that differ essentially from those which in the past were demonstrated at these gatherings. The idea that influenced the researches of engineers at the beginning of the movement in favour of the tractor was that the farmer must necessarily use power machinery for cultivation in order to put more land under crops and reduce proportionately his costs. Tractors were being employed on the big cornfields in North America, and during the war many hundreds of such machines were brought over from the United States. Subsequently, they were purchased by the State and distributed all over France and in the African Colonies. They were not a success. They, nevertheless, demonstrated the possibility, and even the necessity, of adopting power mechanism for ploughing at a time when the country had to increase its production of cereals under conditions of labour scarcity. The years that followed were a period of experiment, when makers exercised their mechanical ingenuity with little knowledge of what farmers needed, and agriculturists, not being mechanics, could render little assistance. They watched with interest these efforts to help them, though refusing to purchase machines without a definite guarantee of saving in cost. The slump that followed the period of agricultural prosperity left the tractor industry in a serious condition. In those countries that merely aim at producing sufficient cereals for home needs the farmer does not generally want to increase the area of ploughed land. The cultivating machine must therefore allow more profit to be made out of every acre tilled. Now that the engineer has emerged from the trial-and-error period, there is an elimination of types of machines that do not fulfil these conditions. Improvements in others added interest to the French demonstrations to which we have just alluded.

The problem that confronts the tractor builder is complicated by the varied conditions under which agriculture is carried on in different countries. It is largely a question of population and labour. At the present time, farmers in Central Europe find it cheaper to employ men than to use machines, and in North Africa native agriculturists, who were induced by enterprising salesmen to purchase tractors, now condemn them as the cause of their trouble, although the real reason is the unprofitable prices of grain, and, more especially, the lack of mechanical ability to use the machines economically and keep them in good order. The problem has, therefore, entered upon a new phase, now that an extensive, and in many cases unfortunate, experience has enabled tractor builders to find a solution with every promise of success. Progress in France has been retarded by an objection on the part of farmers to use petrol, which is expensive and entails risks that add to their insurance charges. The State sought to impose the use of a "national fuel," incorporating a percentage of alcohol, but this mixture failed, and the evolution towards the use of heavy oils and the introduction of the high-speed solid injection oil engine was therefore inevitable. At the French demonstrations there was not a single heavy tractor running on petrol. All the machines had settled down to a somewhat uniform type, and as during the past two or three years heavy oil engined tractors have been selling, despite the crisis in the agricultural industry, there is every indication that the machine evolved for cultivation and general farm purposes has started upon a new period of practical and progressive development. The troubles incidental to wheel adhesion are being tackled by the low-pressure pneumatic tire with some promise of success. It should presumably economise fuel consumption relatively to the work done and conduce to a lessened cost of upkeep, whilst it appeals to the user by removing restrictions imposed on steel-tired tractors on the road. To this extent, therefore, the outlook for the agricultural tractor is distinctly hopeful. In a country like France, which is being entirely electrified, for electricity is distributed throughout all the rural districts, it might be supposed that electrical tillage machines would enter largely into agricultural practice. If they have failed to make more progress it is not for lack of enterprise. Yet of firms which have entered into this experimental field only two remain. An extensive employment of electrical ploughing machines depends upon reduction of cost. The farmer in France, as in this country, is not satisfied with the electrical distribution. He finds that the price of current is too high, that the conditions imposed upon him are too onerous, and that the electricity companies cannot afford to install mains that will carry sufficient load to enable a number of farmers in a district to plough at the same time during a few days of the year. Hence electrical cultivation is practically at a standstill. Then there is the class of small farmers who constitute the enormous majority of machinery users in the country. Here, again, it was hoped that an almost unlimited field would be opened up to the engineer who could provide a type of light tillage machine at low cost. An international committee was constituted, with headquarters at Lausanne, to investigate the whole problem of a small general purpose tractor, and trials and competitions were organised for a machine that could be assembled with standard parts to be stocked in all agricultural centres. Nothing appears to have come of these efforts to create an international standardised type of cheap tractor for small farmers. The problem, therefore, remains to be dealt with by individual makers, some of whom achieve encouraging results. At the French demonstrations the motor tillage implements shown, generally fitted with small air-cooled petrol engines, have a practical application, and this branch of light mechanical tillage offers a wide scope to the engineer because the required conditions can be met economically in many different ways.

The main conclusion arrived at after an inspection of the machines at the French gathering is that the agricultural tractor, both for medium and light cultivation, has developed in a way that will give a progressive activity to the tractor industry as soon as agricultural conditions tend to become normal. For the heavier class of machines the universal adoption of the high-speed heavy oil engine is but another indication of the position which the compression ignition engine is clearly destined to take in all classes of haulage and transport.

25 Years' Progress in Metallurgical Plant.*

By W. R. BARCLAY, Vice-President.

I.—DEVELOPMENTS IN MELTING AND CASTING EQUIPMENT.

As a convenient starting point for a review of this section, we may recall for a moment the type of casting equipment in common use in the early years of the present century. The great majority of the non-ferrous manufacturing works in this country were equipped only with crucible furnaces of the pit type—for the most part coke-fired. A limited use was made of oil or gas fuel for metals and alloys of high melting points, such as nickel and its richer alloys, but the furnaces used even for this type of product were essentially of the conventional crucible type. The main development prior to the period now being considered was the provision of forced draught and mechanical tilting. So far at least as non-ferrous metals are concerned, electric furnaces were non-existent. At that period the only furnaces which, to the works' metallurgist, held out any substantial promise of successful operation were the Héroult and the Kjellin types. The former is an arc furnace, the latter an induction furnace, and the proposals for electric melting of non-ferrous metals most favoured at that time were those embodying the "resistance" principle. To make use of the ordinary crucible and surround it by graphite or other refractory resistance elements electrically heated was a natural suggestion arising out of conventional practice. Investigation of the possibilities of this type of furnace, however, quickly revealed not only the practical difficulties, but also the serious problem of securing anything like economic operating costs. It was really the advent of the Ajax-Wyatt low-frequency induction furnace which made the electric melting of brass and copper alloys generally a commercial success and led to the adoption of electric melting on a wide scale.

During the last ten years progress has been exceedingly rapid. In the non-ferrous industries both the arc type and the induction type of electric furnace may be said to be definitely established. The resistance type of furnace has also been developed with considerable success in the melting of aluminium and aluminium-rich alloys. For copper and its chief alloys, induction furnaces of the Ajax-Wyatt and Russ designs are most generally favoured. For higher temperature metals, such as nickel and its alloys, the arc furnace of the Héroult type is most popular. The latter type of furnace design has been appreciably varied by different makers both in Europe and America, but in essential principle all such furnaces depend on radiation heating by the electric arc.

From a technical point of view, the most interesting advance of the latter part of our period is the introduction and development of the "high-frequency" induction furnace, due in the main to Northrup in the United States. This furnace is a modern development, made possible only by advances in the science of electrical engineering, and as a melting proposition, at least in theory, presents extremely attractive features to the metallurgist, since it provides the possibility of melting under conditions ideally suitable for the exclusion of extraneous impurities. It must be admitted, however, that the high-frequency furnace is more suitable for high than for low-temperature alloys, and consequently its adoption in the non-ferrous metals industry has been somewhat slow. The high-frequency furnace as at present designed is, unfortunately, a somewhat costly proposition in capital expenditure, and it cannot be claimed that it is appreciably more economical in power consumption than the arc furnace. These facts have undoubtedly retarded its progress in the non-ferrous industries. Up to the present time its main use in this field lies in the production of high-purity nickel-containing alloys.

Before leaving the subject of metal-melting equipment, perhaps I may be allowed for a moment to deal with a question which I have been repeatedly asked during the last few years—namely, how does the cost of electric melting in this country compare with that of coke, gas, or oil-fired crucible practice so far as non-ferrous metals are concerned? The difficulty in replying to this question is one relating largely to the scale of production. It is unquestionable that with furnace linings of modern composition and construction, and electric energy at anything like a reasonable price, electric melting is decidedly more economical than coke-fired crucible melting, if the quantity dealt with is sufficient to keep an electric installation reasonably fully employed. For production on a small scale, and particularly where a large number of individual and special alloys is made, the coke-fired crucible furnace still holds its own in this country.

Moulds.—The production of liquid metal, from whatever form of furnace, is, of course, only one stage in the production of ingots. A further radical factor in casting equipment is the ingot mould. In this type of equipment again considerable developments have been witnessed, the most important of which is undoubtedly the advent of the water-cooled mould. This development, like many others in modern metallurgical practice, was under discussion long before it became a practical proposition. The chief credit for its industrial evolution must be given to Otto Junker in Germany, and Erichsen in Sweden. The designs adopted by both makers are based essentially upon the use of a mould lining of copper or some other suitable alloy, surrounded by a steel jacket through which provision is made for a continuous flow of water, hot or cold. The lining of the Junker mould has always been of copper. Erichsen, on the other hand, developed the idea of using a nickel-iron alloy of the Invar type, and claims thereby certain improvements in results in solidity of ingot casting.

The advantages and disadvantages of the two types of mould are somewhat controversial and need not be considered here. What must be said is that the advent of the water-cooled mould marks a decisive stage of progress towards the industrial production of sounder ingots. Amongst the advantages of the water-cooled mould is the possibility of obtaining uniform temperatures throughout practically the whole period of solidification. It must, however, be pointed out emphatically that the use of such a mould does not remove the need for strict attention to the other factors essential to the production of sound ingots, particularly the "feeding of pipe."

Apart from the possibility of obtaining more accurate temperature control, the principal advantage secured by the water-cooled mould is economy in casting costs; this is without doubt very considerable. In the use of the older type of cast ingot mould, the wastage, particularly where fairly high temperature alloys were being produced, was extremely serious, and was no small factor in the cost of ingot production. Some very remarkable results illustrating this point were obtained in the earlier days of experimental work with such moulds when I was engaged in their development for the casting of nickel-brasses. With the older type of mould it was no uncommon thing for a set of moulds to deteriorate after three weeks' work so seriously as to necessitate either removal from service altogether, or complete reconditioning. In contrast to this, one of the earliest water-cooled moulds that I installed was in continuous service for more than eighteen months, and even at the end of this period the surface of the inner lining was in a much better condition than the best of our cast iron moulds.

The introduction of the water-cooled mould is, however, by no means the only improvement in ingot casting practice which the last quarter of a century has witnessed, and, although only brief reference can be made, I must not omit mention of such improvements as the introduction of the Durville system of casting. This is the outcome of a study of the technological factors involved in the pouring of molten metal into ingot moulds. As you are aware, the Durville principle is that of tilting the mould as well as the molten metal container during the operation of pouring metal into the mould, thus producing cast ingots with only the minimum of disturbance in the liquid metal immediately before and during solidification. There can be no doubt that this type of mould and the improvements in casting technique thus developed by the work of Genders and his colleagues at Woolwich, under the auspices of the British Non-Ferrous Metals Research Association, have made possible the casting on an industrial scale of several metals and alloys which would otherwise present almost insurmountable difficulties.

II.—ROLLING MILL MACHINERY.

The development of rolling mill machinery, whilst perhaps not so fundamental in nature as that which has occurred in casting equipment, has, nevertheless, been important and perhaps even more impressive, particularly in the production of sheet and strip metal. Twenty-five years ago the general equipment of practically all non-ferrous rolling mills in this country consisted of what are termed "train rolls," *i.e.*, a series of two-high mills of various sizes driven by one prime mover (steam or electric) and linked up either in series or parallel by reduction gearing. In many cases an entire mill equipment of fifteen to twenty pairs of rolls was driven from one prime mover by the aid of a large and heavy fly-wheel. Several such mills driven by the old "Watt type" of beam engine still remain in this country.

It must be admitted that these mills were usually run at a low cost per unit of power in the prime mover, but their disadvantages increased seriously as demands became more diverse and erratic, as in the case of modern industry. Since 1908, and particularly since the outbreak of the war, "train mills" have repeatedly given place to mills "individually driven" by electric power. The chief advantage of such individually driven mills is that if a considerable quantity of sheet or strip metal of similar widths and gauges is in demand, such mills can be run independently and continuously without regard to other mills or subsidiary plant, the product of which may temporarily not be required. The advent of the individually driven mill has led to a revolution in rolling mill design.

The non-ferrous rolling mill of a generation ago consisted of rolls and housings and wobblers and pinions almost literally thrown together, with little regard either to precision in construction or economy in power consumption. A modern individually driven mill, whether of the two-high or the more complex type, is, on the other hand, a precision machine, designed and built with all the skill and attention to detail required in a high-grade machine tool. As a consequence, the rolling process has become much more scientific, the percentage of reduction during passes more uniform and regular (with obvious advantages to uniformity in cold working), and gauging is more accurate, both in cross section and longitudinally.

A specially important feature of the modern precision cold-rolling mill is the adoption of hardened nickel-chromium steel rolls with water-cooling devices. Such rolls have a scleroscope hardness of from 95 to 100 and possess remarkably good surfaces. Their outstanding advantages to the metal roller are:—

(*a*) The improved surface obtainable on cold-rolled sheet or strip metal;

---

* Twelfth Autumn Lecture to the Institute of Metals, delivered September 18th, 1933. Abridged.

(*b*) The retention of uniformity of camber and greatly reduced liability to distortion during heavy service.

Both of these factors are particularly important in finishing operations.

During the last few years considerable publicity has been given to the more complex individually driven mills of the four-high and six-high (cluster) type. Such mills should certainly find an important place in any review of rolling development in our industry. In some respects they represent a further improvement even on the precision two-high mill, particularly when for any reason, metallurgical or economic, appreciable percentage reductions per pass are required. The answer to the question as to whether the installation of four-high or six-high mills is advisable depends entirely on conditions, and on more than one occasion I have in certain circumstances advised the erection of a two-high rather than a four-high mill. The more complex mill, with its backing-up rolls and roller bearing equipment, is undoubtedly economical in power, and with properly cambered working rolls is exceedingly accurate in product, and capable of giving big reductions with uniformity of gauge, but its advantages cannot be either demonstrated or experienced unless the type of output required is suitable. These complex mills are essentially "mass production" machines, requiring quantity and standardisation of product in order to realise their full possibilities. The industry as a whole is, unfortunately, not yet "standardised," and in meeting the varied demands which come to the manufacturer of rolled metal products in non-ferrous metals to-day, it is often more economic to continue to use the two-high mills rather than incur the increased capital cost of the four-high or cluster mill. At the same time, I hold strongly that the introduction of these latter mills is a further step forward in rolling mill design, and it will, I believe, pave the way in the future to still greater improvements.

A further development of cold rolling mills is the Steckel mill, which, although not as yet at all widely adopted in the non-ferrous industries, deserves at least a brief mention. This mill is a distinct departure from conventional rolling mill design, both from an engineering and metallurgical point of view. The metallurgist regards cold rolling as a process of cold working, and is therefore able to appreciate the essential difference between the type of cold working effected by the ordinary rolling mill operations and the type effected by "drawing" such as is carried out in the production of rods, wire, and tubes, in which the crystal grains of metal are drawn one over the other and elongated more or less uniformly, instead of being compressed in one direction only. The fundamental principle of the Steckel mill is the subjecting of strip or sheet metal to the latter type of cold working rather than to the former. The strip to be cold rolled is passed through small working rolls which have an action corresponding rather to that of dies through which metal is drawn than to that of rolls subjected to pressure. The metal is fed into these working rolls from drums which are electrically driven and capable of rapid reversal. The working rolls of the Steckel mill are exceptionally small (2in. to 2·5in. in diameter), and have consequently to be supported by backing-up rolls. The drive is almost entirely by tension on the strip itself, and the small rolls thus constitute in effect a frictionless rotary die. It is claimed for this mill that by its use considerably greater percentage reductions can be obtained without intermediate annealing than by any other method, and those of you who are aware of the greater percentage reductions usually obtainable in the operations of "drawing" as compared with those of "rolling," will appreciate the possibility of such a result.

Hot Rolling.

During recent years the importance of hot rolling has been more widely appreciated, and it is being more and more generally adopted as the result of our increased knowledge of the possibilities of hot working in the production of a large proportion of industrial non-ferrous alloys. Not many years ago it was considered that very few such alloys could be hot rolled, 60 : 40 brass being an outstanding exception. To-day in modern plants even alloys of the nickel-brass type may be, and are being, hot rolled.

In the earlier part of the period under review very little change occurred in the mills put down for hot-working non-ferrous metals. They were almost invariably two-high mills of the purely conventional type. Since the war, however, a change of a kind not dissimilar to that which has occurred in cold-rolling plant has occurred also in hot-rolling mills, and practically every hot-rolling mill put down since the period at the end of the war has been of the individually driven type, with a number of detailed improvements which have raised the standard of efficiency and accuracy.

The majority of the mills recently erected for the hot rolling of non-ferrous metals are probably of the three-high type, but several important modern installations, particularly for the hot rolling of copper and brass, consist of two-high mills, although these depart in many ways from the older designs. I wish particularly to direct attention to the factors making for greater precision, *e.g.*, the development of machine-cut helical gears; the greater width of pinions and their improved mechanical design, with provision for more efficient lubrication; the mechanising of screw-down gear, with the adoption of fine adjustments; and the remarkable improvement in coupling spindles. Not the least of the recent advances in detail of construction of the modern rolling mill is the provision of automatic lubrication, which effects considerable economies in power consumption while at the same time lengthening the life of wearing parts.

Before leaving the subject of rolling mills I must make brief reference to the latest of all developments in this field. I refer to what is known as the Hazelett rolling process, on which considerable experimental work is now being carried out in the United States of America. While this cannot be regarded as a development brought to completion within the period under review, I feel justified in referring to it, since the experimental work which has led up to it certainly belongs to this period. It must, I am sure, have occurred often to observers of the processes of casting and hot rolling that considerable loss of heat energy, as well as delay in processing, occurs in the cooling down of ingots and their re-heating for rolling purposes. The Hazelett process seeks to remedy this. Instead of using the normal ingot mould, molten metal is poured between water-cooled rollers in such a way that immediately the metal begins to solidify the rollers can be set into operation and the process of reduction to sheet be begun almost instantaneously.

III.—Rod and Wire-drawing Plant.

In this field new developments of machinery have scarcely been so far-reaching as in the other fields already surveyed. Cold-drawing benches for rods and tubes remain to-day much as they were twenty-five years ago, except for modification in engineering details such as direct electrically driven worm gearing. The improvements in rod and tube production during the period have been by no means negligible, but such improvements have resulted from factors other than the process of cold-drawing. The improvements arise mainly from the increased use now being made of extrusion processes.

In wire-drawing machinery, however, developments have been very considerable, and are in some degree comparable with those in cold rolling, particularly in regard to the greater precision and efficiency of modern machines. The production of rod and wire involves, of course, the operations of both rolling and drawing, and in both these sections improvements in the design of equipment have been effected. The modern rod and wire rolling mill, while not widely departing in fundamental principle from earlier designs, has been so greatly improved in detail of construction that it can be not unfairly compared with the improvement in the two-high rolling mill.

The improvements effected in wire-drawing machinery are considerable and important. Exigencies of time and space prevent me from dealing with these at such length as I would like, and I must confine myself to generalities rather than to details. I am glad to be able to say, however, that British engineers have been active in this field, and some of the wire-drawing machines produced by British manufacturers compare very favourably indeed with those on the Continent. I am more happy to say this here since it was scarcely possible to say it twenty-five years ago.

It is interesting to note that these improvements have not been primarily in connection with details of design, but have arisen from what may be termed "the greater realisation by engineers of what is required by metallurgists." The essential principle in wire-drawing is to obtain absolute uniformity of cold work throughout the cross section of the wire being drawn. The requirements, therefore, are obviously that the wire shall enter the die at exactly the proper angle, in order to meet the bevel of the die with mathematical accuracy round the surface to be drawn. In the past this point has not been by any means universally realised by designers and manufacturers of wire-drawing machinery, and there can be no doubt that improvements in this respect constitute the most important modifications of the modern machine.

On the other hand, detailed improvements such as that of effecting a large number of reductions in one continuous series of drafts has also led to no inconsiderable increase in efficiency and economy.

Although not coming strictly under the head of wire-drawing machinery, I think that it is necessary to refer briefly to the development of dies during this period, and particularly to composition dies of the "tungsten-carbide" type. These have to some extent replaced both diamond dies and steel dies, and their use has certainly led to great improvements in the life of dies, better service, and more accurate gauge. The bugbear of the wire-drawer is, of course, the fault known as "pulling out," that is to say, the change in section effected in the hole of the die by irregular wear. The very much harder surface obtainable from these composition dies as compared with the older steel dies is a considerable factor in the progress made in this direction.

IV.—Auxiliary Equipment, Annealing Furnaces, and General.

In this final section of my review of development I propose to deal briefly with a few auxiliary items of non-ferrous metal mill equipment, and also with the subject of annealing furnaces.

Improvements of importance, both in principle and detail, have been effected in appliances for the machining and preparation of ingots for rolling; in the shearing and flattening of sheets; and particularly in the bright finishing and polishing of sheet and strip metal.

We have witnessed also during the last few years a remarkable advancement in polishing machines, which, while scarcely involving new principles, has yet led to appreciably wider applications of rolled sheet and strip metal. The surface finishing of metal has unquestionably been given much greater attention during the last few years than previously, and the product of "mirror finished" rolls on the one hand, and modern grinding and polishing equipment on the other, has brought into being an entirely new standard of finish of metal surfaces; indeed, the technique of surface finishing of rolled strip and sheet metal is to-day on a far higher level than it was even so recently as three to five years ago. The use of rolls with mirror finish is now very widespread, particularly on the Continent, and it is worth while to mention that experience in the use of these rolls has directed attention in greater degree than ever before to the subject of the surface quality of metals.

The obvious limitation of mirror-finished rolls in the production of sheet metal is that some amount of "work-hardening" is inevitable, and if dead-soft metals are required, the material must subsequently pass through an annealing process.

This point leads directly to the subject of annealing, for there is no doubt that the far higher standards demanded to-day in surface finish have stimulated serious and often anxious inquiries into the possibilities of improvement in the annealing process. It is of little use to attain a high standard of surface finish on metal products if such finish is to be immediately destroyed by the operations of annealing and pickling. It is, perhaps, too much to claim that the problem of bright annealing of non-ferrous metals has been solved within the period of our present survey, but at least it may be said that it is well on the way to solution. Outstanding problems relate mainly to the working out of the most economical methods of technique.

A movement towards the construction of more efficient annealing furnaces had begun in the period between 1910 and 1915, and furnaces built on the semi-producer gas-fired principle came into use about that time in several newly constructed works and extensions. It was really this movement which started the evolution of the modern annealing furnace, since, for almost the first time in the construction of annealing furnaces for non-ferrous metals, a systematic study was made of methods for securing uniformity of temperature and efficiency in fuel consumption. That the ideal annealing furnace is not yet an accomplished fact does not in any way detract from the testimony due to the intensive efforts of furnace engineers during recent years.

While the development of electric annealing furnaces is certainly the most remarkable and symbolic of our times, tribute must be paid to the work of gas and oil engineers in improving enormously the efficiency and reliability of annealing furnaces heated with these fuels. A similar remark applies to developments in the design of furnaces using powdered coal. In this field, as in others, competition has been healthy, and has certainly been of inestimable advantage to the non-ferrous industries at large.

Extrusion.—There are yet many further developments of the last twenty-five years which deserve passing mention, but time does not permit. I cannot close, however, without referring briefly to the subject of the extrusion of metals. It can scarcely be claimed that the extrusion press itself has undergone any considerable transformation, at least, so far as fundamental principles are concerned, but extrusion presses of recent design and construction are, as a rule, much more powerful and convenient of control than those of twenty or twenty-five years ago, and they are also equipped with auxiliaries which make for greater efficiency and economy in operating. The range of extruded products has, consequently, been greatly widened.

A point that I wish to emphasise particularly, however, is that the non-ferrous engineer and metallurgist has during recent years entered into a much fuller appreciation of the value and potentialities of the extrusion process, not only as a method of direct production, but also as a hot-working process of definite metallurgical value.

Extrusion has during recent years become more than a means of producing a special type of product. It has begun to occupy an important place in the "flow of operations" of mills producing metals in forms other than extruded sections themselves. A case in point which will occur to you at once is the important part played by extrusion in the production of special alloy tubes. Wider possibilities are also opening out, and I have seen extrusion presses in some degree taking the place of hot-rolling mills in the production of strip metal by the attractive method of extruding, *e.g.*, a rectangular brass section of, say, 3·5in. or 4in. wide, 0·25in. thick, and afterwards cold-rolling it to bright finished strip. The relative accuracy of gauge and width obtainable in such an extruded product renders it a very attractive proposition for the modern high-speed precision mill. One is tempted to visualise in the not too distant future important extensions of the application of this idea.

The British Association.

No. III.

(Concluded from page 239, September 22nd.)

SECTION G (Engineering) concluded its sessions with a short meeting on Wednesday morning, September 13th, when one paper was read and discussed and three reports of Committees were presented. The President (Mr. R. W. Allen) was again in the chair.

STEEL EMBRITTLEMENT.

The authors of the paper were Messrs. A. M. Kay and R. N. Arnold, and they dealt with a number of comparatively long-time tests on various steels, in which the effect of time and temperature on embrittlement has been studied. Mentioning the desirability of any steel in practice sustaining the normal load conditions imposed upon it without deterioration during its possible life of service, the authors point out that among the disquieting features that have arisen in recent engineering development is the phenomenon of "age embrittling" of steel, which displays itself by the serious embrittling, or diminution in resistance to shock, of machine components when subjected to working conditions at elevated temperatures, a phenomenon which has been repeatedly revealed in steam and other plant subject to similar conditions. Recent research has indicated that certain alloy steels are susceptible to this embrittlement if maintained at a high temperature for a considerable period, but hitherto a systematic survey covering the phases of composition and physical state has not been attempted. A series of long-duration tests, therefore, has been carried out on various alloy steels in which dangerous embrittlement was exhibited only after long periods; in some cases as long as 1000 hours elapsed before severe embrittlement was encountered. In addition to alloy steels, some work has also been instituted on the embrittling of mild steel with time, after quenching from temperatures below the lower change point. The authors say they are not aware of any publication dealing directly with this defect in mild steel, and they are at present attempting to discover the mechanism of failure. It would appear, they state, that the failure due to the embrittlement of both alloy and mild steels is traceable to the same fundamental cause. This work—the results concerning which given in the paper relate only to the preliminary investigation of what is a very extensive subject—is being carried out at the Sheffield University under the supervision of Professor F. C. Lea, and has been rendered possible by financial assistance from the Department of Scientific and Industrial Research and the trustees of the Sir James Caird's Travelling Scholarship.

The paper describes in detail the methods and apparatus used in the investigations, and the authors arrive at the following conclusions from their work on alloy steels:—

(*a*) The ultimate embrittlement produced by soaking at temperatures from 300 deg. to 650 deg. Cent. is apparently independent of the temperature, but the rate at which the change occurs is more rapid as the temperature is increased.

(*b*) Working stresses play no apparent part in the embrittlement.

(*c*) Serious embrittlement is apt to occur in steels which contain approximately 3 per cent. nickel and 1 per cent. chromium.

(*d*) Molybdenum up to 1·5 per cent. acts as a retarding agent, but does not appear to affect the ultimate embrittlement.

The embrittlement studied in various types of steel seem, in general, to reveal the following features:

(*a*) The embrittlement is perceptible by a considerable decrease in impact resistance.

(*b*) During embrittlement the hardness varies only within small limits.

(*c*) The variation in ultimate tensile strength during embrittlement is small.

(*d*) The structures do not change appreciably as viewed under high magnification.

With regard to suggestions which have been made as to the cause of embrittlement, the authors express the view that the idea that deposition of carbides at the grain boundaries accounts for the phenomena is a doubtful explanation, as in both alloy and mild steel the embrittled structures have been examined, and no carbide has been detected at the boundaries. Furthermore, the microscope has shown that impact fractures are transcrystalline, and there is no certainty that fracture begins at crystal boundaries. It seems probable, they say, that the change in the embrittled steel is of a sub-microscopic nature. It may be that the material is attempting to attain a condition of equilibrium, and that precipitation of some constituent is taking place. In the case of mild steel it is well known that cementite (Fe_3C) is slightly soluble in ferrite. This solubility increases with temperature below the change point, so that after quenching the steel may contain dissolved Fe_3C which tends to separate with time. A long period may elapse before precipitation is complete, owing to the high forces which resist internal movement at atmospheric temperature. Precipitation, however, may be impossible at this temperature, owing to the force-resisting movement being much greater than in mild steel. An increase in temperature will relieve these forces to some extent, and may leave the material in a state which will permit the precipitation of unstable constituents. It is probable that such precipitation would result in straining the crystal lattice, and leaving the metal embrittled. However, it is not possible to put forward a more satisfactory explanation until the fundamentals of this complex problem have received more intensive analysis.

DISCUSSION.

Sir Henry Fowler said the most important question before engineers was the relation of impact and fatigue, and although he himself had not worked at temperatures as high as those used by the authors, yet the statement made by them that, in spite of the fact that there might be tremendous variation in the impact value, the fatigue value only dropped a little was of great interest. With regard to the authors' experiments at room temperature, he inquired whether that was definitely ascertained to be 20 deg. Cent. because with certain steels, particularly those with a high carbon content, a variation of a few degrees made a material difference in the impact value. He gathered that the authors' tests on alloy steels had been carried out immediately after quenching, but he did not think the effect of the small amount of ageing which took place in an ordinary tensile test was generally known. Some time ago, with a steel containing 0·6 or 0·7 carbon, it was found that the desired elongation results were not being obtained, and, as the result of a series of special tests, it was found that keeping a test bar for three or four hours after it had been quenched very materially affected the elongation, but not the tensile strength. Undoubtedly, however, the elongation was increased very materially with the comparatively small amount of ageing in that short time. He also inquired whether the tests were taken by the ordinary Brinell or the diamond hardness method.

Sir James Henderson referred to the intense local stresses set up by the Izod test, and inquired how far they might have affected the results given in the paper. Moreover, owing to quenching, there was possibly a very high state of stress on the outer skin of the material, which, together with the high temperature, might start surface cracks, and it would be interesting therefore to know if the authors had done any microstructure work to detect the presence of microscopic cracks before applying the Izod test and also afterwards.

Dr. S. J. Davies said that there was not yet a fundamental impact test. The ordinary impact test gave an indication of the shock-resisting properties of steels, but the results were, nevertheless, very vague and empirical. It was some years since he had been concerned with testing materials, and he had hoped that something new would have been found in that particular direction in the interval. All that could be said of the Izod test was that it was very useful, but not very scientific. He inquired of Sir Henry Fowler how he measured fatigue. Was it by the Wöhler test?

Sir Henry Fowler replied that he used the Haigh test.

Dr. Davies, continuing, said that since such tests were empirical a very large number were required, and as the length of time involved in making them was very considerable, it occurred to him that there might be collaboration between users for the purpose of obtaining reliable results. There was a fairly good idea, for instance, in the case of oil engines, of the mean temperature of the exhaust valve and in the case of an oil engine running under a fairly steady load, as in a marine engine, very useful results might be obtained if Professor Lea could collaborate with some superintending marine engineer to put valves of different steel into the engines. Quite a number of junior engineers were going to sea after having taken a degree at a university, and those young men would be very glad of the opportunity of doing some such scientific work, in addition to the routine work they had to carry out. At present there was a lack of data, and it was necessary to invent ways of removing it.

The President, speaking from the point of view of a designer, said that in the case of steam turbines working at from 400 lb. to 500 lb. steam pressure and 800 deg. Fah. temperature, there had been great difficulties owing to embrittlement with the bolts which secured the two halves of the turbines. Indeed, it had developed into a perfect disease all over the country at one time, and it was not confined to large turbines. After consultation with the late Sir Charles Parsons, the trouble was overcome by increasing the length of the bolts by four or five times. In the case of oil engines, trouble arose every day through embrittlement, and what was wanted was a suitable material from metallurgists, because the design was all right. Up to the present it could not be said that there was a material for bolts which overcame that difficulty. Nickel-chrome had been tried without altogether satisfactory results. In the case of the Blue Funnel line, which had a nearly complete fleet fitted with oil engines, there was a routine by which all the bolts were taken out of the engines once a year and re-annealed to prevent danger of failure from supposed fatigue.

Mr. McKay, replying to the discussion, said that owing to the limited number of furnaces available at the Sheffield University, it had not been possible to carry out work on the relation between embrittlement and fatigue, but now that it had been found that stress played no part in embrittlement it might be possible to do some work on those lines, and get some useful results. As to the effect of the variation of a few degrees from atmospheric temperature, a series of tests round about atmospheric temperature showed no difference in the results due to that variation. The hardness tests had been carried out with the diamond hardness testing machine. He agreed with Sir James Henderson as to the possibility of getting a high state of stress on the surface after quenching, but he believed, in the case of the tests, they were removed because the original 0·75in. diameter bar was afterwards turned down to 0·45in.

Mr. Arnold, who also replied, said that as to elongation increasing with time, very few steels to-day were in a stable condition after manufacture. Minute changes always took place, but whether they would be serious, he did not know. In some cases of mild steel the changes were immense, but in others they were difficult to detect. He believed steps were taken in the tests to prevent any sort of crack starting, as the result of the Izod test, because the notches were cut after heat treatment and quenching. He believed Professor Haigh had worked with slow impact tests for some time, but the results were very much like the results with the ordinary impact test.

Literature.

Plastic Working of Metals and Power Press Operations. By E. V. CRANE. London: Chapman and Hall, Ltd. Price 25s. net.

THE scope of this book is not quite so wide as its title, which should, presumably, include rolling and wire drawing, whereas only power press operations are considered. The presses described are chiefly of the crank shaft type, including excentric and toggle mechanisms; but presses of other kinds—that is, screw presses, hydraulic presses, and drop hammers—are briefly mentioned. The book deals with the behaviour of the metal worked, and, to some extent, with the shapes of the working faces of the tools. It does not concern itself with the design of presses.

The author is a member of the staff of the E. W. Bliss Company, and, in consequence, not unnaturally sings the praises of the power press. He attributes the enormous increase in output per man-hour which has taken place in recent years in the motor car industry more than in any other (in America of course) to the increased use of pressings instead of castings, &c. Examples are given showing how various articles have been made of various metals. It is claimed that much machining has been eliminated by the high order of accuracy which has been obtained in pressing.

With regard to the design of tools, it is admitted that the cut-and-try method cannot be entirely dispensed with, either in the design of tools to cut a blank of desired weight or volume, or in the design of cupping tools to give a cup with a flat top, or a top of any other desired shape.

It seems strange in a volume of this kind to see the structure of the atom discussed. Two chapters are, however, devoted to theoretical physical metallurgy for the purpose of explaining what takes place during plastic flow. These two chapters seem to belong to another book, being quite different in character from the remaining chapters, which embody a practical man's experience in dealing with the problems of his clients.

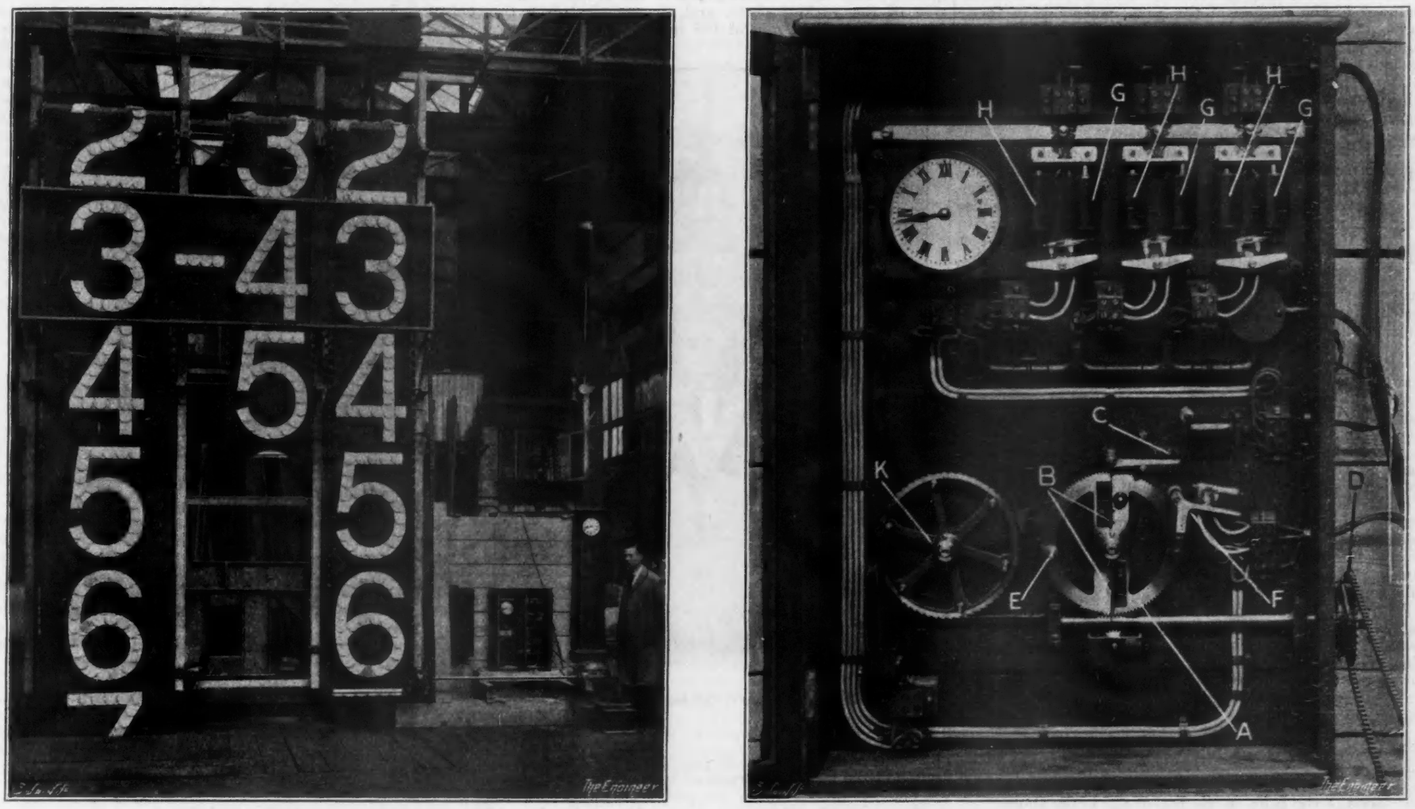
The book is full of footnotes giving references to the technical literature on the subject, nearly all the references being to American publications. It is also profusely illustrated with diagrams and photographs, all the latter being of machines of Bliss's manufacture, or of articles made in them.

Automatic feeding devices for the mass production of small articles are mentioned, but no examples are described; but safety devices to prevent press operators from injuring themselves are not even mentioned.

There are two appendices, the first consisting of a number of nomograms for the graphical calculation of the loads on the press for given operations, the capacities of given presses (taking the crank shaft as the criterion), and various other things; and the second of a number of problems to be solved by the reader by reference to the first.

CHRONOSCOPE CLOCK AND CONTROL MECHANISM

GILLETT AND JOHNSTON, CROYDON, MAKERS

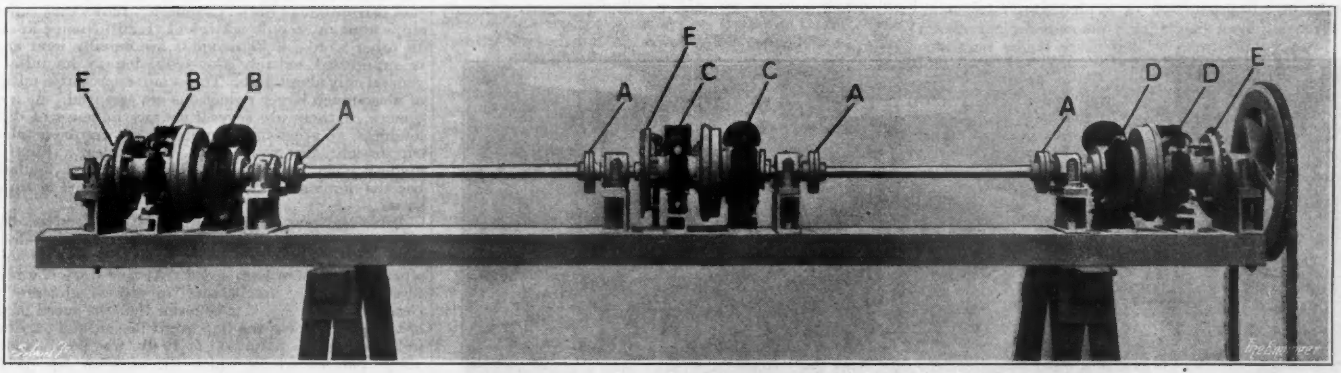


Chronoscope Clock for Paddington Station.

◆

PROMINENT amongst the features of the reconstructed Paddington Station, London, will be a giant electrical chronoscope, the largest in the world. This novel timekeeper, recently constructed by Gillett and Johnston, Ltd., Croydon, dispenses with the usual form of clock dial and indicates the hours and minutes by means of large figures, which appear in a rectangular frame and are changed at the appropriate moment by a controlling electric clock.

The sets of figures, one for the hours, a second for the tens of minutes, and a third for the digits of minutes, are mounted upon three endless bands, built up of steel slats. These slats are jointed at the ends by Delta metal links, which serve the dual purpose of providing a flexible joint between successive slats, and of transmitting the drive to the belts by engagement with the slots in the operating sprockets. Each belt has independent motion, and the movements of all three are controlled by a series of clock-actuated relays. The power for making the figure belt movements is supplied by a continuously running electric motor of ¼ H.P., coupled through a worm reduction gear to a shaft carrying the drive pulley of a heavy whittle type "V" belt.



BELT DRIVING SHAFT WITH EPICYCLIC GEAR UNITS

The driving sprockets of the figure belts are positioned at the upper ends of the belt-supporting framework, and serve both to support and operate the belts, while at the lower ends of the belts steadying rollers are fitted to ensure smoothness of action. The whittle belt transmits power from the motor to a shaft located behind the figure belts, and about 3ft. below the driving sprockets, and upon this shaft are mounted the three epicyclic gear units by which the master clock controls the movements of the figures.

A separate gear unit is provided for each figure belt, and the units are completely self-contained. Between each gear unit and its neighbour the driving shaft is divided and a flexible steel coupling, A, A, A, A, see illustration below, interposed. This precaution was taken to ensure the greatest possible freedom of action.

The epicyclic units themselves consist of a central "sun" gear of nickel steel, keyed to the driving shaft, and meshing with three phosphor-bronze "planet" pinions which, in turn, engage with a steel internal gear. This internal gear is attached to a brake drum, and the component carrying the studs on which the planet pinions run is also provided with a brake drum. A pair of externally contracting brake shoes, B B, C C, D D act upon each of these drums, and in the normal position, when the figures are stationary, the brake acting upon the planet pinions is held gripped to its drum under spring pressure, while that of the internal gear is held free of its drum by similar means.

Attached to each pair of brake shoes is a standard Marryatt and Scott brake magnet, and the windings of both these magnets are connected in series. Their action when energised is to reverse the position of the brake shoes, freeing the planet pinion component, and locking the internal gear. While no current is flowing in the brake magnets, the internal gear, being free, revolves idly, but when the reversal of action takes place the component carrying the planet pinions immediately begins to rotate, and by means of a chain sprocket, E, E, E, mounted on it, transmits its movement to the figure belt to which it is coupled. The final chain drive to the figure belt is by a Renolds chain, ⅜in. wide and of 1in. pitch.

Dealing next with the control panel, above, the main portion of this consists of a worm and worm wheel A, driven by a light chain from the continuously running shaft of the whittle belt drive pulley. The selected ratios of this mechanism provide that the worm wheel of the assembly will rotate once in slightly less than one minute, and this wheel is fitted with two spring catches B, B, at opposite points on its diameter. These catches engage with an electro-magnetic trigger release C, included in the circuit of the master clock, and as the worm wheel is completing its half revolution in slightly less time than half a minute, each of the spring catches will fall upon the locking pallet of the trigger release and remain there until the master clock impulse at exactly the half-minute unlocks it and permits it to proceed. The driven sprocket D on the worm spindle is fitted with a friction clutch which allows of it slipping round on the spindle when the spring catches are locked, but enables the drive to recommence its action the instant that the locked catch is released.

Mounted on the rim of the worm wheel is a trip pin E, and at one point, immediately after the release of the wheel at the completion of each full minute, this pin engages with and rocks over a mercury tube switch F. This, in turn, completes a circuit energising the "on" solenoid G of the minute relay. The relay is provided with two solenoids, one for making and the other for breaking the circuit it controls, and the relay is so constructed that it will remain in the position in which it is left by the last solenoid acting upon it, even after the solenoid circuit is broken.

With the completion of the circuit through the "on" solenoid, a second mercury switch, that of the minute relay, is tripped, thus closing the circuit through the brake magnets of the epicyclic gear controlling the movements of the digit minute figure belt.

The belt will then move until the next figure appears in the rectangular frame. The breaking of the brake-magnet circuit is controlled by the belt movement itself, for the belt-driving sprockets are constructed to make one complete rotation during the movement of each figure, and the spindle of the sprockets carries a quadrant arm for switching purposes. The action of this quadrant is to trip yet another mercury switch and energise the "off" solenoid H of the brake-magnet relay just as the belt movement is completed, thereby opening the brake circuit and stopping further movement of the figure belt until the pin on the worm wheel of the control panel causes the whole process to be repeated.

The action of the two further relays controlling the movements of the tens of minutes and hour figure belts is identical with that described, but a further break is included in the circuits of the "on" solenoids in these cases. These breaks take the form of simple contact points, their closing at the correct moments being controlled by pins mounted on a count wheel K, having sixty teeth, which is stepped one tooth each time the worm wheel revolves. By this means the circuits through the ten-minute and hour relays are only completed at every tenth and sixtieth minute respectively.

The only operation which the master clock is called upon to perform is the release of the trigger holding the worm wheel, yet by means of this the whole mechanism is synchronised to show accurate time. A small impulse dial is mounted in the control panel cabinet in order to indicate time and facilitate the checking of the figure belt positions.

The figures appearing on the belts have been designed to be particularly legible. They will be illuminated by flood-lighting, and as the rectangular frame in which they appear will be surrounded by a neon tube advertising sign, it was decided that the mere painting of the figures was insufficient. To give them special prominence, therefore, they are provided with circular reflectors of a special type. These reflectors are of glass, silvered and mounted in sealed metal holders, and they are very efficient in increasing the visibility of the numerals. Considerable ingenuity has been necessary in attaching these discs of glass to the slats of the belts in such a manner as to follow the shape of the figures without causing interference with the bending of the belts during the change of figures, but by careful positioning of the securing bolts this has been satisfactorily accomplished. The hour belt has twelve numerals, the minute belts five and ten respectively. The three belts together weigh over three-quarters of a ton.

Throughout the whole installation care has been taken to render the action as simple as possible, and to minimise the attention required for maintenance. To this end, ball bearings and grease-gun lubricators are employed wherever possible, and it is expected that the only attention necessary will be the periodical cleaning of the reflectors.

An interesting detail of design is the fact that the belts are self-positioning, for, as the breaking of the magnet circuits is controlled by the belt movements, the switching will occur at the correct moment independently of either the speed of the belts or the grip of the brake shoes.

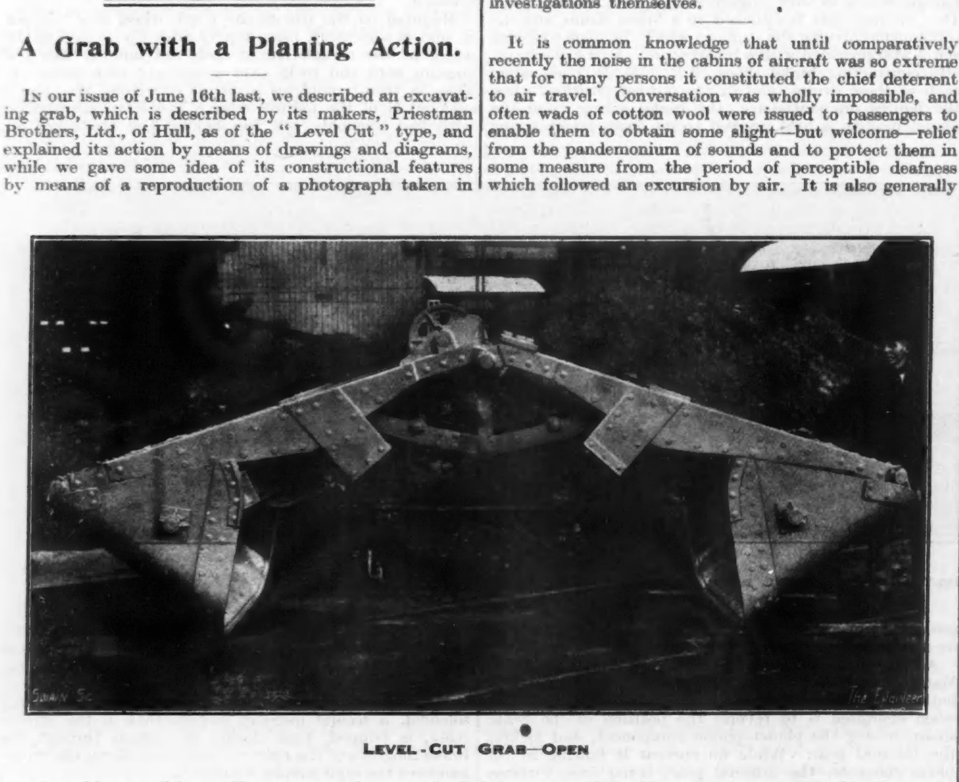
The current for operaton of the chronoscope is drawn from the 230-volt A.C. mains supplying the station. The driving motor is connected to these, while other feeders supply two sets of transformers and rectifiers. The larger of these provides the brake magnets with 140 volts D.C., and the second gives an output of 6 volts D.C. for the control panel circuits.

A feature of the installation is that it shows the hours and minutes in time-table form. This will relieve the travelling public of the necessity of transposing clock dial indications into time-table time, and will thus effect a saving of mental effort.

The timepiece will be installed by William Whiteley, Ltd., and the contract for its construction was placed with Smiths English Clocks, Ltd., in association with whom it has been designed and manufactured by Gillett and Johnston, Ltd.

A Grab with a Planing Action.

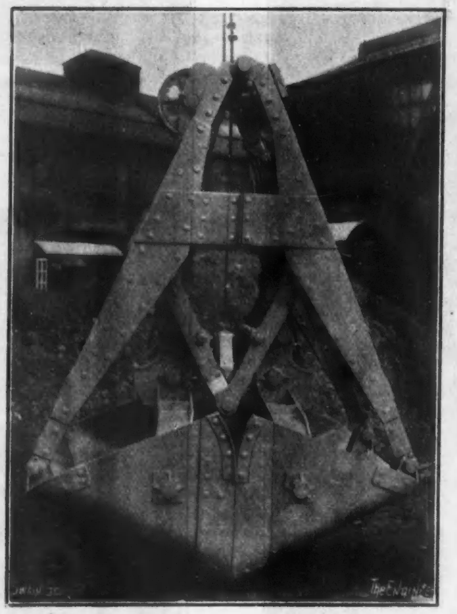
In our issue of June 16th last, we described an excavating grab, which is described by its makers, Priestman Brothers, Ltd., of Hull, as of the "Level Cut" type, and explained its action by means of drawings and diagrams, while we gave some idea of its constructional features by means of a reproduction of a photograph taken in actual working conditions. Since then, we have received from the makers two further photographs, reproduced herewith, that illustrate admirably the style of the grab and its action.



LEVEL-CUT GRAB—OPEN

It will be remembered that the object aimed at in the design of this grab is to produce a cutting action of the lips of the buckets in a horizontal plane, so that the bottom of the excavation is level, and not marked with a number of pot-holes, as is the case when a clam-shell grab is used. This action is provided by pivoting the buckets on two sets of interconnected levers and drawing them together by means of a horizontal purchase (the movement of the levers is described in our previous article).

The new pictures also show how the closing rope is kept well clear of the ground in digging, and is, consequently, relieved of much abrasion, the robust construction of the various parts, and the care taken by the makers to prevent *any* of the nuts from slacking back by securing them with split pins. It will be noticed that buffers have now been arranged between the bucket arms to take the pressure when the grab is closed.



LEVEL-CUT GRAB—CLOSED

The grab illustrated has a capacity of 1 cubic yard and weighs 33 cwt. Its height when closed is 9ft. 6in. and 5ft. 6in. open. The width is 4ft., and the spread of the jaws approximately 13ft. 6in.

Silencing Aircraft.*

By A. H. DAVIS, D.Sc., Physics Department, the National Physical Laboratory.

In 1929 a Sub-Committee was formed, by the Aeronautical Research Committee, to investigate the subject of aircraft noise. Various aspects of the work have received attention, and the present paper is an attempt to summarise the general conclusions in a form suitable for the aircraft industry, without reference to the results of the investigations themselves.

It is common knowledge that until comparatively recently the noise in the cabins of aircraft was so extreme that for many persons it constituted the chief deterrent to air travel. Conversation was wholly impossible, and often wads of cotton wool were issued to passengers to enable them to obtain some slight—but welcome—relief from the pandemonium of sounds and to protect them in some measure from the period of perceptible deafness which followed an excursion by air. It is also generally known that the cabins of certain recent aircraft are so much quieter than those of earlier types that conversation is comfortably possible and no after-deafness is noticeable.

It is not so well known how such improvement has been attained and the necessary steps are indicated below.

A Simple Scale of Noise.—Firstly, however, it would be well to realise that quite simple methods of measuring noise have proved adequate in studying the fundamentals of the problem. The sheer loudness was so great that refinements were not necessary, and a method was used in which a note of controllable loudness was produced in a telephone earpiece by means of a simple buzzer and electrical circuits. With the telephone earpiece held to one ear the current was adjusted in comparatively coarse steps (each increasing the output of sound energy by about 3·2 fold) until the sound emitted was judged to be as loud as the noise heard in the other ear. The loudness of the comparison note was read from the scale of the instrument in "decibels" above a standard zero at the threshold of audibility.

It is not necessary to discuss fully what a decibel is. It suffices to say that for all practical purposes a decibel is a definite fractional step (26 per cent.) in sound energy. The human ear works rather in a percentage or logarithmic manner, and at any ordinary loudness level a change of 1 decibel (26 per cent. change in energy) is the smallest loudness change the ear can detect. Each stud of the instrument corresponded to a step of 5 such "degrees" or decibels ($1\cdot26^5=3\cdot2$).

A series of loudness levels obtained by the writer are given in Table I. It may be remarked that, starting with a note at the threshold of audibility and gradually increasing its loudness, it is found that the sound becomes painful at about 120 db. above threshold. Again, conversation is normally impossible, even by shouting, when the noise level is of the order of 100–110 decibels above threshold—a condition which used to obtain in the cabins of passenger aircraft. Conversation is possible at a distance of a foot or so when the noise level is about 90 db., and may be carried on, though with difficulty, when—as in a tube train—the level falls to 75–80 db. The degree of comfort of conversation in trains (50 db. quiet–70 db. noisy) is well known.

TABLE I.—*Loudness Level of Various Noises.*

(Expressed in terms of the intensity in decibels above a standard "threshold" of a standard note of equal loudness.)

Loudness of comparison note decibels above appx. threshold (1 millidyne cm.^{2}).	At home.	In street.	In vehicles.	Airscrew and engine noises.
120	—	—	—	—
110	—	—	Noisy aeroplane.	Thick airscrew, high speed (80ft.).
100	—	—	—	—
90	—	Pneumatic drill.	Very noisy tube train.	Unsilenced exhaust (80ft.).
80	Very loud radio.	Motor horn (80ft.).	Tube train.	Silenced exhaust (80ft.).
70	Loud radio music.	Accelerating traffic.	Quiet aeroplane; train.	Thin airscrew, low speed (80ft.).
60	Loud radio speech.	Moderate traffic.	Bus; train.	—
50	Conversation.	Quiet car.	Quiet train.	—
40	Soft radio music.	Quiet London street.	Saloon car (25 m.p.h.).	—
30	Rustle of leaves.	Quiet street (town).	—	—
20	Quiet garden.	—	—	—
10	Quiet whisper.	—	—	—
0	Approximate threshold of audibility.*			

* Sound pressure of 1 millidyne/cm.^{2}.

It is necessary to notice an important consequence of the fact that a change of 26 per cent. in the energy is only just perceptible (1 db.). Calculation shows that three such steps amount to only a twofold ($1\cdot26^3$) change in energy. In other words, if two sounds are equally loud and one is suppressed entirely the reduction in loudness is in general only about 3 db. To get any appreciable mitigation of noise much larger reductions are essential. As a consequence, if there are several sources of noise of different loudness, no appreciable improvement can be attained by suppressing any source but the loudest. Firstly, the loudest must be reduced. Then the next loudest will become dominating, and must be suppressed in turn, and so on.

Airscrew Noise.—A comparative study upon test benches of the separate sources of aircraft noise—airscrews, engines, exhausts—showed that airscrews dominated when they were of high speed. At this stage it was therefore of primary importance to reduce airscrew noise. Generally speaking, it is believed that the speed of the tip of the airscrew was the important factor, and experiments indicated that a reduction of 10 db. was possible for each 100ft. per second by which the airscrew tip speed was reduced.

Many airscrews have tip speeds of 850ft. per second and even higher, and reduction to 550ft. per second would thus give 30 db. improvement. The quietest aircraft in which measurements have been made so far have airscrews with tip speeds of only 550ft. per second. The effects of other factors—blade setting, diameter, &c.—were small compared with the speed effect, but thin aircrew section was found to be preferable to thick, and there was probably advantage in four blader airscrews as compared with two-bladers.

Airscrew flutter must be avoided. In multi-engined machines something akin to flutter may occur when the slipstream of a front airscrew overlaps that of an airscrew further to the rear. This occurs in some machines when they yaw and gives rise to considerable bursts of noise, as well as to more rapid deterioration of the blades.

Engine and Exhaust Noise.—The adoption of large slow airscrews involves the use of reduction gear in the engine. Screaming of gears might be expected to arise, and might be serious in critical cases, but the evidence available from existing machines indicates clearly that the introduction of gearing to reduce extreme airscrew noise is well worth while.

---

* Extracted by permission of the Controller of His Majesty's Stationery Office from the Aeronautical Research Committee's R. and M., No. 1542.

At present engine clatter may be considerable and even comparable with the noise of an airscrew of medium speed. Almost certainly enclosed water-cooled engines are less noisy than unenclosed air-cooled ones. Probably the reduction of engine clatter represents one of the directions in which further advance is urgently needed, say, by confining the engine in a housing or by suitable modification of moving parts. The sleeve valve engine, which is being developed for use in aircraft as the result of investigation by the Aeronautical Research Committee, should be relatively quiet owing to the absence of poppet valve gear, and may prove to be favourable in reducing noise when it has passed the experimental stage.

At the present time exhausts of engines are not silenced to any considerable extent, and the exhaust is of the same order of noisiness as the engine. Generally speaking, silencers which will withstand the extreme conditions met in aircraft do not at present give much more than 10 decibels reduction of noise—an order of result that can be attained by the use of an exhaust pipe perforated with a large number of small holes which split the gases into a large number of small jets as they impinge on the air.

Experiments at the Royal Aircraft Establishment, Farnborough, have shown that reductions of the order of 35 decibels can be attained with silencers which get very hot internally, but which nevertheless withstand endurance tests. In view of the fact that petrol may gain access to a heated silencer when an aircraft crashes, consideration is being given to the extent to which silencers which become hot internally can be regarded as safe. The result quoted, however, is sufficient to indicate that improvements in exhaust silencing may be looked for.

Favourable Location of the Power Plant.—It should be noted that there are a number of simple common-sense features in the design of aircraft which tend to locate the passenger accommodation away from the sources of noise, or to screen the cabin from them. Particularly where airscrews are of high-speed type they should not be situated immediately to the side of passenger accommodation. In some designs of machine the tips of high-speed airscrews have been within 2ft. of the heads of passengers, with only a thin celastoid window intervening, and the machines have been exceptionally noisy. On the other hand, in a number of machines having high-speed airscrews well forward, in front of the cabin, the conditions in the cabin are comparatively quiet. This particular arrangement leads to increased noise in the region of the pilot's cockpit and possibly the best arrangement would be not to place the power plant so far forward, but to locate luggage or lavatory accommodation near it. This disposition is a feature of some of the quieter British models. In any case, when the cabin is between the wings of a biplane, engines and exhausts should not be situated there also, because in this way sound is entrapped between the wings in the vicinity of the cabin. Rather, exhaust outlets and engines should be situated above a wing or in some similar position where they are screened from the cabin. Long exhausts discharging well behind the cabin have been adopted on some machines.

There is, however, another path by which noises may reach a cabin, other than direct through the air. Any vibration set up in the structure of the aeroplane by the power plant is liable to cause resonant vibrations and rattles in the walls and fitments of the cabins. Thus engines and airscrews should be perfectly balanced to minimise vibrations. There is some evidence that, as judged by passengers in the cabin of an aeroplane, two engines attached to the wings are no noisier than one engine attached to the nose of the fuselage, although the latter is further away from the observers.

The Exclusion of Noise from Cabins.—Having considered the suppression of noise at the source, and the location of the sources as far from the cabin as possible, it remains to note the best type of cabin construction for excluding the residual noise from the passenger accommodation.

Wholly airborne sound can be excluded by the avoidance of open windows, of open apertures between the cabin and noisier parts of the machine, and of excessive cracks and gaps around doors. The latter point is of some importance, and it may perhaps be said as a guide that the combined area of cracks, gaps, ventilating inlets, &c., should not exceed one ten-thousandths of the total area of the enclosing surface of the cabin. As regards changing the air of a cabin with permanently closed windows, only a small collecting cowl inlet aperture is necessary to ensure adequate ventilation in flight, and naturally it should not be located in a noisy region.

Cabin walls consisting of one layer of doped canvas—such as were common in earlier craft—transmit the noise without any appreciable reduction, and indeed it was found that to obtain moderate soundproofing with a single thickness much heavier materials were necessary, weight proving to be the dominating factor. As a result of a search for a construction as light as possible, yet giving at least about 30 decibels reduction, it appears that cabin walls should be double, having an outer reflecting skin of metal—say, duralumin—and an inner lining of imitation leather, of plywood in small panels, or of other material. The interspace should be filled with a light fluffy material, such as "Kapok." The total weight of a satisfactory wall is about $\frac{3}{4}$ lb. to 1 lb. per square foot, the filler itself weighing about 0·2–0·4 lb. per square foot and working out, say, at about 10–20 lb. per passenger. The filler is essential since a double wall of this type, if unfilled, is often no better than one of the faces alone. In order that the insulating power of the windows should be consistent with such a wall they should be of $\frac{1}{16}$in. glass. This glass is rather heavy, so it is clear that the window area must be carefully planned to avoid windows of excessive size.

Absorption of Sound within Cabins.—Some mitigation (limited, however, to a few decibels) of the noise which gains entrance to a cabin may be achieved by the provision of upholstery and curtains, for these act as absorbents of sound, which would otherwise be reflected to and fro within the cabin.

Quality of British Engineering Products.

On February 24th, 1932, the British Chamber of Commerce in the Argentine Republic sent to the Federation of British Industries a long letter which was referred by the F.B.I. to the British Standards Institution for consideration. The substance of that letter—see THE ENGINEER, June 3rd, 1932, pages 615 and 619—was that the standard of quality of British engineering products was unnecessarily high for South American markets and was accompanied by equivalent high prices, which rendered competition with other countries difficult or impossible.

Owing to the necessity of carrying out careful inquiries, the B.S.I. was unable to send a reply to this letter to the British Chamber of Commerce in Buenos Aires until July 10th of this year, and it has only now been released for publication. This reply takes the form of two letters and a supplementary note, all of which are printed verbatim below. Further reference is made to this very important matter in a leading article to-day.

Dear Sir,—Your letter of February 24th, 1932, addressed to the Federation of British Industries, was referred to this Institution for reply in regard to the various technical questions raised therein.

It is desired to thank the Chamber of Commerce for a most useful communication and to say that this Institution greatly appreciates the spirit in which the problem has been approached.

The Engineering Divisional Council, recognising that your letter raised questions of very great importance to the British engineering export trade, gave instructions that it should be referred to the various Industry Committees of the Institution for consideration. The three Committees principally concerned were the Public Works, the Mechanical and the Electrical Industry Committees, and they, in turn, referred your letter to the appropriate Technical Committees for consideration. In addition, it was circulated to the various responsible trade organisations in this country, and inquiries as to the experience of certain British commercial agents elsewhere have also been made.

This procedure has necessarily taken a good deal of time, and the replies received have required much consideration in order to make it possible to give your Chamber of Commerce anything which could be looked upon as a general expression of opinion.

In reviewing the matter, it has been necessary for our Committees to consider, in detail, not only the basis of the present British Standards and general British practice, but also to consider carefully general British trade practices in cases where no national standards have as yet been evolved. It has, moreover, to be borne in mind that the Committees responsible for the preparation of British Standard Specifications have, as a general policy, incorporated in the specifications conditions which represent good general practice. That is to say, the specifications do not call for the highest class of material or practice except in a few special cases, but they exclude what is generally looked upon as doubtful material. In general, those responsible for the preparation of British Standard Specifications include responsible engineers and manufacturers who are used to looking at the various questions from a broad economic view point and not solely from the point of view of the actual purchase price of the machinery or product under consideration. In preparing British Standards, and certainly in the general practice of the larger British engineering and manufacturing firms, the economic importance of the export trade has therefore not been overlooked, but of necessity the conditions at home have played a dominant part.

The evidence collected, which is summarised below, would appear to indicate that on the whole there would be very much to be gained by purchasers making use of British Standards and practices. There would appear to be ample evidence to show that the reputation of British machinery has been built up on quality and durability, and that these characteristics have in the past proved effective from the point of view of sales. The British Standard in the engineering field has attained a reputation which, I am sure you will agree, ought not to be jeopardised unless there is overwhelming evidence to justify such a change in policy. We have before us evidence that whilst the salesman encounters difficulties in securing the first order, when once business has been secured the recognised superiority of the British Standard is then a substantial factor in obtaining future business.

Such recognised superiority in manufacture must obviously be of the greatest value to the British manufacturer, and any proposal which might lead to losing or even reducing that superiority would require to be considered with the greatest care and caution.

These general observations are not intended to imply that the criticisms offered by your Chamber of Commerce are not most helpful, but to remind you of the economic difficulties of accommodating modern manufacturing methods to the very diverse requirements of numerous markets.

Replying, therefore, to your letter by subjects in the order in which they have been propounded :—

Electric Generators and Motors.—The correspondent quoted, who states that the British Standard rating for industrial motors limits the temperature rise to 40 deg. Cent., whereas the American and German allow 50 deg. Cent., is correct. This, in fact, means that the British motor is 12–15 per cent. larger than the corresponding American or Continental machine. The question of bringing the British rating (40 deg.) down to the American and German rating (50 deg.) has been discussed for many years in this country and in numerous international meetings, but the great advantages of the British rating for motors for industrial purposes has always been maintained and would appear to have been established. The British motor has a very valuable overload capacity, which for industrial purposes has proved a most desirable feature, and we have secured evidence to show that Continental manufacturers export motors to compete with British motors rated on the British basis. On the other hand, there are a number of British electrical manufacturers who modify the rating when necessary to compete with American or German machines.

A more detailed reply in regard to electric motors is attached (see below).

Cranes, Derricks, Steel Structures, &c.—The Committees responsible for the British Standard Specifications for Cranes and Derricks desire to point out that the policy adopted in preparing these specifications has been to provide factors of safety no higher than is necessary to provide adequate security in operation, thus making provision for cranes as light in weight as possible, having due regard to the use of British Standard sections. Working to those standards, a crane built to the limits laid down in the specifications would, therefore, be the lightest possible, consistent with proper protection to those using it and those working in its immediate neighbourhood. The criticism of your Chamber, however, has raised the important point as to whether the existing British Standard sections might not have added to them certain other sections which would permit of the construction of cranes of adequate strength, but of lesser weight, and this point will be carefully reviewed both from the design as well as from the economic point of view.

Your Chamber's report as to the crane which permitted of the excessive overload named is difficult to deal with fully without some amplification, but it is clear to us that some cranes may have been supplied, for reasons which seemed adequate to the designer and manufacturer, which were somewhat heavier than the British Standards allow as a minimum.

With regard to the transporter bridge to which reference was made, we have ascertained that the English structure was designed to certain loads and conditions imposed by the authorities in the Argentine and does not contain an excessive amount of steel for those loads. We are not aware as to the conditions under which the German structure was designed, and in any event we are advised that neither of them would conform to good engineering practice, as the span is too short for a proper transporter bridge.

In regard to bridge design, British practice may be said to have been on a somewhat generous basis, in the light of modern experimental evidence, and the British Standard Specification is being revised to provide for higher stresses than formerly.

The same may be said to apply to building structures. The new British Standard Specification for Structural Steel for Use in Buildings permits of a possible saving of some 20 per cent. in weight of material over previous home practice. British practice has been to a certain extent dominated by the conditions laid down for structural work in London, where the safety of the public and of other buildings has been the primary consideration and no risks could be taken.

During recent years a large amount of knowledge has been accumulated, and experimental work is still being carried out on an extensive scale, and it is probable that further revisions in the standards may be brought about. It is, however, by no means certain that much further weight reductions will ensue. It can, however, be safely asserted that lightening the weights by manufacturers in other countries has been based to a certain extent on an absence of exact knowledge, a knowledge which in this country has been gained at great expense.

Oil Engines.—Your Chamber's comment that British oil engines are rated at an output which is under their maximum, whereas our competitors have no margin, is a condition which could not be corrected by any British Standard Specification. An international Committee is sitting discussing the basis for rating of oil engines, in which the British Committee is participating. The work of this international Committee will tend to diminish fictitious statements as to the capacity of oil engines. It is not anticipated that any of your associates would agree to the supply of an oil engine not capable of carrying continuously its rated output for twelve hours, and capable for periods of one hour of developing a load 10 per cent. above its rated output, without mechanical trouble. And that is the British rating.

Boilers.—In regard to boilers, your Chamber's attention is directed to the fact that British insurance rules for the design and construction of boilers compare very favourably with the American rules, but the Argentine rules for inspection of boilers specify a maximum life service at a particular steam pressure and temperature for every boiler, irrespective of its quality or condition. This rule is so obviously wrong technically as to suggest that the Argentine authorities might consider the preparation of rules for the construction of boilers so that quotations from different countries would be comparable. British Standard Specifications for the various types of boilers will shortly be available and these might be acceptable to the Argentine authorities.

Again, in this connection, whilst in the past it is probable that a good deal of inferior material has been supplied for export by manufacturing countries, it is believed that economic conditions are driving purchasers to take precautions to see that their money is being spent in the most efficient manner.

Refrigerating Compressors.—Your Chamber has gone into this matter in considerable detail and the British makers have been much interested in the views expressed. They point out that some of the points of difference referred to are due to comparing the monobloc twin-cylinder designs with British multi-cylinder designs. In the former, a centre bearing between the cranks is not admissible, because the monobloc cylinder centres are so close together that they do not allow for it. It may be remembered that the British system of independent cylinders is more convenient for spares, and that in the multi-cylinder British designs, bearings between the cranks are essential with more than two cylinders, and desirable in any case, in order to give longer life and smoother running. The complete machining of crank shafts is adopted to ensure accurate balancing at high speeds. The machining might be reduced if the demands were sufficient to warrant the preparation of a B.S. Specification which would in itself, if widely used, so co-ordinate the users' requirements as to justify the cost of the dies for drop-forged cranks for small machines.

British makers appear to favour a standard two-bearing motor for these compressors, on the grounds of quick delivery and better support for the fly-wheel, which they consider desirable.

Your Chamber's observations as to cutting out unnecessary material and labour, and also as to relative weights of British machines and those of other countries, have been studied with interest by British makers, and elicited detailed replies from them. It is not possible, in the compass of this letter, to set them out in detail, but it is claimed that the modern high-speed multi-cylinder machines of British construction would compare reasonably with the U.S.A. machines in weight, and that such difference as exists gives the British machines the advantages of better turning moment, more bearing surface, longer life, and smoother running.

Concrete Mixers and Road Machinery.—It is generally admitted that British road plant is heavier and better finished than foreign machinery, but the manufacturers in this country are unitedly of the opinion that customers in various parts of the world definitely expect a higher standard from British machinery and would be disappointed if they did not get it. The criticisms offered by your Chamber are being taken seriously into account by the British manufacturers, whose technical staff are reviewing the position. It is, however, pointed out that in general the American plant is bought in most cases just for the one job. The construction of the plant depends also on the rolled steel sections available. It would seem probable that, in the future, quotations based on plant of good quality but with less attention paid to finish will be available.

Motor Cars and Cycles.—This is a subject with which this Institution does not deal, the basis of the British horse-power rating being governed by legal statute for the purpose of taxation. It is probable that the remarkable fuel economy of the British car, and the improvement in the roads in all parts of the world, will tend to cause overseas purchasers to give preference to the British car, notwithstanding the anomalies of its rating.

Air Compressors.—The best-known British makers of air compressors have studied the comments of your Chamber. It is unfortunately true that the British manufacturer who quotes on cubic feet of free air delivered is at a disadvantage if an uninformed buyer accepts the piston displacement as the measure of the air delivered by an air compressor. Years ago British makers were compelled to fight against this practice, and have so far succeeded that they do not consider, except in quite small machines, that this is a regular practice to-day.

I am asked to point out that no purchaser would, for example, buy a steam engine or an oil engine on its piston displacement, and that it is the duty of salesmen to point out to the purchaser the obvious difference between displacement and the British makers' guarantee that the machine will actually deliver the volume of free air specified. It is considered that any return to the practice of quoting solely on piston displacement would be a retrograde and indefensible step, and that both users' and producers' interests would best be served by educating the buyer to insist on a guaranteed performance.

It would certainly be a wise step, at the present time, to give both the piston displacement and the guaranteed free air delivery, and, indeed, this is usually done. The expression "F.A.D." (free air delivered) is now being adopted in this country, and its definition is that it represents the "actual volume which the compressor will compress and deliver at the stated pressure expressed in cubic feet or cubic metres per minute at the intake and temperature and pressure." It is hoped that by persisting in the education of the buyer in this way the expression "F.A.D." will become as common and well known abroad as the expression "B.H.P." for prime movers.

Valves.—Whilst accepting the statement that the British flanges for valves and pipes are heavier and that the bolt holes are more numerous, in the case of some material delivered to customers in Buenos Aires a comparison of the British Standards and practice with the U.S. practice shows, almost throughout the whole range of flanges from low pressures up to the very highest pressures (1400 lb. per square inch), that the British flanges are smaller in diameter and lighter in weight. In general the number of bolt holes are the same, and, where different, the U.S. standards mentioned have generally larger bolt holes.

A detailed analysis is attached for the information of your Chamber.

General.—With regard to the suggestions for the adoption of the decimal system, and the relationship between the U.S. ton and the British ton, and your Chamber's proposals for the simplification of shipping documents, these have all been noted.

As a result in all British Standard Specifications the use of the pound as well as the ton is being incorporated. With regard to gallons, the difference will certainly also be made clear. It would seem that the U.S. gallon could with advantage disappear, as the British gallon so happily fits any decimal calculations.

In submitting this reply, which has been based on a large mass of information, there is a good deal of evidence to justify the broad contention that the British Standards of quality are higher than those of other countries. There is a good deal of evidence, on the other hand, to show that, whilst in the past low first cost may have been of prime importance, to-day more attention is being paid to the question of the real economic cost. Indeed, the cost of maintenance, breakdowns and repairs are becoming of greater importance and more generally recognised. This is an aspect to which I am specially desired to draw the attention of your Chamber.

It has to be remembered also that in many countries there is a growing practice of making rules and statutory regulations for the safety of workers and the public, which tend more and more to govern the construction of engineering equipment. There will therefore be an increasing tendency for British Standards of quality to be adopted in which this aspect of the matter has had a considerable influence.

The question of introducing into British Standard Specifications different grades of quality for home and export is not a policy which is viewed with any favour.

In thanking your Chamber for their most interesting and useful communication, my Institution desires me to invite your Chamber to take more direct advantage of the Local Committee of this Institution by appointing to it engineers familiar with and experienced in the industrial requirements of the Argentine. If they will then review the B.S. Specifications and transmit to us concrete proposals for any modifications which from their wide knowledge of local conditions would, in their opinion, tend to make these specifications more acceptable to purchasers in the Argentine, such proposals would, at once, be examined by the Technical Committee responsible for the particular specification under review.

The Committee would, in this way, have the great advantage of having before them specific suggestions for assisting British trade in the Argentine market and would have to consider these in the light of the demands of the home market and export markets other than the Argentine, having due regard to the economics of the situation.

The question would then be one as to whether the proposed modifications would be generally acceptable for all markets or whether they could only be applicable to the Argentine market and might have to be issued under the ægis of our Argentine Local Committee.

It is further suggested that every importer should be urged to call attention to the very valuable series of specifications issued by this Institution, copies of which are available at the offices of the Association of British Engineers in the Argentine and also at the offices of Mr. H. C. Siddeley, the local representative of the electrical manufacturers. (Signed) C. Le Maistre,
Director.

Dear Sir,—It is felt that your Chamber would be interested in a further inquiry which was undertaken by the Department of Overseas Trade in South Africa. The Department, after calling attention to some of the points which were made, sought the opinion of responsible organisations on the following four points :—

(*a*) Whether, for the purpose of that market, existing British Standard Specifications appear to involve an unnecessarily high standard of quality ;

(*b*) If so, how far this prejudices British manufacturers and exporters in competition with their foreign trade rivals ;

(*c*) To what extent the standard of quality hitherto observed in British machinery has created goodwill which is of commercial value in the market in question ;

(*d*) Whether the competitive power of the British industry would be increased by the provision of alternative British Standard Specifications, or additional grades in existing specifications, involving a lower standard of quality.

This inquiry went before the Electrical, Mechanical, and Chemical Committees of the South African Branch of the British Standards Institution and manufacturers' organisations, as well as the chief engineers of responsible public works, railways, harbours, &c., and the general consensus of opinion was that the present standards were most satisfactory and that they would deprecate a lowering of them except in the case of margins of safety applied to structural work in the British Standard Specifications, where in the past the maximum stress permitted has been 8 tons per square inch. It may interest you to know that in this particular case the Committee has already modified that figure in the light of the greater knowledge which exists to-day than when that figure was first adopted, and the British Standard Specification now allows for 9 tons instead of 8.

In all other respects the replies broadly supported the viewpoint very generally held that the standard set by the British Standard Specifications was a definite asset rather than a disadvantage in securing business in that market. (Signed) C. Le Maistre,
Director.

Electrical Generators and Motors.

The comment of the British Chamber of Commerce has reference to a correspondent's letter, which remarks :—

> "We invariably quote a 40 degree temperature rise for rotary gear, whereas the U.S.A. and the German rating is generally 50 degrees. The point, however, is lost when prices are compared, and no amount of talk would persuade an Argentine client that 40 degrees is better or necessary."

The Chamber further adds that unless a special industrial type is put forward and smaller frame sizes offered with higher temperature rise, it would be found that British goods are out of line.

It appears to have been overlooked that the motor or generator with a 40 deg. temperature rise is capable of withstanding an overload of 25 per cent. for two hours (except in the case of fractional horse-power motors), and that this overload is a fundamental part of the rating. This rating has been used in Great Britain since the first Standard Specification and is thoroughly understood. Moreover, it is preferred, after practical experience in this country of a rating without overload.

It is not, therefore, a question of putting forward smaller frame sizes with a higher temperature rise, but a question of understanding what the two ratings mean. If the two ratings are understood, without the slightest difficulty the appropriate size of motor can be selected for a given job whichever rating is selected by the purchaser.

The Chamber further remarks that British firms object to offering machines with higher temperature rises than 40 deg. Cent. This appears to have been written under a misapprehension, as we are assured by the leading British firms who stock motors in Buenos Aires that, although their motors are rated in accordance with the British Standard (*i.e.*, a 40 deg. rating with 25 per cent. overload for two hours), they are quite ready to sell machines with a corresponding 50 deg. maximum rating (the necessary factor to give this information is generally to be found on the rating plate, and is referred to in the British Standard Specification). This information also exists in their local offices in order that this may be done if desired by the customer.

It is largely a question of education and past experience whether a purchaser prefers a 50 deg. maximum rating or a 40 deg. load plus overload rating.

The 50 deg. continuous maximum rating was tried in this country some years ago, but never came into general use, owing to the fact that British engineers and designers, who had to apply the machines industrially, found a load-plus-overload rating enabled the motor to be used to the best advantage, as almost all motors have to give overloads at times.

It may be pointed out that the 25 per cent. overload is a somewhat higher figure than the corresponding 50 deg. maximum rating for that motor.

If, therefore, an agent in the Argentine has difficulty in selling a British Standard 40 deg. rise motor in competition with the foreign 50 deg. maximum rating motor made in another country, his obvious course is to ask the British manufacturer to turn his standard rating with 25 per cent. overload into a maximum rating with 50 deg. temperature rise.

Other comments in the communication from the Chamber suggest that British motors and generators are unnecessarily heavy for the purpose for which they are designed. It would be found on full examination that, although the British makers would be unwilling to adopt the light constructions which, it may be, are employed by certain foreign competitors, yet their machines do not contain waste material, and with regard to weight are comparable with the best class of foreign manufacture.

LAUNCHES AND TRIAL TRIPS.

Southern Cross, motor yacht ; built by Cammell Laird and Co., Ltd., to the order of the Melanesian Mission Trust (England), Ltd.; dimensions, 120ft. by 28ft. 6in. by 12ft. 6in. Oil engines, Gardner type ; trial trip, September 7th.

PERSONAL AND BUSINESS ANNOUNCEMENTS.

The Still Engine Company, Ltd., 10, Victoria-street, Westminster, London, S.W.1, announces that on September 5th it changed its designation to Diesel-Steam Locomotives, Ltd., in order to be more consistent with its present activities.

Following the resignation of Commander A. B. Watts and Mr. W. S. Flight from the board, Alfa-Laval Company, Ltd., announces the following appointments :—Mr. H. H. MacColl continues as chairman of the company ; Mr. J. A. Powell has been appointed general manager ; Mr. R. H. Dolton takes over control of the industrial side of the company's business ; Mr. H. Mackegg has been appointed chief representative of the marine side of the company's business ; Mr. J. M. Kennedy, of Newcastle, and Mr. John Taylor, of Liverpool, continue as the company's marine representatives in their respective areas.

Yarrow and Co., Ltd., Scotstoun, Glasgow, W.4. announce that three new directors have been appointed to the board, which now consists of : Sir Harold E. Yarrow, chairman and managing director ; Mr. W. W. Marriner ; Mr. W. E. Young ; Mr. A. L. Mellor, and Mr. W. Nithsdale. The three new members of the board, Mr. Young, Mr. Mellor, and Mr. Nithsdale, have all held responsible positions in the firm for many years. Mr. F. J. Shepherd continues to act as naval architect to the firm, and Mr. A. J. Stanyard, the secretary, is a director of the Yarrow Adriatic Shipyard, Ltd., Kraljevica, Yugoslavia.

CONTRACTS.

The British Thomson-Houston Company, Ltd., has received through Mather and Platt, Ltd., Manchester, and Candy Filter Company, Ltd., London, orders for electrical equipment for the Southport and District Water Board. The equipment consists of three 150 H.P. vertical-spindle, variable-speed A.C. commutator motors for driving bore-hole pumps, with contactor panels for each motor, and also a main sheet steel panel switchboard. In addition, there are a number of smaller motors for a variety of services. The whole of the electrical installation, including the erection and cabling work, and also the lighting for the station, is to be carried out by the B.T.H. Company.

CATALOGUES.

G. and J. Weir, Ltd., Cathcart, Glasgow, S.4.—Catalogue, Section 8, of pumps for the oil industry.

George Russell and Co., Ltd., Motherwell.—Particulars of the improved "Weddell's" sounding machine.

Renold and Coventry Chain Company, Ltd., Manchester. —1933 price list of products for industrial applications.

Ransomes and Rapier, Ltd., Ipswich.—Pamphlets on gang trolleys and the new type 3½ cubic yard excavators now made by the firm.

B.S.I. Report.—The British Standards Institution has issued its half-yearly handbook, price 1s., which includes the Report presented at the last annual general meeting, as well as the indexed list of current British Standard Specifications. The report on the activities of the three Divisions—Engineering, Building, and Chemical—provides interesting reading and shows the enormous amount of valuable work voluntarily carried out by the Institution's six hundred technical committees. The section devoted to lists of British Standard Specifications includes a numerical list, a list of the new specifications in course of preparation, and a complete subject index.

Revised Rules Applicable to Code Telegrams.—We have received from Imperial and International Communications, Ltd., of Electra House, Victoria Embankment, London, W.C.2, particulars of the revised rules applicable to code telegrams, which, as a result of the decisions reached at the recent International Telegraph Conference at Madrid, will come into force on January 1st, 1934. The ten-letter code system will be abolished and only code words not exceeding five letters will be employed. Various other regulations regarding the use of figures and groups of figures, along with full particulars of the proposed changes, are given in the revised rules.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

Difficulties of International Trade.

Although the position of the British steel industry is better than it has been for some years, this is mainly due to the steady demand from the home market. Export trade is a shade more active than for some time, but exchange fluctuations, import quotas, and the control exercised in many countries over payments to foreign creditors makes this side of the business troublesome, and at times dangerous. The fluctuations of the exchange have also raised problems which some of the international steel trade organisations find difficult to solve. This week the International Railway Manufacturers' Association, in which all the important rail-producing countries, including Great Britain and America, are included, will meet. It is obvious that price-fixing arrangements between steel industries which have to work on a gold basis and those trading in currencies which fluctuate in value like sterling and the dollar, are not easily carried out in these days. In addition, the loss of the Dutch order for rails is likely to create feeling amongst members of the Cartel, although the firm which secured the order is outside that organisation. Consumers, of course, dislike rings of manufacturers, whether international or national, and, generally speaking, are not sorry for an excuse to place an order with outsiders. Another meeting which will take place this week is that of the Management Committee of the Cartel, which has to fix a quota for the fourth quarter of the year. The last quota was placed at 500,000 metric tons per month, and was based on a minimum total of exports of 6,000,000 tons per annum. The Cartel claims that the quota figures have proved near enough to actual deliveries to be a reasonable guide for the last quarter of the year, and it is not expected that the total will be altered. The quota is not a hard-and-fast figure but is intended to be a guide for the works. This attitude was taken up when it was found impossible to collect the fines due to the old Cartel which expired some time ago.

A New Iron Ore Field.

The arrival at Glasgow of a cargo of 8000 tons of iron ore from Sierra Leone marks the beginning of an interesting development in that Colony. The ore was consigned to Wm. Baird and Co., Ltd., of Glasgow. It is of a similar type to that obtained from the iron ore fields in India, and it is anticipated that the average analysis will be 57 per cent. iron in a dry state. It contains 0·04 per cent. of phosphorus and it is claimed that it is suitable for the manufacture of foundry or basic pig iron. The deposits were discovered in 1927 and since then a railway of 3ft. 6in. gauge, 52 miles in length, has been constructed to link Marampa, where the mines are situated, with Pepel, the nearest deep-water terminus. The loading installation was supplied by the Mitchell Conveyor and Transporter Company, Ltd., of London, and the plant is designed to load steamers at the rate of 2000 tons per hour. The railway is equipped with Garratt locomotives supplied by Beyer, Peacock and Co., Ltd., of Manchester, and wagons supplied by the Metropolitan-Cammell Carriage, Wagon and Finance Company. In November, 1930, the Colonial Development Advisory Committee recommended a loan against debentures up to £500,000. The Sierra Leone Development Company, Ltd., was registered on September 20th, 1930, to develop the property, with a capital of £600,000, of which £100,000 was issued as fully paid to the vendors who had carried out the exploration of the property and the survey of the railway. The ordinary capital has been subscribed privately and there will be no public issue of capital. Amongst the firms who have supplied plant and machinery are the Cleveland Bridge and Engineering Company, Ltd., Associated British Machine Tools, Ltd., Avonside Engine Company, Ltd., Robert Hudson, Ltd., Brown, Lennox and Co., Ltd., J. and E. Hall, Ltd., Mather and Platt, Ltd., F. Braby and Co., Ltd., Stewarts and Lloyds, Ltd., Edgar Allen and Co., Ltd., and Stothert and Pitt, Ltd.

The Pig Iron Market.

Anticipations seem general that the production of pig iron will have to be increased during the autumn. In most districts the demand, if it is not level with production, is slightly in excess of it, so that stocks are being gradually depleted, and as it is unlikely that the ironmasters will want their holdings to be reduced to a very low tonnage, the outlook for an expansion in production is favourable. On the North-East Coast stocks have been depleted, and the demand still appears to be growing. The foundries and the engineers in that district are busy, and during the past week or two extra plant has been put into operation. In addition, foreign inquiries for Cleveland foundry iron have increased of late, and it looks as though business with Scandinavian markets will develop on a satisfactory scale. Business in hematite iron also has expanded to an extent which has substantially reduced the stocks, although a considerable tonnage remains in the producers' hands. Although the quotation for hematite is still 59s. 6d. for No. 1 and 59s. for mixed numbers, there is a noticeable tendency for prices to harden. In the Midlands the demand is steady and a considerable tonnage of iron is passing into consumption which is not represented by new business, as a short while ago many consumers covered their needs for some time ahead. The light castings industry is active, whilst the general founders, who have experienced depressed conditions for some time, have much improved their position. The most cheerful feature of the situation, however, is the way in which specifications are coming to hand against contracts for foundry iron, which is an indication that most branches of the consuming trades are well employed. The demand for forge iron also appears to be growing, the quotation being 57s. 6d. for Northamptonshire brands and 61s. for Derbyshire, Lincolnshire and North Staffordshire iron. During the past week a fair amount of business was transacted in East Coast hematite, as well as in Welsh hematite iron, at 75s. 6d. d/d. Although the demand for Cleveland iron from Midland consumers is not on a heavy scale, for the time being, the price has stiffened. The quotation is now about 72s. 6d. d/d Midlands for No. 3 foundry. For some time past consumers in Yorkshire have bought only for current needs, but as the stocks in makers' hands are gradually declining, they are showing an inclination to abandon this policy. In Scotland business has also been rather limited, and large contracts have been scarce.

Finished Steel Materials.

The market for finished steel materials has developed some irregularity, possibly because the Continental makers appear to have made special efforts to secure business. Whilst their quotations for overseas destinations were advanced by several shillings, as a result of the fall in the sterling exchange, the quotations for the British market were kept unchanged last week and they continued to quote £6 9s. 6d. for small bars. This competition was particularly noticeable in the Midlands, but the amount of business taken by the Continent has been comparatively small. The British re-rollers in the Midland district quote £6 15s., and in some cases a number of the makers have asked £6 17s. 6d. There is little doubt, however, that if a big order were in question the re-rollers would make drastic cuts rather than let the business go to the Continent. This week rather more orders for structural steel have come from the engineering trades. Forward contracts from the constructional engineers, however, have been scarce. Business in strip is a feature of the market. Some of the British producers have had to extend their delivery dates, and it is probable that more transactions are taking place with Continental works in the shape of orders for strip than in any other kind of steel material. The busy conditions at the works on the North-East Coast have been maintained. The constructional steel departments are well employed and the demand from this quarter has provided a welcome amount of work for the steel makers. Some inquiries which have been placed on the market for new ships have raised hopes that even the shipbuilding department, which has been the weakest section of the North-East Coast industry, may shortly experience a revival. The Yorkshire steel industry is in a better position as regards orders than for some time, especially as regards strip, whilst the activity in the motor industry is resulting in a steady call for alloy steels. The works producing stainless steel are also experiencing active trading conditions. Business in South Wales has been rather quieter of late, but the situation in the tin-plate industry is so good that it gives an appearance of activity to other sections of the market. During August the production of tin-plates reached 103,000 tons, compared with 51,200 tons for the corresponding period of last year.

The Advance in Sheet Prices.

The action of the British sheet manufacturers in advancing their prices by 5s. per ton was not unexpected. For some time the black sheet departments of most of the works have been actively engaged. The demand has lasted throughout the summer and now that the autumn trade is setting in it looks like expanding still further. The galvanised sheet section of the industry until recently has been passing through a period of severe depression; but latterly business with India has improved, whilst South Africa has been taking fair quantities and general export trading also has increased. In addition the Argentine order for about 20,000 tons, which was recently distributed amongst the British works, has placed the industry in a good position. A number of works have temporarily withdrawn from the market, so that the advance was merely a logical outcome of the increased trade. The new quotations for sheets will be found overleaf.

Current Business.

Members of the International Rail Manufacturers' Association are perturbed by the loss of a contract for Holland for 11,000 tons to 12,000 tons of rails which has been taken by the Verinigte Konigs und Laurahutte Works, which are situated in Polish Silesia. The works in Europe which are outside the European Steel Cartel have, during the past month or two, proved a thorn in the flesh of the British as well as the Continental steel makers. Only a few weeks ago the Hungarian State Works obtained a contract for 8000 tons of steel piling for the Gebel Aulia Dam, which was referred to in these columns. An interesting feature of the latter contract is the fresh disclosure that Egyptian cement is to be used in the construction of the dam. So far as can be ascertained this is the first time that cement manufactured in Egypt has been used in an important public contract in the Sudan. Fears are entertained that competition from Continental sources may result in the loss of a valuable Iraq contract in connection with the Habbaniyah irrigation scheme, which will involve the construction of a dam and the use of 1000 to 1200 tons of steel piling. It is understood that preliminary tenders have already been called for, and that the lowest have been submitted by one British and one German firm. If the contract is lost to this country, it is probable that considerable feeling will be aroused, as it is felt that, as large sums of British money have been spent in Iraq, some return in the way of business of this description might be confidently expected. The Department of Overseas Trade announces that tenders are open for the following:—South Africa: Cape Town Electricity Department, fifty automatic street-lighting controllers, to be presented in Cape Town by November 29th. Johannesburg City Council, two single-phase, 1620 kVA transformers, ratio 6600/3300 volts, to be presented in Johannesburg by October 28th. India: Indian Stores Department, Engineering Section, three electric mining and shunting locomotives with fittings and accessories, to be presented in New Delhi by October 19th. Egypt: Egyptian Ministry of Communications, Aviation Department, supply and erection of two portable aeroplane hangars at Dekheila and Mersa Matruh aerodromes, to be presented in Cairo by November 1st. Canada: H.M. Trade Commissioner's Office at Winnipeg, a boat-building firm in Western Ontario wishes to receive particulars and prices from United Kingdom manufacturers of marine Diesel engines suitable for installation in launches.

Copper and Tin.

The copper market has not recovered from the lethargic conditions which ruled last week. Although, so far as values are concerned, the American price is divorced from the European quotation, copper consumers in all parts of the world are swayed by rumours of changes in the American industry and financial situation, and are disinclined to do more than cover their immediate requirements. The position seems to be the same in all European countries, and as a consequence the market has developed weakness and the sterling quotation has dropped back to £38 c.i.f. owing to absence of business. The American producers, however, have held their price at 9c. Unofficial American estimates give the world's stocks of refined copper on August 31st at 653,000 tons, a reduction of 20,000 tons compared with the end of July. The production of refined copper in August is placed at 82,500 tons compared with 71,800 tons in the previous month. American deliveries were 47,500 tons, against 52,900 tons in July, whilst the overseas deliveries were 55,000 tons, compared with 56,000 tons in the previous month. . . . The tin market has been featureless and prices have remained comparatively steady. Such movements as have occurred have usually been traceable to reports relating to the American position. Buying by consumers, either in America or on the Continent, has been confined to a few small parcels, and speculators have shown no interest in the market. In conditions such as these comparatively small buying or selling transactions have had a disproportionate effect upon prices. It was reported this week that an attempt was likely to be made by the International Committee to persuade the Cornish tin mines to reduce their production, but it seems scarcely likely that in the present state of the industry this course will be readily agreed to. It is estimated that the American deliveries this month will amount to 6000 to 7000 tons, and there are anticipations that the visible supply will be decreased by between 2000 and 3000 tons.

Developing the Uses of Copper.

The Copper Development Association, the formation of which was referred to on this page in the issue of May 12th, has been incorporated as a company with offices at Thames House, Millbank, London, S.W.1. The conduct of detailed business will be invested in a Management Committee, of which Mr. A. D. Storke is chairman, and on which most of the important copper interests, including the trade associations, will be represented. Mr. D. P. C. Neave, general manager and secretary, will shortly submit to the Management Committee recommendations regarding the staff required, and the general lines of work to be undertaken. The Association will have sufficient funds over a period of years to ensure progress in its objects. Contact has been established with the American Copper and Brass Research Association, and with the Copper Institute of Germany, with a view to the interchange of information. It is proposed for the present to concentrate upon the development and the extended uses of copper rather than research work. It has long been urged that the large increase in the production of copper during the last decade can only be adequately taken care of by discovering new uses for the metal, and the Association will devote its energies to this purpose.

Lead and Spelter.

There have been only slight fluctuations in lead prices this week. The demand from the consumer trades in this country has been poor since the end of August, but this was to be expected after the heavy buying which then took place. At that time large contracts were placed by the building and associated trades, with manufacturers of pipes and sheets, and the latter at once covered their forward requirements. Deliveries against these contracts are well maintained, and it is estimated that this section of the industry is producing at the rate of about 1500 tons per month. Buying by Continental consumers has been rather light. As a result the lead market has had a quiet appearance, but there is no doubt that a considerable quantity of lead is passing into consumption, and any revival of buying on the part of users would quickly be reflected in higher prices. . . . Steady, but rather listless conditions have marked the spelter market for the past week or two, and there are no indications of an early change. The statistical position appears sound, and although in August production was increased from 51,217 to 53,029 tons, the stocks in the hands of the members of the Cartel at the end of the month were reduced by 3114 tons to 121,288 tons. It is generally supposed that there are considerable stocks existing outside the Cartel, but this has not influenced the market. It is reported that the Silesian producers have sold their quota for some time ahead. On the whole, this market appears to be in a sound position, and the price is held at a reasonable level. Reports from the Continent state that the International Zinc Cartel has decided to dissolve on October 31st owing to difficulties which have developed with the Belgian smelters regarding the system of levying fines on excess production. Similar reports have circulated in the past, but it has always been found possible to reach an agreement.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

Exporting Industries.

The trade policy of France is divided by two entirely opposed factors, one being the interests of agriculturists who claim the fullest measure of protection, and are obtaining it, and the other the exporting industries, which are suffering from the effects of the import quotas and other restrictions, imposed mainly for the benefit of agriculture. There are also new industries that cannot exist without these import restrictions. The exporting industries are strongly grouped, and having, as they believe, failed in their efforts to impress upon the Government the necessity for providing facilities to trade with other countries, they have joined up with the maritime Chambers of Commerce, the ports and other bodies interested in foreign trade expansion in making a collective appeal to the Prime Minister for the immediate solution of a problem that threatens the country's economic existence. This appeal is the most serious and emphatic in tone of any yet made. It points to the rapid decline of the export trade and the increasing cost of production, to the extent that manufacturers depending on foreign business have now, it is said, reached the limit of their ability to keep works in operation. Unless something is done immediately to provide facilities for an interchange of goods with other countries, they will, it is urged, be obliged to close down, and 2,000,000 workpeople will become idle. The appeal asks for an early interview with the Prime Minister in order to obtain from him a definite statement upon the Government's economic policy.

Engineering Trades.

There is some hope that the constructive and mechanical engineering industries will pass through the coming winter without suffering too much from the general inactivity. The public works programme, however, does not seem to be near realisation, and it is now proposed to prepare a new one, but it is difficult to see how anything can be done to finance these works until the Government is assured of balancing the Budget. Nevertheless, the railway companies are expected shortly to distribute orders for rolling stock, and there are some important municipal undertakings to be put in hand, such as the construction of the pumping stations, aqueduct, and reservoirs for the supply of water from the Vals de Loire to Paris, while it is announced that a ship is to be put on the stocks to replace the "Atlantique." Notwithstanding complaints of a slump in the building trades, some activity is observable, and a certain amount of structural steel is going into consumption. The reconstruction of the Carrousel Bridge across the Seine in Paris has been officially authorised. The existing cast iron bridge was built in 1834, and is now condemned as being inadequate for the traffic, while the design is criticised as lacking in artistic harmony, and it has the drawback of not being in line with the passage from the Louvre. The new bridge will be of reinforced concrete, and will have a width of about 100ft. The road between the Louvre and the Seine will pass under that carrying the traffic through the Louvre passage to the bridge.

Compagnie Generale Transatlantique.

The terms under which the Compagnie Générale Transatlantique is to be refloated have been approved by the shareholders, who have consented to wiping out the existing capital by replacing the shares with bonds entitling holders to certain dividends and a participation in surplus profits, if any. The shares held by the State are not, however, to be converted in this way, and will serve to increase the State holding and insure for it a direct control over the company's affairs. The new capital has been fixed at 218,477,000f., and there will be a public loan issue of 150,000,000f. The estimated value of the shipping owned by the company has been reduced to 1057 million francs. The buildings and all assets have been heavily depreciated. The company's losses for the past three years are shown in the balance sheet just published to have totalled 593,488,869f. Last year fifty-two ships, totalling 272,858 tons, were laid up, most of them being old vessels. Since the reconstruction of the company satisfactory progress has been made with the organisation of the services, particularly in the more economical and efficient running of lines other than the Transatlantic, and three additional ships have recently been put on the active list. Meanwhile work continues on the "Normandie," so that she can start on her maiden voyage in the spring of 1935.

A Deep Artesian Well.

It is just a century since the first artesian well was sunk in Paris, and for a long time afterwards artesian well boring provided a succession of disappointments and disasters, through want of experience in dealing with a particularly delicate operation. The sinking of a well 880 yards deep at Aulnay-sous-Bois, a north-eastern suburb of Paris, may therefore be regarded as a centenary event. The water underlying the Paris region is an infiltration from a vast subterranean supply extending from the Ardennes to the Massif Central, but knowledge of the geological formation at these depths still lacks precision, so that when a company undertook to guarantee a supply of 5000 cubic metres of water a day, and expected, on the strength of the geological plans available, to obtain water at a depth of 656 yards, the necessity of going 230 yards deeper was another disappointment to the well-borer, who was working under a fixed contract. The boring began just three months ago with a diameter of 40 cm., and as the bore had to be carried down to the water supply before inserting the 30 cm. tube, the work had to be accomplished with great precision. As the boring proceeded, clay was injected around the walls under air pressure. On Saturday last the work of lowering the tubes was successfully accomplished. There were forty-two tubes, each 20 m. long. The water has a temperature of 34 deg. Cent., and will be cooled by mixing with water at 14 deg. obtained from other wells at much smaller depths.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office, Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

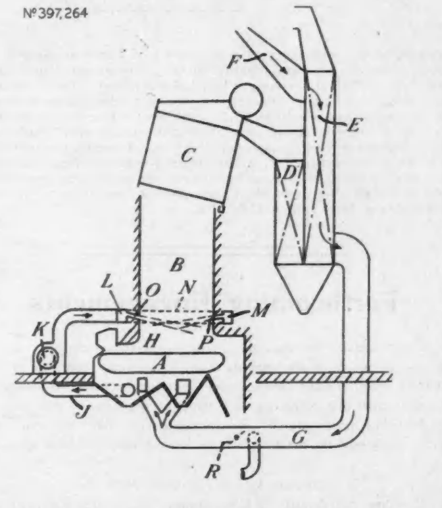
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

STEAM GENERATORS.

397,264. May 19th, 1932.—Improvements Connected with the Combustion of Fuels in Furnaces, Babcock and Wilcox, Ltd., Babcock House, Farringdon-street, London, E.C.4; and B. Samuels.

Under certain conditions with mechanical grates a great quantity of small particles of ash and incompletely burned fuel is thrown off the grate and becomes entrained in the gases sweeping up through the combustion chamber towards the boiler. These particles, on reaching the boiler tubes, cause clogging of the gas spaces and increase the frequency with which cleaning becomes necessary. In addition, a loss in efficiency is involved. In order to overcome this trouble the inventors provide downwardly inclined nozzles extending from boxes disposed in opposed walls of the combustion chamber providing downwardly directly opposed streams of relatively high-pressure air or gas forming a screen of air or gas or a mixture thereof across the furnace by which the grits and fly ash entrained in the gases passing up the combustion chamber are projected back on the grate. In the diagram A denotes the mechanical grate installed in a combustion chamber B under a boiler C, D denotes the economiser. E the air heater, and F the air inlet leading to the air heater E, Normally in a steam generating unit of this kind the gases of combustion rise up through the chamber B and pass through the tube bank of the boiler, whence they are carried downwards through the economiser D and upwards to the chimney or by induced draught fans through the air heater E. The air required for combustion is introduced under pressure at F and passed through the air heater E, being carried to the stoker by a duct G which introduces the air below the mechanical grate A. In the embodiment illustrated the lower air box is connected by a duct J with a blower K by which a part of the air delivered is drawn off from the air box and is passed through the blower K which delivers the air under pressure to boxes L, M, and N situated, for example, in the rear, front, and side walls of the combustion chamber. These boxes L, M, and N are arranged with nozzles O and P passing through the walls, which project air across the furnace as indicated so as to form a screen preventing ash and/or incompletely burned fuel passing in an upward direction among the tubes C of the boiler. The nozzles direct the air in a downwardly inclined direction, which causes the particles to return to the rear portion of the grate A, whence they pass to the ash pit.—*August 24th*, 1933.

Nº397,264

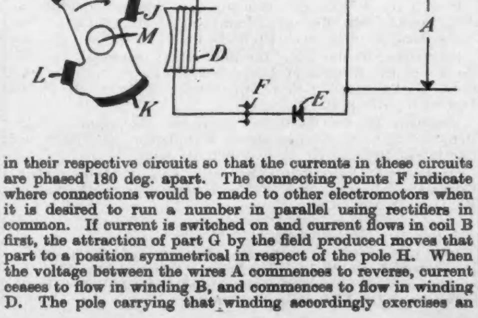


DYNAMOS AND MOTORS.

396,855. March 21st, 1932.—Electromotors, Siemens Brothers and Co., Ltd., of Caxton House, Tothill-street, London, S.W.1, and Horace Edgar Humphries, of 61, Rochester-way, Blackheath, London, S.E.3.

A motor constructed in accordance with this invention is suitable for use on a single-phase supply system. The alternating current supply is connected to wires A. The winding B is connected to these wires through a rectifier C and winding D through a rectifier E. The rectifiers may be of the dry plate type, such as the copper-copper oxide type. The rectifiers are connected in their respective circuits so that the currents in these circuits are phased 180 deg. apart. The connecting points F indicate where connections would be made to other electromotors when it is desired to run a number in parallel using rectifiers in common. If current is switched on and current flows in coil B first, the attraction of part G by the field produced moves that part to a position symmetrical in respect of the pole H. When the voltage between the wires A commences to reverse, current ceases to flow in winding B, and commences to flow in winding D. The pole carrying that winding accordingly exercises an attraction on the broad face presented by J, which is now close to the pole as compared with the edge of K The armature is accordingly turned in a clockwise direction and eventually the part G comes opposite to the pole. The next reversal of voltage causes current to flow in winding B, and an attraction is exerted on part L and K eventually comes opposite the face of pole H. The magnetic circuit is completed through the armature spindle M and a yoke in which the spindle is centred the yoke carrying the poles. Unwound poles may, however, be placed opposite to, *i.e.*, 180 deg. apart from, poles shown, separate yokes connecting opposite poles, or a common yoke connecting all poles.—*August 17th*, 1933.

Nº396,855

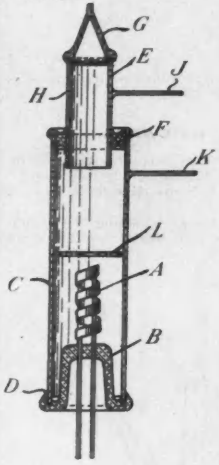


ELECTRICAL APPLIANCES.

396,998. December 16th, 1932.—Electron Discharge Devices, *Igranic Electric Company, Ltd., of* 147, *Queen Victoria-street, E.C.4.*

This invention is particularly applicable to gaseous electron discharge tubes. An electron tube which may contain, for instance, mercury vapour, has a filamentary cathode A, which is illustrated as a spiral conductor. The leading-in wires for the cathode A are embodied in a conventional seal B of glass or other refractory material. Surrounding the cathode and forming the major part of the outer enclosure of the evacuated space is a grid C in the form of a suitable metal cylinder. The grid is joined to the seal B at D in any approved manner. Mounted at the end of the grid opposite to that at which the cathode is mounted is a cylindrical metallic anode E, which is joined to the grid by means of a seal F. The cylindrical anode projects slightly beyond the seal F into the grid C, and outward beyond the seal F to form a part of the outer envelope of the evacuated space. A third seal G joined to the cylindrical anode H serves as a conduit for exhausting the vessel and is sealed off after exhaustion. It is, however, possible to seal off the vessel by closing the end of the anode by welding or other suitable means. The anode and the grid are provided with terminal wires J and K respectively. The grid is divided longitudinally into two compartments by means of a metallic partition L, which divides it into two halves except for a relatively small opening through which the discharge current between the cathode and anode may pass. A tube constructed in this manner showed much superior control characteristics as compared with the tubes without the partition.—*August 17th*, 1933.

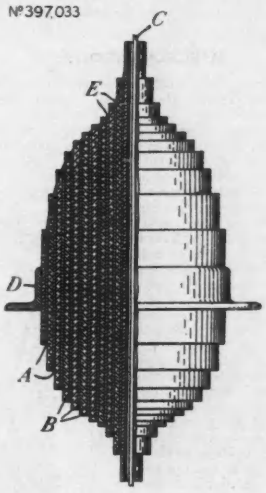
Nº396,998



397,033. February 20th, 1933.—Electrically Insulating Bushings, *Westinghouse Electric and Manufacturing Company, of East Pittsburg, Pennsylvania, U.S.A.*

This invention relates to electrically insulating bushings and particularly to outlet bushings of the condenser type for electrical apparatus, such as transformers and circuit breakers. Conducting cylinders A and dielectric cylinders B are arranged in the form of a multi-layer condenser, through which a line terminal or conductor C extends and about which an earth terminal or support D is disposed. The conducting cylinders A, preferably of relatively thin sheet material, such as lead or aluminium foil, are of decreasing lengths from the inner to the outer cylinder, so that the values of capacitance between adjacent cylinders are substantially the same. This construction provides the bushing with an intermediate cylindrical longitudinal section and tapered end sections. The length of the steps, defined by the ends of the cylinders, and the slope of the taper, depend upon the voltages involved, and the media in which the ends of the bushing are disposed. For instance, for a given voltage rating, if the bushing is disposed entirely in one dielectric medium, the end sections are preferably duplicates, whereas, if the upper end is for disposition in air and the lower end for immersion in oil, as is usually the case, the length of the upper section is preferably in accordance with the breakdown characteristics of air and the lower section of shorter length in accordance with the increased breakdown strength of the oil. Corresponding points on the upper ends of the conducting cylinders A define a curve E, which, in accordance with the invention, is a substantial reverse curve.—*August 17th*, 1933.

Nº397,033

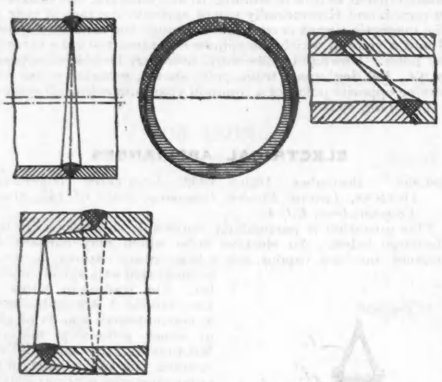


WELDING.

397,440. May 8th, 1933.—Welding Pipe Joints, E. Otto Dietrich Rohrleitungsbau Aktiengesellschaft, 2, Leopoldstrasse, Bitterfeld, Germany.

In autogenously welding together *in situ* of pipe lengths it is difficult to deposit sufficient metal on the underside of the pipe—that is to say, for the overhead weld—without making several passes. The inventors suggest, as an alternative, that, in such pipes as can be worked upon both from the inside and the outside, the weld should be made comparatively slight below and should be filled in with a deep welding from above. It is recommended that the transition from one part to another should be gradual. Several alternative joints are illustrated.—*August 24th*, 1933.

Nº397,440

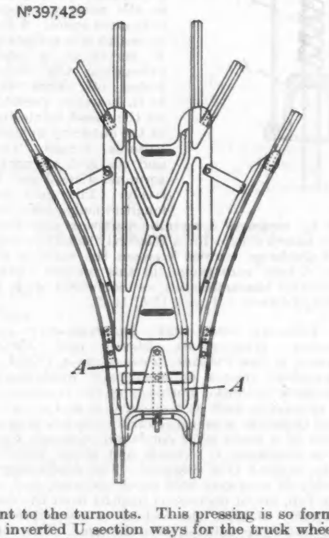


TRAMWAYS AND RAILWAYS.

397,429. April 11th, 1933.—Three-way Switches for Portable Light Railways, A. Faure, 12, Rue Verdié, Fermini (Loire), France, and A. Faure, Rue de la Loire 8, Fermini.

For the purposes of deflecting trucks to sidings on a contractor's light railway a steel pressing is placed over the main line adjacent to the turnouts. This pressing is so formed that it provides inverted U section ways for the truck wheels in all three directions, and has ramps which lead down to the normal rail level. There are tongue points at A A which may be used to deflect the trucks to either side track. These points are interconnected to prevent derailments.—*August 24th*, 1933.

Nº397,429

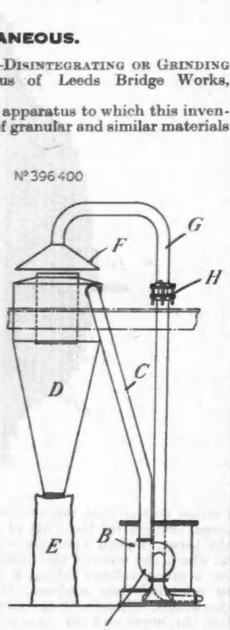


MISCELLANEOUS.

396,400. February 2nd, 1932.—Disintegrating or Grinding Apparatus, George Porteus of Leeds Bridge Works, Hunslet-lane, Leeds.

The disintegrating or grinding apparatus to which this invention applies is for the treatment of granular and similar materials and of the kind in which the disintegrator or grinder has a fan, and which delivers dust-laden air from the grinding chamber to a cyclonic dust separator or collector. With this kind of apparatus it is found that the air which escapes from the cyclonic separator or collector is not entirely free from dust, and the object of the invention is to overcome this trouble. A separate fan A is directly coupled to the rotary beater shaft of the grinder B and withdraws the ground material and dust at the discharge outlet of the grinder and elevates it by way of duct C to the upper end of a combined cyclonic settling chamber and discharge hopper D. Here the ground material falls to the bottom for delivery into bags at E, whilst the dust-laden air is drawn oft by way of a hood or canopy F in which a suction is maintained through a pipe G connected to the discharge outlet of the grinder B or otherwise so as to have suction induced therein by the action of the fan A or by the action of the grinder beaters. In order to provide for adjusting the hood or canopy F toward or away from the air outlet of the settling chamber so as to ensure that any dust from the outlet will be conducted back to the suction side of the fan and will not escape to atmosphere, the pipe G has a telescopic joint H whereby the hood may be moved up and down as desired.—*August 2nd*, 1933.

Nº396400



396,954. September 26th, 1932.—Frequency Transformation of Three-phase Current, Aktiengesellschaft Brown, Boveri and Co., of Baden, Switzerland.

A scheme is described in this specification for changing the frequency of three-phase current by means of multi-anode grid controlled rectifiers. In the diagram the feeding network of the frequency f_1 is shown at A, and the fed network of the frequency f_2 at B. The transformer C of the feeding network A is provided with three electrically separated secondary windings, D, E, F, each of which has six phases and is star-connected. To the secondary terminals of the transformer are connected the anodes of the rectifier G, which are so controlled by grids that a polyphase current of the frequency f_2 flows between its cathode H and the star points of the windings D, E, F. This polyphase current passes through the primary phase windings of the transformer J, the secondary winding of which feeds the network B. The secondary windings of the transformer C may consist of six winding sections instead of three as shown, in which case the primary winding of the transformer J will have six phases, the fed network B being three-phase. For obtaining a sine-like current of the low-frequency f_2 the phase voltages of the secondary windings D, E, F of the feeding transformer C may be of different magnitude. The grid control may be effected by commutator or by a grid transformer. According to whether the frequency ratio $f_1 : f_2$ is kept rigidly constant or is variable the commutator is driven synchronously with the frequency (f_1) of the feeding network A, or with the frequency (f_2) of the fed network B.—*August 17th*, 1933.

Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the TIME *and* PLACE *at which the meeting is to be held should be clearly stated.*

Saturday, September 30th.

Manchester Assoc. of Engineers.—Visit to works of Henry Simon, Ltd., Cheadle Heath. 2.15 p.m.

Monday, October 2nd.

Bradford Engineering Society.—Technical College, Bradford. Presidential address, "Modern Roads and Road Transport," Mr. H. Akeroyd. 7.30 p.m.

Inst. of Production Engineers: Sheffield Section.—At Royal Victoria Station Hotel, Sheffield. "Post Mortem Examinations (Metallurgy)," Mr. G. Howarth. 7.30 p.m.

Soc. of Engineers.—At Geological Society, Burlington House, W.1. "New Automatic Radial Sluice Gate," Mr. F. E. H. Shenton. 6 p.m.

Tuesday, October 3rd.

Inst. of Automobile Engineers.—At Royal Society of Arts, John-street, Adelphi, W.C.2. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7.45 p.m.

Inst. of Engineers and Shipbuilders in Scotland.—Elmbank-crescent, Glasgow. Presidential Address, Professor J. D. Cormack.

Inst. of Heating and Ventilating Engineers.—At Home Office Industrial Museum, Horseferry-road, Westminster, S.W.1. Annual general meeting. "The Trapping and Utilisation of Condensation," Mr. Alan G. Royle. 6.45 p.m.

Inst. of Marine Engineers.—85–88, The Minories, E.C.3. Presidential address. 6 p.m.

Inst. of Production Engineers: Eastern Counties Section.—At Lecture Hall, Public Library, Ipswich. "Die Casting," Mr. C. Vaughan. 7.30 p.m.

Sheffield Metallurgical Association.—198, West-street, Sheffield. "Age-hardening in Non-ferrous Alloys," Dr. L. Aitchison. 7.30 p.m.

Staffordshire Iron and Steel Inst.—At James Watt Memorial Inst., Gt. Charles-street, Birmingham. Presidential address, Mr. H. E. Cookson. 7 p.m.

Wednesday to Saturday, October 4th to October 14th.

Institute of Patentees.—Central Hall, Westminster, S.W.1. Ninth International Exhibition of Inventions. Daily.

Thursday, October 5th.

Inst. of Automobile Engineers.—At Merchant Venturers' Technical College, Bristol. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7 p.m.

Institute of Metals: Birmingham Local Section.—In the James Watt Memorial Institute, Birmingham. "The X-ray Analysis of Metals," Dr. V. E. Pullin. 7 p.m.

Institute of Metals: London Local Section.—In the Rooms of the Society of Motor Manufacturers and Traders, Ltd., 83, Pall Mall, S.W.1. Chairman's address, Mr. S. L. Archbutt. 7.30 p.m.

Midland Metallurgical Societies.—At James Watt Memorial Inst., Gt. Charles-street, Birmingham. "The X-ray Analysis of Metals," Dr. V. E. Pullin. 7 p.m.

Stephenson Locomotive Society.—No. 1, Dining Club, King's Cross Station, N.1. "The Railways of South Wales," Mr. D. S. Barrie. 6.30 p.m.

Friday, October 6th.

Inst. of Chemical Engineers.—In Rooms of Chemical Soc., Burlington House, W.1. "The Sedimentation of Fine Particles in Liquids: A Survey of Theory and Practice," Mr. R. F. Stewart and Dr. E. J. Roberts. 6 p.m.

Institution of Sanitary Engineers.—Caxton House (Hill's Restaurant), Tothill-street, Westminster, S.W.1. Opening sessional meeting. Reception, 7.30 p.m.; music and dancing, 8 p.m. until 11.30 p.m.

Inst. of Production Engineers: London Section.—At Council Room, Soc. of Motor Manufacturers and Traders, 83, Pall Mall, S.W.1. "Jig and Tool Design," Mr. E. J. H. Jones. 7.30 p.m.

Junior Inst. of Engineers.—39, Victoria-street, S.W.1. "Education with Particular Reference to the Engineer," Mr. K. W. Willans. 7.30 p.m.

Physical Society.—At Royal Institution, 21, Albemarle-street, W.1. Council meeting, 4 p.m.; extraordinary general meeting, 5.30 p.m. Thomas Young Oration, "Thomas Young and the Simplification of the Artist's Palette," Dr. Herbert E. Ives. 5.45 p.m.

Railway Club.—57, Fetter-lane, E.C.4. "Permanent Way," Mr. W. A. Willox. 7.30 p.m.

Sir John Cass Technical Institute.—Inaugural meeting. Presentations to students. Address by Sir Robert A. Johnson, K.B.E. 8.15 p.m.

Saturday, October 7th.

Inst. of British Foundrymen: Lancashire.—Engineers' Club, Albert-square, Manchester. Presidential address, "Manufacture of the Mammoth Cunard Castings," Mr. F. Swift. 3.45 p.m.

Tuesday, October 10th.

Inst. of Automobile Engineers.—At King's Head Hotel, Coventry. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7.30 p.m.

Inst. of British Foundrymen: Burnley Section.—Municipal College, Ormerod-road, Burnley. "Foundry Essentials and Incidentals," Mr. F. Whitehouse. 7.15 p.m.

Sheffield Metallurgical Association.—198, West-street, Sheffield. "Properties of Austenitic Steels," Dr. L. B. Pfeil. 7.30 p.m.

Wednesday, October 11th.

Television Soc.—At University College, Gower-street, W.C.1. "Television at the 1933 Berlin Radio Exhibition," Mr. E. H. Traub. 7 p.m.

Thursday, October 12th.

Diesel Engine Users Assoc.—Joint meeting with Inst. of Chemical Engineers, Caxton Hall, S.W.1. "Treatment of Cooling Water for Diesel Engines," Mr. L. O. Newton. 3 p.m.

Inst. of Marine Engineers: Junior Section.—85–88, The Minories, E.C.3. "'Two Milestones' in Workshop Practice," Mr. G. J. Wells. 7 p.m.

Royal Aeronautical Society.—At Royal Society of Arts, John-street, Adelphi, W.C.2. "Air Traffic Control," Major R. H. S. Mealing. 6.30 p.m.

Soc. of Chemical Industry.—At the Chemical Society, Burlington House, W.1. "Canning Fruit and Vegetables," Mr. G. Cadbury. 8 p.m.

Friday, October 13th.

Inst. of Engineers and Shipbuilders in Scotland.—Grosvenor Restaurant, Glasgow. "James Watt" dinner.

Junior Inst. of Engineers.—39, Victoria-street, S.W.1. "The Influence of Harmonics in Transformer Circuits," Mr. E. Ambrose. 7.30 p.m.

Saturday, October 14th.

Inst. of Marine Engineers: Junior Section.—85–88, The Minories, E.C.3. Social and dance. 7.30 to 11.15 p.m.

Monday, October 16th.

Bradford Engineering Soc.—Joint meeting with the Technical College, at the Technical College, Bradford. "Degreasing of Metals," Mr. H. O. Brown. 7.30 p.m.

Tuesday, October 17th.

Inst. of Marine Engineers.—85–88, The Minories, E.C.3. "Oil from Coal," Dr. W. R. Ormandy and Dr. J. Burns. 6 p.m.

Sheffield Metallurgical Soc.—198, West-street, Sheffield. "Exhaust Valve Failures," Mr. C. C. Hodgson. 7.30 p.m.

Wednesday, October 18th.

Inst. of Fuel.—At Geological Society's Rooms, Burlington House, W.1. "Recent Developments in Coking Practice," Dr.-Ing. H. Koppers. 2.30 p.m.

Inst. of Fuel.—Connaught Rooms, Great Queen-street, W.C.2. Annual dinner and dance. Presentation of the Melchett Medal to Sir John Cadman. 6.45 for 7.15 p.m.

Friday, October 20th.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1 Informal meeting; election of Sub-committee. 7 p.m.

Inst. of Sanitary Engineers.—At Caxton Hall, Westminster, S.W.1. "Aggregates for Concrete Work," Dr. Bernard H. Knight. 6 p.m.

North-East Coast Institution of Engineers and Shipbuilders.—Bolbec Hall, Newcastle-upon-Tyne. Annual general meeting. Address by the President, Mr. R. J. Walker; cinematograph film, "Mechanism of Ships' Wake," Professor T. B. Abell.

Saturday, October 21st.

Inst. of Mechanical Engineers: Graduates.—Visit to the de Havilland Aircraft Company, Stag-lane Aerodrome, Edgware.

Tuesday, October 24th.

Inst. of Automobile Engineers.—At Hotel Victoria, Wolverhampton. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7.30 p.m.

Sheffield Metallurgical Soc.—198, West-street, Sheffield. "Our Knowledge of the Conditions in the Blast-furnace," Mr. R. C. Tucker. 7.30 p.m.

Thursday, October 26th.

Inst. of Electrical Engineers.—Savoy-place, W.C.2. Presidential address, Mr. P. V. Hunter. 6 p.m.

Inst. of Mechanical Engineers.—At Dorchester Hotel, Park-lane, W.1. Annual dinner, 6.45 for 7.15 p.m.

Friday, October 27th.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. General meeting. Presidential address, Mr. Alan E. L. Chorlton. 6 p.m.

Saturday, October 28th.

Stephenson Locomotive Society.—Visit to Stratford, L.N.E. Railway Running Sheds. 2.30 p.m.

Monday, October 30th.

Bradford Engineering Soc.—Technical College, Bradford. "Salvage Work on the Ex-German Fleet at Scapa Flow," Mr. E. F. Cox. 7.30 p.m.

Inst. of Automobile Engineers.—At 39, Elmbank-crescent, Glasgow. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7.30 p.m.

Inst. of Mechanical Engineers: Graduates.—Storey's-gate, S.W.1. "Stainless Steels," Mr. F. J. Murdoch. 6.45 p.m.

Tuesday, October 31st.

Inst. of Transport.—15, Savoy-street, W.C.2. Discussion, "The Duties of a Modern Transport Manager," Mr. M. F. Barnard.

A Seven-Day Journal

◆

A 66 kV. Switchgear Contract.

An important contract for 66-kV switchgear for the new power station of the Fulham Borough Council has been placed with the Metropolitan-Vickers Electrical Company, of Trafford Park, Manchester. It will be designed to meet the specification prepared by the Council's consulting engineers, Messrs. Preece, Cardew and Rider, and Mr. A. J. Fuller, who is the Borough Electrical Engineer. The order comprises three main sections, each containing one alternator equipment, a reactor outfit, and four feeder equipments. A transfer reactor equipment and neutral earthing gear are also being supplied. When inspection is necessary, the breakers will be lifted vertically from their oil-immersed isolating contacts, and a travelling crane will be provided for each section for taking the breakers to the unloading and inspection bay, which will run across the end of each switch house. All the bus-bar connections will consist of paper-insulated conductors of the condenser type, with earthed metal armourings. Duplicate circuit breakers are being supplied for both the alternator and feeder circuits, and each breaker will be fitted with the Metrovick cross-jet explosion pot contacts designed to interrupt a short circuit of 1,500,000 kVA. Each main switchgear section will control a 75,000-kW turbo-alternator set, two of which are at present in the course of manufacture in the Metropolitan-Vickers Electrical Company's works. The control board, which will be of the vertical cubicle type, with an automatic circuit indicating diagram, will be erected in a room between the switch house and turbine-room, and an additional board of the desk type will be provided for the control of the alternators. The value of the contract is approximately £297,000.

Oil from Coal.

Large orders, we are officially informed, have been recently received by the Parkhead Forge of William Beardmore and Co., Ltd., from Imperial Chemical Industries, Ltd., for forgings required for the plant which the company is erecting at Billingham-on-Tees for the production of oil from coal by the hydrogenation process. It will be recalled that it was recently announced in our issue of September 22nd that orders for large forgings required in connection with this plant had been placed in the Sheffield district. It is gratifying to learn that Scotland is also participating in the employment which will be created by this Government-supported scheme. It is further understood that, at the invitation of Imperial Chemical Industries, Ltd., the technical staff of William Beardmore and Co., Ltd., has been in close collaboration with the technical staff of the English Steel Corporation and Thomas Firth and John Brown, Ltd., in connection with the orders for these large and special forgings, which have now been placed by Imperial Chemical Industries in Sheffield and Glasgow.

The Gasification of Towns' Refuse.

On Thursday, September 28th, an official visit of inspection was made to Burnley to see a new type of gas producer plant for town's refuse, which has been supplied to the Corporation of Burnley by Whitfield Gas Producers, Ltd., of 82, Victoria-street, London, S.W.1. The plant is at present dealing with about one-third of the refuse of the town, and the gas supplied is being utilised to raise steam in a Lancashire type boiler. As the Burnley destructor station is adjacent to the electricity station, consideration is now being given to the possibility, subject to the permission of the Electricity Commissioners and the Ministry of Health, of the production of electrical energy with gas engine driven plant. The principal features of the new Whitfield design include a system of low-pressure air supply over the whole of the multi-compartment grate to the layers of fuel immediately above the grate and enables a reduced depth of fuel to be used. There is also a marked absence of excess air in the upper parts of the producer, which prevents the burning of the gas. A volumetric analysis of the gas produced shows a content by volume of 10·2 per cent. of carbon dioxide, 0·4 per cent. of oxygen, 48·2 per cent. of nitrogen, 40 per cent. of carbon monoxide and hydrogen, and 1·2 per cent. of hydrocarbons, while an average recorded calorific value of the gas produced is 132·1 B.Th.U. per cubic foot gross, with an outlet temperature of 85·6 deg. Fah. Some interesting figures have been prepared by the borough engineer and surveyor, Mr. Arthur Race, for a plant designed to deal with the whole of the refuse of Burnley.

The Retirement of Mr. K. S. Murray.

We are informed by the British Oxygen Company, Ltd., that Mr. K. S. Murray, M.I. Mech. E., the chairman and managing director of the company has signified his intention of resigning these positions at the end of December next. Although Mr. Murray has contemplated this step for some years, he delayed taking it until the reorganisation of the business, necessitated by its various amalgamations, had been completed. Subject to the approval of the shareholders at the next annual general meeting, Mr. Murray has been appointed honorary governor for life, in recognition of his invaluable services to the company, which have extended over a period of close upon fifty years. He has also been invited and has agreed to accept the position of consulting engineer to the company, so that his unrivalled experience of the oxygen gas industry will continue to be available. The appointment of a new chairman to succeed Mr. Murray will, it is stated, be announced later. Speaking at the last annual general meeting of the company, which was held in May last, Mr. Murray referred to the bicentenary of the birth of Priestley, the discoverer of oxygen, and the early history of his own company and its experiences with the Brin barium process nearly a century later. Mr. Murray may be looked upon as the man who made oxygen a commercial product, and his many friends will wish him a long and useful life in his new capacity as honorary governor of his company.

The Uses of Tin.

According to a survey of the industrial applications of the metal tin, which has been carried out under the supervision of Mr. D. J. Macnaughtan, research director of the International Tin Research and Development Council, of Mansfield House, 378, Strand, London, W.C.2, there are nearly 200 uses of tin in manufactures. The chief industrial consumers of tin, the survey shows, are the tin-plate, automobile, heavy engineering, shipbuilding, electrical, chemical and food industries, but the range of tin-consuming industries extends further and embraces armaments, pewter, plumbing, and the manufacture of bells. The forms in which tin is employed are analysed in the survey under sections devoted to tin alloys, pure tin, tin foil, pewter, tin-plate, terne plate, tinned iron, tinned steel and copper, electro-deposited tin, and tin compounds. In the tin-alloy section mention is particularly made of bronzes for bearings, turbine blading and propellers, and the lead-tin alloys employed in type metals, pipes, solders and cable sheathing. Tin-plate is widely used for sheet metal work and the canning industries, while terne plate finds a use as roofing and in the construction of motor bodies and storage tanks. Tinned iron, steel and copper, have wide and varied uses. Electro-deposited tin is applied to the cast iron pistons of motor cars, and for the tinning of coils and component parts, while tinfoil finds extensive uses for electrical condensers, and is used in the making of ammunition for large guns, as it diminishes the fouling of the bore with copper from the driving band.

Waterloo Bridge.

In anticipation of the tenders which will in due course be invited for the reconditioning of Waterloo Bridge, the London County Council issued on Monday last an official statement with regard to the extent of the work contemplated. Piers Nos. 2, 3, 4, and 7, numbering from north abutment, are to be underpinned, while arches Nos. 5, 6, and 7, and piers Nos. 5 and 6 are to be taken down and rebuilt. The foundations of every pier except No. 1, which is incorporated in the Victoria Embankment wall, and No. 8 on the Lambeth foreshore, are to be given an effective bearing area of not less than 3000 square feet at a level of not less than 35ft. below Ordnance datum, and the carriageway is to be widened by corbelling. The scheme of reconditioning will follow the general lines of the report prepared by Messrs. Rendel, Palmer and Tritton, of Westminster, but tenderers are to be allowed certain freedom of action. They may accept the given scheme or they may submit alternative schemes for execution. Altogether the estimated cost of underpinning and corbelling-out is put at £685,000, and the treatment, so far as corbelling-out is concerned, will be subject to the approval of the Royal Fine Arts Commission. During the process of underpinning, the bridge will be entirely closed and traffic diverted to the temporary steel bridge which was erected some years ago.

Timber Research.

During the year 25,000 mechanical tests and 30,700 physical tests and other determinations on timber specimens were made at the Forest Products Research Laboratory. "Increasing appreciation," says a report which has just been issued, "of the value of laboratory tests for the elucidation of specific problems is reflected in the considerable increase in the number of requests by outside bodies for mechanical strength tests. Many of these requests have been for tests to determine the extent to which blemishes, defects, methods of treatment, &c., affect the mechanical strength properties of the material relative to particular uses." The increase in the output from the testing laboratory is stated to have been due largely to increased work for the Empire. The information derived from the tests is of particular value in connection with the Empire timbers now being introduced, since the comparison between the properties of new timbers and timbers already in use, made possible by such data, enable potential uses and markets for the new timbers to be readily ascertained. The report notes with satisfaction the increasing commercial interest displayed in Empire timbers, which is attributed partly to a genuine desire on the part of consumers to utilise Empire products more extensively, and partly to the policy of Colonial Governments in developing their forest resources more intensively. At the instance of the Empire Marketing Board the Department released an experienced officer of the Laboratory so that he could be sent by the Board to Nigeria and the Gold Coast. The visit was made possible by the co-operation of the Colonial Governments concerned, and it is confidently hoped that as a result of it more intimate contact will be established between these regions of production and consumers in the United Kingdom.

Mablethorpe Waterworks.

On Thursday, September 28th, Colonel the Right Hon. the Lord Heneage officially opened the new waterworks and sewerage works at Mablethorpe, Lincolnshire, which have been constructed to the order of the Urban District Council of Mablethorpe and Sutton, under the direction of Mr. A. E. Baker, Engineer and Surveyor to the Council, and the consulting engineers, Messrs. Silcock and Simpson, of Westminster and Leeds. The water scheme comprises a 527ft. deep bore-hole sunk into the Spilsby sandstone at the village of Maltby-le-Marsh, which has a yield of approximately 27,000 gallons of water per hour. The pumping plant consists of two treble-barrel bucket and plunger type pumps, by Tangye, each of which is designed to deliver 15,000 gallons per hour against a total head of 190ft. The pumps are designed for a normal ten hours' pumping duty and run at 24½ r.p.m. They are driven by single-cylinder heavy oil engines through double reduction gearing. A ferro-concrete water tower, 36ft. diameter and 15ft. deep, carrying 100,000 gallons of water, the top of which is 95ft. above the ground level, has been built and serves with the rising main over 11 miles of distribution pipes. The cost of the whole undertaking amounts to about £36,000. The sewerage and sewage disposal works were constructed under the direction of the same consulting engineers and comprise an extensive system of new sewers with a collecting tank and a pumping plant consisting of three Harland vertical spindle electrically driven sewage pumps. The unscreened sewage is delivered to the disposal works through a 15in. rising main. The disposal plant consists of an equalising tank with sedimentation tanks, bacteria beds, and storm water tanks, complete with Lister oil engine-driven sludge pumps and sludge drying beds. The estimated cost of the whole plant is about £42,500.

A Proposed Forth Road Bridge.

At a conference of representative local authorities, which took place at Stirling on Monday, October 2nd, a letter was read from the Ministry of Transport, stating that the Minister would be prepared to offer a grant towards the construction of a new road bridge over the river Forth, from Kincardine-on-Forth to Higgin's Neuk, at a rate of 75 per cent. of the total cost of the bridge. The proposed new bridge will, it is estimated, cost £327,000 and will be about half-a-mile in length. It will have twelve spans of 50ft. and two central spans of 150ft., which will be of the pivotal type, in order to allow ships to pass. The roadway will be carried at about 30ft. above the water level. Two years ago the Government was prepared to offer 85 per cent. of the cost, which was then estimated at £238,609, for the bridge foundations and structural steel work, and the local authorities accepted a tender from the Cleveland Bridge and Engineering Company, Ltd., of Darlington, for the work. Owing, however, to the change in financial policy the grant was withdrawn. The local authorities are now consulting with neighbouring authorities with a view to their assisting in carrying forward the scheme.

The French Liner Normandie.

In view of the revival of interest displayed in the possible early resumption of work on the large Cunard liner, now on the stocks at John Brown's Clydebank yard, and the report in favour of continuance of work on her, which, it is understood, has been made to the Government by Lord Weir, the remarks made by Monsieur Henri Cangardel, the Administrative Director-General of the Compagnie Générale Transatlantique, at the company's recent annual meeting in Paris, on the completion and operation of the "Normandie," are of special interest. Monsieur Cangardel announced that the new liner, which, it was estimated, would cost over £5,600,000 (at par), would be put into service in either April or May, 1935. The hull structure, he said, was completely finished and the turbo-electric propelling machinery was being installed. The fitting out of the ship, by reason of her large size, required much thought, but it was proceeding satisfactorily. He denied that the new liner was in any sense a monster, for she did not, he said, exceed by much the length of the last large liners designed before 1914. In view, however, of her larger engine power and the greater width of hull, her tonnage was higher than that of previous vessels. She would, he was of opinion, cross the Atlantic at a speed not conceived of formerly, and both the owners and their engineers had every hope that she would exceed her designed contract speed.

The Shipping, Engineering and Machinery Exhibition at Olympia.

No. V.

(Concluded from page 304, September 29th.)

Dobbie, McInnes and Clyde, Ltd.

In our issue of May 3rd, 1929, we described and illustrated the instrument known as the "Stabilograph," as made in accordance with the patent of Professor T. B. Abell, by Dobbie, McInnes and Clyde, Ltd., of Glasgow. An example of this instrument was included among the large variety of exhibits shown on the company's stand. It consists of a heavy compound pendulum of short period, suspended on knife edges, the movement of which is transmitted in magnified ratio through gearing to a pen arm, the pen of which traces a line on a chart fixed round a clock-driven drum. The chart is about 6in. in height, and, with the normal ratio of the gearing between the pendulum and the pen arm, the movement of the pen from the top to the foot of the chart represents an angular movement of the pendulum from +3 deg. to −3 deg. A plunger attached to the pendulum operates inside a dashpot to damp out transient vibrations.

The instrument is employed to measure the metacentric heights of ships. For this purpose the heel which it records when a known weight is applied at one side of the ship is noted, the G M thereafter being either calculated from the familiar formula or read off from a chart supplied with the instrument. The "Stabilograph" can also be used as an accelerometer to indicate changes in the speed of a ship or alternatively to show when the speed is constant. For this duty it is set up with the knife edge axis of the pendulum running athwartship. Changes in the speed of the ship will then cause the pendulum to lag behind or swing in front of the vertical position, according as the change is an acceleration or a deceleration. As an accelerometer it may be employed to record the changes of speed occurring during the launch of a ship. If the declivity of the launching ways is known, the information which it provides permits the coefficients of the initial and sliding friction to be calculated.

To measure the natural period of rolling of a ship in still water, the "Stabilograph" can be set up with its pendulum knife edge axis running fore and aft. The ship is then heeled through a small angle—necessarily less than 3 deg.—and the period of the subsequent oscillation determined by averaging the time over five or ten swings, as recorded on the chart. It is claimed that any swing which the pendulum may acquire in its own natural period during this process is not sufficient noticeably to affect the estimation of the ship's period.

For measuring the period of rolling in a seaway, the pen arm can be changed for another, the gear ratio of which is such as to reduce the magnification ratio to a tenth of its normal value. With this arm the full movement of the pen from the top to the foot of the chart corresponds with a heel from +30 deg. to −30 deg. When the instrument is required for this purpose it is fitted with a stronger damping system, consisting of a modified design of dashpot and plunger. To measure the metacentric height this same dashpot may be employed in conjunction with the standard 3 deg. pen arm.

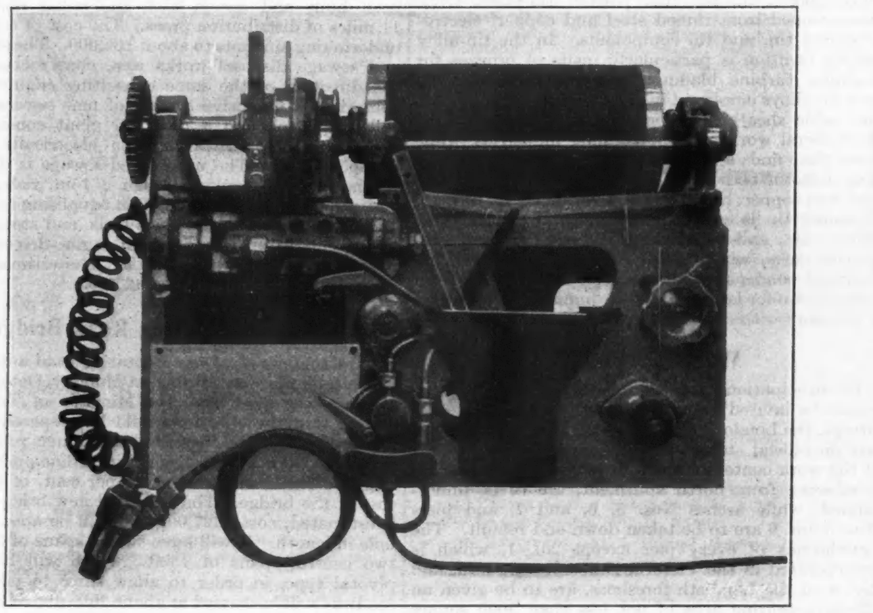

Fig. 107—"Farnboro" Electric Indicator—Dobbie, McInnes

The chart drum normally fitted makes one revolution in 20 minutes. For some purposes, as, for example, for taking high-speed acceleration diagrams, it may be replaced by a high-speed drum making one revolution in 5 minutes.

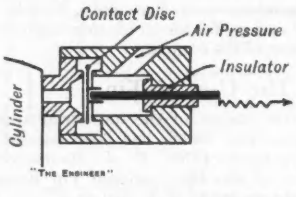

Fig. 108—Disc Valve Unit

The principle of the Farnboro (R.A.E.) electric indicator, Fig. 107, another of the firm's exhibits, was first explained in a paper by Mr. Harry Wood, presented at a meeting of the Institution of Mechanical Engineers in January, 1923. To the cylinder to be indicated, there is attached a disc valve unit, shown diagrammatically in Fig. 108, comprising a contact disc mounted on a stem which is insulated from the body of the unit. The disc is free to move through a small gap between two valve seats. Air pressure is admitted to one side of the disc and the cylinder pressure to the other. If the air pressure is maintained constant at any arbitrary value, the disc will remain in contact with the left-hand valve seat until the pressure inside the engine cylinder rises to equality with the air pressure. The disc will then move into contact with the right-hand seat, and will remain in contact with it until, later in the engine cycle, the cylinder pressure falls to equality with the air pressure when the disc will once again change its seat. The movement of the disc in either direction breaks the primary current of an electric circuit containing an induction coil. The high-tension voltage induced in the secondary circuit at the instant when the primary circuit is broken causes a spark to jump a gap in the secondary circuit. In this gap a sheet of opaque paper is situated. This paper is perforated by the spark.

The paper is mounted on a drum driven by gearing or chain from the engine crank shaft at the engine speed—or at half the engine speed in the case of a four-stroke cycle engine. The sparking point is situated at the end of a lever forming part of a link-work system, and has a motion parallel with the axis of the drum and just clear of the surface of the paper. The link-work system is moved by means of a piston coupled to one of its elements. This piston is pulled within its cylinder towards the left—in Fig. 107—by a pair of tension springs, and is moved towards the right by air pressure acting on one face of the piston. This air pressure is the same as that acting on the disc of the valve unit, Fig. 108. In this way the position of the sparking point horizontally is a measure of the air pressure, and therefore of the engine cylinder pressure at the instant at which sparking occurs. The precise value of the pressure represented can be deduced from a knowledge of the spring calibration. At the same time the vertical movement of the paper past the sparking point is a measure of the angle through which the engine crank shaft has turned. The co-ordinates of the perforated point therefore define the occurrence within the engine cylinder of a certain pressure when the crank has reached a certain angle.

In general, if the air pressure is maintained constant and the running of the engine is not altered, two sparks will occur per cycle, the first indicating the attainment by the engine pressure of a value equal to the air pressure on the rise during compression, and the second the re-attainment of equality on the fall during expansion. These two sparks will pass through the paper at the same pair of points on successive cycles. A progressive alteration in the air pressure, starting from atmospheric and increasing it, will therefore give a succession of pairs of points until the maximum engine pressure is reached, when the two points will coalesce. If the air pressure is increased beyond this point, sparking will cease. The diagram obtained is in the form shown in Fig. 109. It is a pressure-crank angle diagram, but from a knowledge of the engine dimensions it can readily be converted into the familiar pressure-volume form. The fact that any one diagram is built up over a period covering a number of successive engine cycles is advantageous, in that it eliminates the possibility, present in the case of single-cycle diagrams, of an isolated non-representative cycle being indicated.

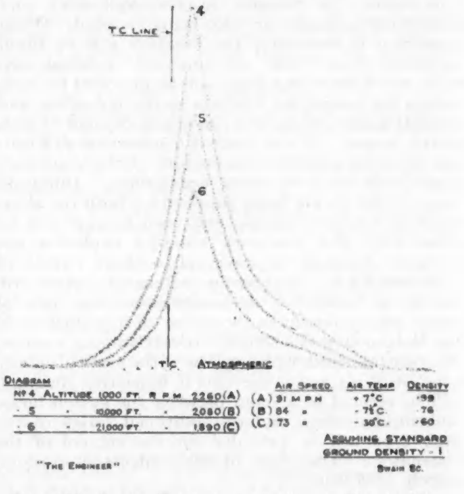

Fig. 109—Aero Engine Indicator Diagrams

The air pressure is supplied from an air bottle charged to 120 atmospheres. A bottle of about 600 cubic inches actual capacity—equivalent to 40 cubic feet free air capacity—is normally sufficient to permit fifty complete diagrams to be taken. Four different pairs of calibrated tension springs are supplied with each instrument. Their "scales" are 40 lb., 80 lb., 100 lb., and 150 lb. per square inch per inch of horizontal movement of the sparking point. They therefore permit diagrams 7½in. high to be obtained with maximum pressures of 300 lb., 600 lb., 750 lb., and 1125 lb. per square inch respectively.

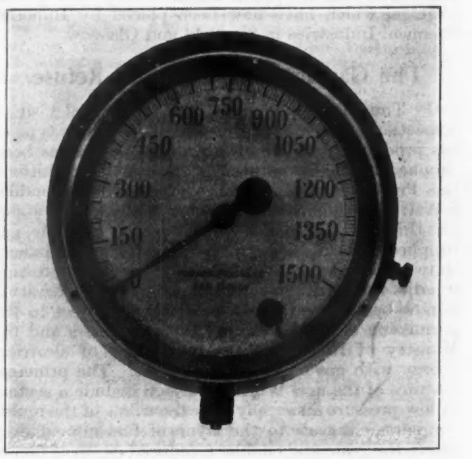

Fig. 110—Electric Maximum Pressure Gauge

The combination of tension springs and air under pressure allows the instrument to record only pressures above atmospheric. To deal with any subatmospheric portion of the cycle compression springs and a vacuum have to be employed. A pair of compression springs forms a permanent part of the piston and cylinder mechanism operating the sparking point link-work system. These two springs become effective simply when the tension springs are removed. The vacuum required is created by a small hand pump forming part of the equipment. The vacuum is applied to the disc of the valve unit and to the piston of the spring cylinder in the same way as the air pressure. The vacuum pump can be changed by means of a cock into a pressure pump, for use when light spring diagrams are required.

For indicating a multi-cylinder engine the only element which need be duplicated is the disc valve unit. With one such unit for each cylinder and a multiple-way electric switch the cylinders can be quickly indicated in succession.

A recent development consists of the introduction of a differential plunger valve unit, which permits very high pressures to be recorded, such as the fuel injection pressure in an oil engine and the manner in which it rises and falls during the injection period. This differential valve unit may be inserted anywhere in the fuel delivery pipe, and enables the injection pressure to be recorded on the same diagram as the working cylinder pressure and in correct relationship thereto with respect to the instant of occurrence. In this differential unit the disc is operated not by the pressures acting directly on its two faces, but by means of a plunger which has ten times as great an area on the air pressure side as it has on the engine pressure side. With the standard tension springs, this differential valve unit enables maximum pressures of from 3000 lb. to 11,250 lb. per square inch to be recorded. It is to be noted that the oscillating part of this unit, consisting of the disc and the differential plunger, is of relatively considerable mass, as compared with the simple disc of the normal valve unit. The differential pattern is therefore not suitable for use in conjunction with very high speeds.

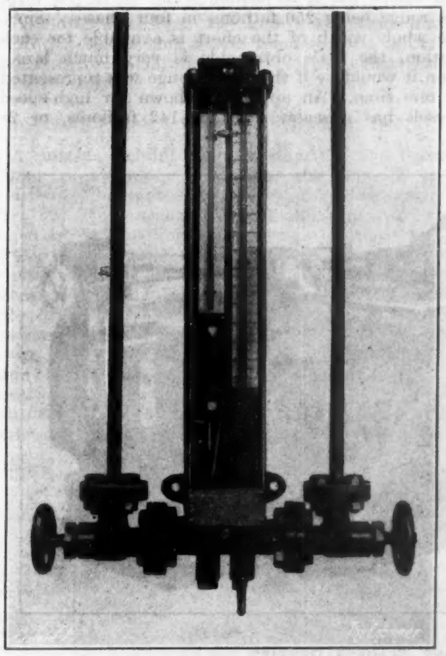

Fig. 111—"Teledep" Boiler Water Level Gauge—Dobbie, McInnes

The differential unit is also made with a 5-to-1 ratio for use in indicating compressors and supercharged engines.

Another recent development consists of an arrangement of certain auxiliary electric circuits, whereby the top dead centre line may be sparked on the diagram while an actual record is being taken, thereby eliminating the previously employed method of inscribing this line with the engine stopped. Lines of constant pressure can, in addition, be recorded on the paper during the operation of the instrument. These lines obviate the necessity for subsequent calibration.

For some purposes it is useful to be able to measure the maximum pressure occurring in a cycle without indicating the whole cycle through which the pressure passes. In these circumstances the "Farnboro" electric pressure gauge—Fig. 110—may be employed in conjunction with an air bottle and a disc valve unit, battery, and induction coil, as used in connection with the "Farnboro" indicator. The air pressure applied to one side of the disc is also applied to the gauge to move the pointer. The air gap in the secondary circuit occurs at the tip of the pointer. Hence, as the air pressure is raised sparking occurs at the tip of the pointer until the maximum pressure occurring in the cycle is reached when sparking ceases. By means of a multiway switch and distribution box, this gauge permits the maximum pressures occurring in the cylinders of a multi-cylinder engine to be determined quickly in succession.

Another interesting instrument exhibited by Dobbie, McInnes and Clyde, Ltd., was the "Teledep" remote-reading boiler water level gauge—Figs. 111 and 112. Two chambers or flanged connections C D are coupled through shut-off cocks to the boiler shell, an internal lip inside the chamber C being set 6½in. above the mean water level, and the other connection D being set at least 13in. below the datum level defined by this lip. Copper pipes A B of any length lead to the "Teledep" gauge, which may be situated at any convenient point or level below the boiler. The tubes A B terminate at valves G H leading to a central body casting, from which an inverted U tube rises upwards. This U tube consists of two glasses J K cross connected at their upper ends, and a metal body P and tube forming the lower part of the limb J. The two limbs at their lower ends are open to the valves G H respectively. Drains R and S are provided for use in connection with the charging of the gauge. In service, water fills both the tubes, the tube A being initially charged up to the datum lip and subsequently being kept full by condensation. The water enters both limbs of the U tube. It stands at different levels in the two glasses and traps a certain volume of compressed air in the upper part of the U tube. Behind the limb K there is a sliding scale graduated upwards and downwards from a zero mark at the middle of its length. A pointer on this scale opposite the 6½in. graduation above the zero is adjusted to tally with the water level in the glass J. The reading of the water level in the glass K, taken with reference to the zero of the scale, then shows the height in inches at which the water in the boiler is standing above or below the mean water level. For any changes of pressure occurring in normal working, the alteration in the level of the water in the glass J is insignificant. After a preliminary setting, therefore, the scale does not require to be adjusted each time a reading is taken.

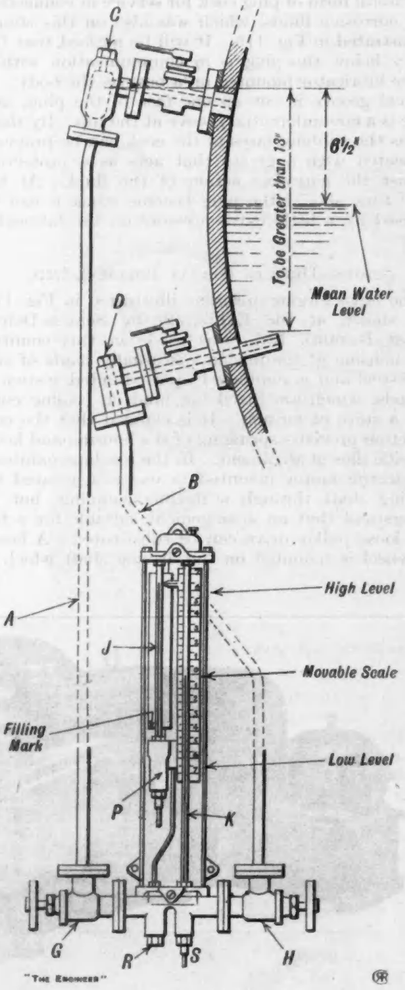

Fig. 112—"Teledep" Gauge and Fittings

A modified arrangement is provided to permit the gauge to be mounted above the level of the boiler.

Bradley and Foster, Ltd.

For those to whom cast iron is just cast iron and nothing more, a visit to the stand taken by Bradley and Foster, Ltd., of Darlaston, must have been of great interest. The exhibits consisted of a very wide range of refined pig irons with a bewildering variety of compositions, suitable for producing cast irons with various properties. One of the most interesting exhibits was a complete range of fractures of malleable pig iron designed to show the regular practice of the firm in grading into ten fractures. There can be little doubt that were some such standard system adopted universally producers of pig irons would benefit considerably. Another range of irons—blended all-mine pig—is produced by the firm in a range of compositions to suit individual requirements. The range is the outcome of extensive investigations carried out with the object of matching the properties of cold blast, Swedish, and charcoal irons, and the makers now claim that they have devised means of blending together suitable materials to match exactly the specific properties of the various cold blast and charcoal irons examined. Of particular interest to foundrymen who receive inquiries for castings of special composition, or to specified mechanical tests, were the alloy irons exhibited, many of them for the first time. The qualities ranged from low nickel-chrome irons for direct use up to various types of austenitic ingots. The variety of pig irons was so wide that it is quite impossible here to mention everything.

Loranco Ltd.

The stand of Loranco Ltd., 38, Sydenham-road, London, S.E.26, was principally devoted to small tools of foreign origin, and among them there were several of notable interest. There was, for instance, a light sensitive drilling machine driven by its own electric motor, through a belt and an automatic clutch. This clutch is brought into operation by the engagement of a spline on the drill shaft when the feed lever is pulled down, so that the motor and belt may be running continuously, but the drill spindle only starts to move when the feed is put on; the clutch slips if the feed is so gross as to endanger the drill. There were also on this stand some very high-speed rotary tools—see Fig. 113—for speeds up to 100,000 revolutions per minute. These tools are driven by little air turbines working at pressures of from 30 lb. to 100 lb. per square inch, and are notable on account of their lack of vibration. The air consumption is from 7 to 10 cubic feet per minute. With the help of a small pencil-shaped abrasive

The Shipping, Engineering and Machinery Exhibition at Olympia.

No. V.

(Concluded from page 304, September 29th.)

Dobbie, McInnes and Clyde, Ltd.

In our issue of May 3rd, 1929, we described and illustrated the instrument known as the "Stabilograph," as made in accordance with the patent of Professor T. B. Abell, by Dobbie, McInnes and Clyde, Ltd., of Glasgow. An example of this instrument was included among the large variety of exhibits shown on the company's stand. It consists of a heavy compound pendulum of short period, suspended on knife edges, the movement of which is transmitted in magnified ratio through gearing to a pen arm, the pen of which traces a line on a chart fixed round a clock-driven drum. The chart is about 6in. in height, and, with the normal ratio of the gearing between the pendulum and the pen arm, the movement of the pen from the top to the foot of the chart represents an angular movement of the pendulum from +3 deg. to −3 deg. A plunger attached to the pendulum operates inside a dashpot to damp out transient vibrations.

The instrument is employed to measure the metacentric heights of ships. For this purpose the heel which it records when a known weight is applied at one side of the ship is noted, the G M thereafter being either calculated from the familiar formula or read off from a chart supplied with the instrument. The "Stabilograph" can also be used as an accelerometer to indicate changes in the speed of a ship or alternatively to show when the speed is constant. For this duty it is set up with the knife edge axis of the pendulum running athwartship. Changes in the speed of the ship will then cause the pendulum to lag behind or swing in front of the vertical position, according as the change is an acceleration or a deceleration. As an accelerometer it may be employed to record the changes of speed occurring during the launch of a ship. If the declivity of the launching ways is known, the information which it provides permits the coefficients of the initial and sliding friction to be calculated.

To measure the natural period of rolling of a ship in still water, the "Stabilograph" can be set up with its pendulum knife edge axis running fore and aft. The ship is then heeled through a small angle—necessarily less than 3 deg.—and the period of the subsequent oscillation determined by averaging the time over five or ten swings, as recorded on the chart. It is claimed that any swing which the pendulum may acquire in its own natural period during this process is not sufficient noticeably to affect the estimation of the ship's period.

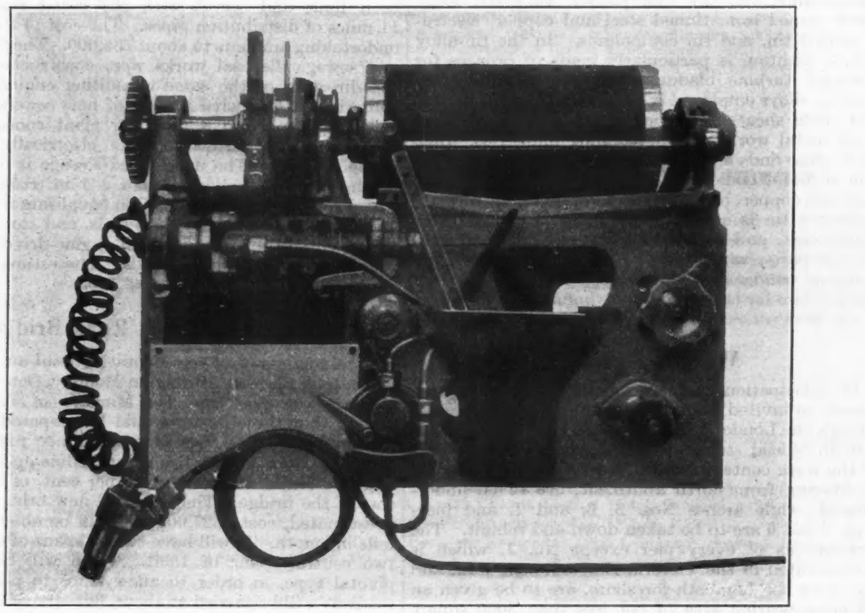

Fig. 107—"Farnboro" Electric Indicator—Dobbie, McInnes

For measuring the period of rolling in a seaway, the pen arm can be changed for another, the gear ratio of which is such as to reduce the magnification ratio to a tenth of its normal value. With this arm the full movement of the pen from the top to the foot of the chart corresponds with a heel from +30 deg. to −30 deg. When the instrument is required for this purpose it is fitted with a stronger damping system, consisting of a modified design of dashpot and plunger. To measure the metacentric height this same dashpot may be employed in conjunction with the standard 3 deg. pen arm.

The chart drum normally fitted makes one revolution in 20 minutes. For some purposes, as, for example, for taking high-speed acceleration diagrams, it may be replaced by a high-speed drum making one revolution in 5 minutes.

The principle of the Farnboro (R.A.E.) electric indicator, Fig. 107, another of the firm's exhibits, was first explained in a paper by Mr. Harry Wood, presented at a meeting of the Institution of Mechanical Engineers in January, 1923. To the cylinder to be indicated, there is attached a disc valve unit, shown diagrammatically in Fig. 108, comprising a contact disc mounted on a stem which is insulated from the body of the unit. The disc is free to move through a small gap between two valve seats. Air pressure is admitted to one side of the disc and the cylinder pressure to the other. If the air pressure is maintained constant at any arbitrary value, the disc will remain in contact with the left-hand valve seat until the pressure inside the engine cylinder rises to equality with the air pressure. The disc will then move into contact with the right-hand seat, and will remain in contact with it until, later in the engine cycle, the cylinder pressure falls to equality with the air pressure when the disc will once again change its seat. The movement of the disc in either direction breaks the primary current of an electric circuit containing an induction coil. The high-tension voltage induced in the secondary circuit at the instant when the primary circuit is broken causes a spark to jump a gap in the secondary circuit. In this gap a sheet of opaque paper is situated. This paper is perforated by the spark.

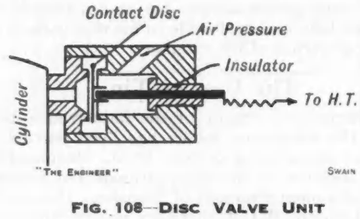

Fig. 108—Disc Valve Unit

The paper is mounted on a drum driven by gearing or chain from the engine crank shaft at the engine speed—or at half the engine speed in the case of a four-stroke cycle engine. The sparking point is situated at the end of a lever forming part of a link-work system, and has a motion parallel with the axis of the drum and just clear of the surface of the paper. The link-work system is moved by means of a piston coupled to one of its elements. This piston is pulled within its cylinder towards the left—in Fig. 107—by a pair of tension springs, and is moved towards the right by air pressure acting on one face of the piston. This air pressure is the same as that acting on the disc of the valve unit, Fig. 108. In this way the position of the sparking point horizontally is a measure of the air pressure, and therefore of the engine cylinder pressure at the instant at which sparking occurs. The precise value of the pressure represented can be deduced from a knowledge of the spring calibration. At the same time the vertical movement of the paper past the sparking point is a measure of the angle through which the engine crank shaft has turned. The co-ordinates of the perforated point therefore define the occurrence within the engine cylinder of a certain pressure when the crank has reached a certain angle.

In general, if the air pressure is maintained constant and the running of the engine is not altered, two sparks will occur per cycle, the first indicating the attainment by the engine pressure of a value equal to the air pressure on the rise during compression, and the second the re-attainment of equality on the fall during expansion. These two sparks will pass through the paper at the same pair of points on successive cycles. A progressive alteration in the air pressure, starting from atmospheric and increasing it, will therefore give a succession of pairs of points until the maximum engine pressure is reached, when the two points will coalesce. If the air pressure is increased beyond this point, sparking will cease. The diagram obtained is in the form shown in Fig. 109. It is a pressure-crank angle diagram, but from a knowledge of the engine dimensions it can readily be converted into the familiar pressure-volume form. The fact that any one diagram is built up over a period covering a number of successive engine cycles is advantageous, in that it eliminates the possibility, present in the case of single-cycle diagrams, of an isolated non-representative cycle being indicated.

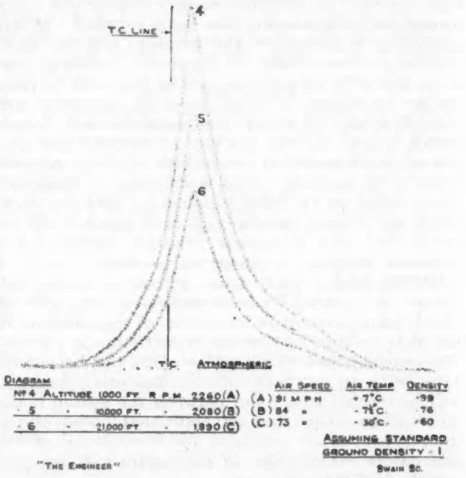

Fig. 109—Aero Engine Indicator Diagrams

The air pressure is supplied from an air bottle charged to 120 atmospheres. A bottle of about 600 cubic inches actual capacity—equivalent to 40 cubic feet free air capacity—is normally sufficient to permit fifty complete diagrams to be taken. Four different pairs of calibrated tension springs are supplied with each instrument. Their "scales" are 40 lb., 80 lb., 100 lb., and 150 lb. per square inch per inch of horizontal movement of the sparking point. They therefore permit diagrams 7½in. high to be obtained with maximum pressures of 300 lb., 600 lb., 750 lb., and 1125 lb. per square inch respectively.

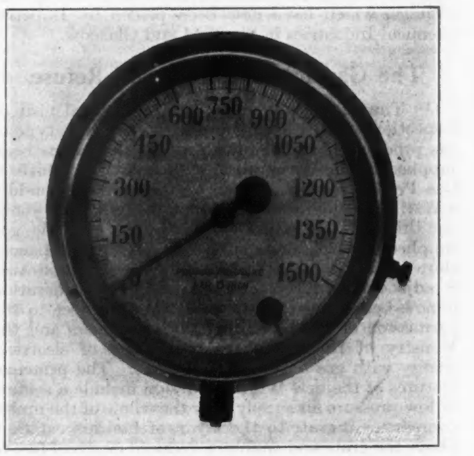

Fig. 110—Electric Maximum Pressure Gauge

The combination of tension springs and air under pressure allows the instrument to record only pressures above atmospheric. To deal with any sub-atmospheric portion of the cycle compression springs and a vacuum have to be employed. A pair of compression springs forms a permanent part of the piston and cylinder mechanism operating the sparking point link-work system. These two springs become effective simply when the tension springs are removed. The vacuum required is created by a small hand pump forming part of the equipment. The vacuum is applied to the disc of the valve unit and to the piston of the spring cylinder in the same way as the air pressure. The vacuum pump can be changed by means of a cock into a pressure pump, for use when light spring diagrams are required.

For indicating a multi-cylinder engine the only element which need be duplicated is the disc valve unit. With one such unit for each cylinder and a multiple-way electric switch the cylinders can be quickly indicated in succession.

A recent development consists of the introduction of a differential plunger valve unit, which permits very high pressures to be recorded, such as the fuel injection pressure in an oil engine and the manner in which it rises and falls during the injection period. This differential valve unit may be inserted anywhere in the fuel delivery pipe, and enables the injection pressure to be recorded on the same diagram as the working cylinder pressure and in correct relationship thereto with respect to the instant of occurrence. In this differential unit the disc is operated not by the pressures acting directly on its two faces, but by means of a plunger which has ten times as great an area on the air pressure side as it has on the engine pressure side. With the standard tension springs, this differential valve unit enables maximum pressures of from 3000 lb. to 11,250 lb. per square inch to be recorded. It is to be noted that the oscillating part of this unit, consisting of the disc and the differential plunger, is of relatively considerable mass, as compared with the simple disc of the normal valve unit. The differential pattern is therefore not suitable for use in conjunction with very high speeds.

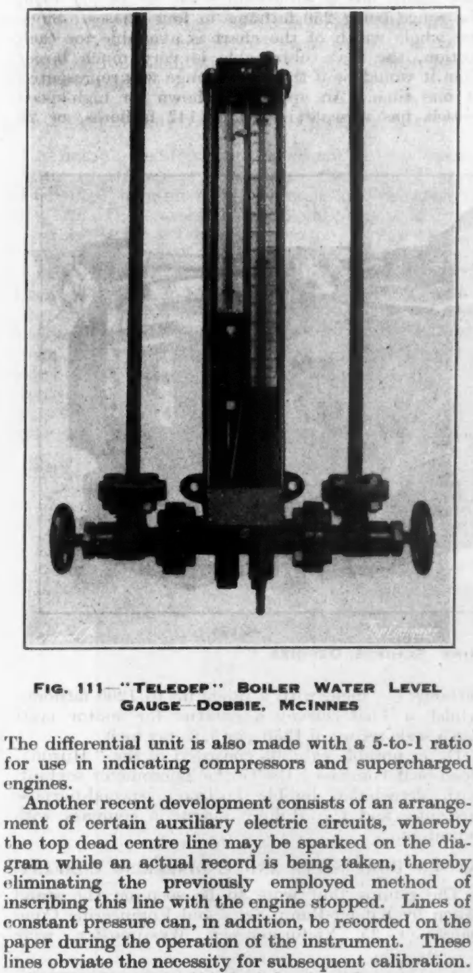

Fig. 111—"Teledep" Boiler Water Level Gauge—Dobbie, McInnes

The differential unit is also made with a 5-to-1 ratio for use in indicating compressors and supercharged engines.

Another recent development consists of an arrangement of certain auxiliary electric circuits, whereby the top dead centre line may be sparked on the diagram while an actual record is being taken, thereby eliminating the previously employed method of inscribing this line with the engine stopped. Lines of constant pressure can, in addition, be recorded on the paper during the operation of the instrument. These lines obviate the necessity for subsequent calibration.

For some purposes it is useful to be able to measure the maximum pressure occurring in a cycle without indicating the whole cycle through which the pressure passes. In these circumstances the "Farnboro" electric pressure gauge—Fig. 110—may be employed in conjunction with an air bottle and a disc valve unit, battery, and induction coil, as used in connection with the "Farnboro" indicator. The air pressure applied to one side of the disc is also applied to the gauge to move the pointer. The air gap in the secondary circuit occurs at the tip of the pointer. Hence, as the air pressure is raised sparking occurs at the tip of the pointer until the maximum pressure occurring in the cycle is reached when sparking ceases. By means of a multiway switch and distribution box, this gauge permits the maximum pressures occurring in the cylinders of a multi-cylinder engine to be determined quickly in succession.

Another interesting instrument exhibited by Dobbie, McInnes and Clyde, Ltd., was the "Teledep" remote-reading boiler water level gauge—Figs. 111 and 112. Two chambers or flanged connections C D are coupled through shut-off cocks to the boiler shell, an internal lip inside the chamber C being set 6½in. above the mean water level, and the other connection D being set at least 13in. below the datum level defined by this lip. Copper pipes A B of any length lead to the "Teledep" gauge, which may be situated at any convenient point or level below the boiler. The tubes A B terminate at valves G H leading to a central body casting, from which an inverted U tube rises upwards. This U tube consists of two glasses J K cross connected at their upper ends, and a metal body P and tube forming the lower part of the limb J. The two limbs at their lower ends are open to the valves G H respectively. Drains R and S are provided for use in connection with the charging of the gauge. In service, water fills both the tubes, the tube A being initially charged up to the datum lip and subsequently being kept full by condensation. The water enters both limbs of the U tube. It stands at different levels in the two glasses and traps a certain volume of compressed air in the upper part of the U tube. Behind the limb K there is a sliding scale graduated upwards and downwards from a zero mark at the middle of its length. A pointer on this scale opposite the 6½in. graduation above the zero is adjusted to tally with the water level in the glass J. The reading of the water level in the glass K, taken with reference to the zero of the scale, then shows the height in inches at which the water in the boiler is standing above or below the mean water level. For any changes of pressure occurring in normal working, the alteration in the level of the water in the glass J is insignificant. After a preliminary setting, therefore, the scale does not require to be adjusted each time a reading is taken.

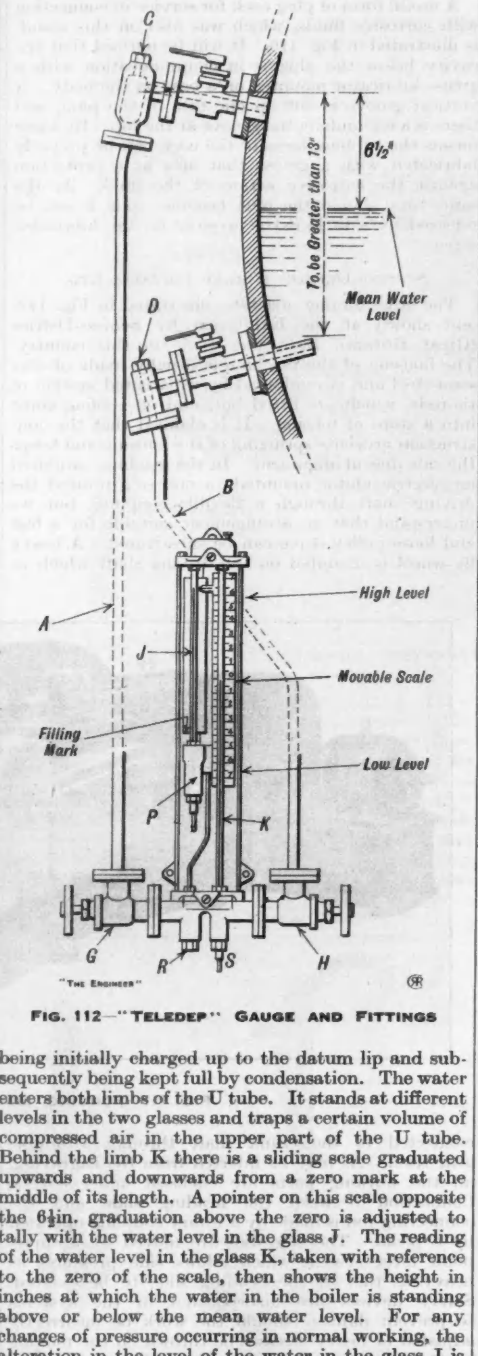

Fig. 112—"Teledep" Gauge and Fittings

A modified arrangement is provided to permit the gauge to be mounted above the level of the boiler.

Bradley and Foster, Ltd.

For those to whom cast iron is just cast iron and nothing more, a visit to the stand taken by Bradley and Foster, Ltd., of Darlaston, must have been of great interest. The exhibits consisted of a very wide range of refined pig irons with a bewildering variety of compositions, suitable for producing cast irons with various properties. One of the most interesting exhibits was a complete range of fractures of malleable pig iron designed to show the regular practice of the firm in grading into ten fractures. There can be little doubt that were some such standard system adopted universally producers of pig irons would benefit considerably. Another range of irons—blended all-mine pig—is produced by the firm in a range of compositions to suit individual requirements. The range is the outcome of extensive investigations carried out with the object of matching the properties of cold blast, Swedish, and charcoal irons, and the makers now claim that they have devised means of blending together suitable materials to match exactly the specific properties of the various cold blast and charcoal irons examined. Of particular interest to foundrymen who receive inquiries for castings of special composition, or to specified mechanical tests, were the alloy irons exhibited, many of them for the first time. The qualities ranged from low nickel-chrome irons for direct use up to various types of austenitic ingots. The variety of pig irons was so wide that it is quite impossible here to mention everything.

Loranco Ltd.

The stand of Loranco Ltd., 38, Sydenham-road, London, S.E.26, was principally devoted to small tools of foreign origin, and among them there were several of notable interest. There was, for instance, a light sensitive drilling machine driven by its own electric motor, through a belt and an automatic clutch. This clutch is brought into operation by the engagement of a spline on the drill shaft when the feed lever is pulled down, so that the motor and belt may be running continuously, but the drill spindle only starts to move when the feed is put on; the clutch slips if the feed is so gross as to endanger the drill. There were also on this stand some very high-speed rotary tools—see Fig. 113—for speeds up to 100,000 revolutions per minute. These tools are driven by little air turbines working at pressures of from 30 lb. to 100 lb. per square inch, and are notable on account of their lack of vibration. The air consumption is from 7 to 10 cubic feet per minute. With the help of a small pencil-shaped abrasive

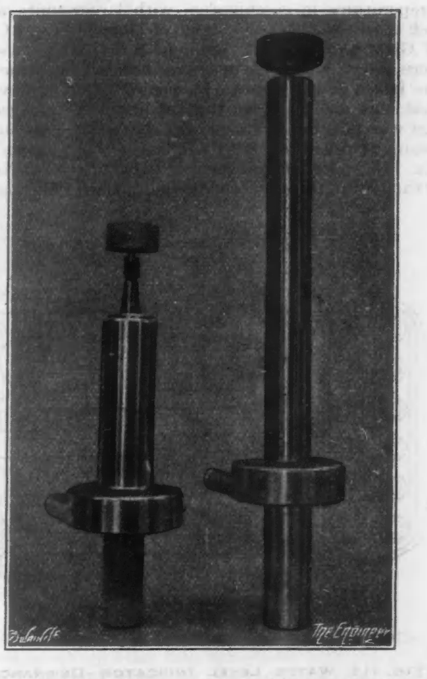

Fig. 113—High-Speed Rotary Tools—Loranco

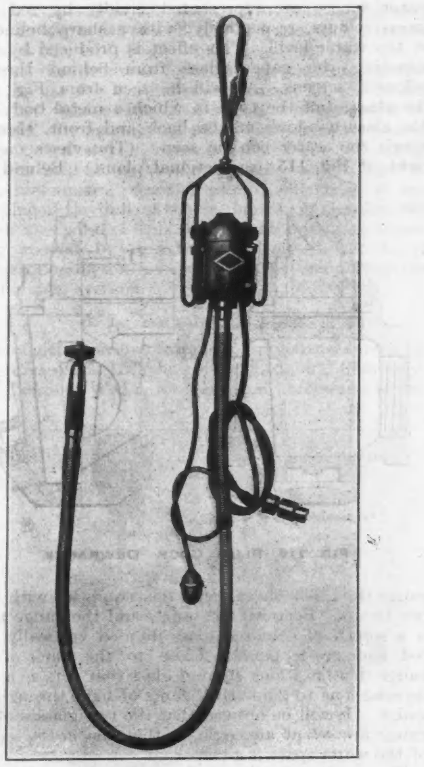

Fig. 114—¼ H.P. Flexible Shaft Outfit—Loranco

cutter we found it quite convenient to write script on a piece of plate glass.

There was also a little high-speed flexible shaft outfit, as shown in Fig. 114, for electric drives. It has a ¼ horse-power motor running at a speed of 10,000 revolutions per minute, and will operate a 2in. by ½in. grinding wheel. The flexible shaft has an inner core 10 mm. in diameter by 4ft. long, which floats in the motor shaft as it is bent. The outer casing is screwed directly on to the motor frame. The chuck runs on double ball bearings and takes tools with 6 mm. shanks.

Dewrance and Co.

The trend towards higher steam pressures and temperatures in combination with larger units was well exemplified on the stand of Dewrance and Co., of Great Dover-street, London, S.E.1, where there were shown a number of valves ordered for some of the latest power plants. It seemed to us, however, that this change from the conditions of a decade ago was best demonstrated by the water level indicator, of which the essential features are shown in Fig. 115, and which was referred to in our issue of Nov. 11th, 1932. In other words, the modern boiler is of such great dimensions and the water level gauge is so far above the floor that it is unreadable directly. The reading must consequently be transmitted to a more convenient height for ordinary operation. In the Dewrance apparatus the transmission is effected optically, with the consequence that there is no friction or lost motion.

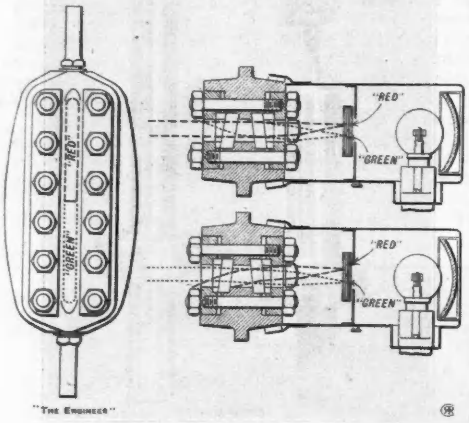

Fig. 115—Water Level Indicator—Dewrance

A system of reflectors is used to bring the image of the gauge glass to a convenient level, but instead of showing a plain view of the water level, the steam and water spaces are represented vividly by red and green colours, respectively, with a sharp boundary at the water level. This effect is produced by illuminating the gauge glass from behind through coloured screens. As will be seen from Fig. 115, the glass is of the type in which a metal body has flat glass windows at the back and front, through which the water can be seen. (The views on the right of Fig. 115 are sectional plans.) Behind the gauge there is a sheet metal box equipped with electric lamps. Between the lamps and the gauge there is a screen of coloured glass divided vertically into red and green panels. Close to the back of the gauge there is a long strip of glass that acts as a condensing lens to guide the beams of light through the gauge. It will be noticed that the two glasses of the gauge are set at an angle, so that the cross section of the water space is a trapezoid.

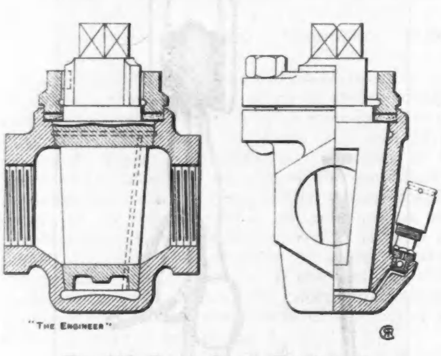

Fig. 116—Plug Cock—Dewrance

The result, according to the makers, is as follows :—Beams of red and green light are projected through the strip lens and strike the face of the glass plate at different angles, each being refracted. When the space between the glasses is occupied by steam the refractive index is such that the green beam of light is bent, so that it strikes the inside of the body of the gauge and does not emerge, whereas the red beam is so bent that it passes right through the gauge into the line of sight of the observer, who then sees a "red glass." These conditions are shown in the upper section. When the space between the glasses is occupied by water, however, the refractive index is such that the red beam of light is so bent that it strikes the inside of the body of the gauge and is lost, whereas the green beam is bent into the line of sight of the observer, who sees a "green glass." These conditions are shown in the lower section. Thus, it will be appreciated, the device illuminates the sight glass of the gauge in two colours—green for the water and red for the steam, and as the water level changes so the colours change, and the level can be clearly seen by the boiler attendant in the mirror below.

A useful form of plug cock for service in connection with corrosive fluids, which was also on this stand, is illustrated in Fig. 116. It will be noticed that the cavity below the plug is in communication with a grease lubricator mounted on a boss on the body. A vertical groove is cut up one face of the plug, and there is a circumferential groove at the top. By these means the rubbing faces of the cock can be properly lubricated with a grease that acts as a protection against the corrosive action of the fluid. At the same time should the plug become stuck it can be released by a little extra pressure on the lubricator screw.

Schiess-Defries (Great Britain), Ltd.

The large forging machine illustrated in Fig. 117, and shown at the Exhibition by Schiess-Defries (Great Britain), Ltd., was made in this country. The housing of the machine is usually made of cast semi-steel and is reinforced by a patented system of tie-rods, which are fitted hot, and on cooling come into a state of tension. It is claimed that the construction prevents springing of the housing and keeps the side dies in alignment. In the machine exhibited an electric motor mounted to one side rotated the driving shaft through a flexible coupling, but we understand that an arrangement suitable for a fast and loose pulley drive can be substituted. A heavy fly-wheel is mounted on the driving shaft which is, connected to the crank shaft through a double gear train. As may be inferred from the engraving, all the working parts are enclosed under covers. Connection between the heading slide and the connecting-rod is made by a rotary coupling operated by a pedal. The side dies are moved by a three-point lever system which allows side pressures as heavy as that of the heading slide to be exerted. Safety devices are incorporated in the systems to prevent damage should the work be incorrectly adjusted or heavy stresses be thrown on the moving parts by other means. An adjustable stop enabling the operator to insert the correct length of material is fitted. Some dimensions and other figures are given in the following table :—

End pressure ..	180 tons	Width of dies ..	130 mm.
Die opening ..	85 mm.	Stroke of dies ..	200 mm.
Height of dies ..	330 mm.	Strokes per minute	60
Length of dies ..	330 mm.	Power required ..	15 H.P.

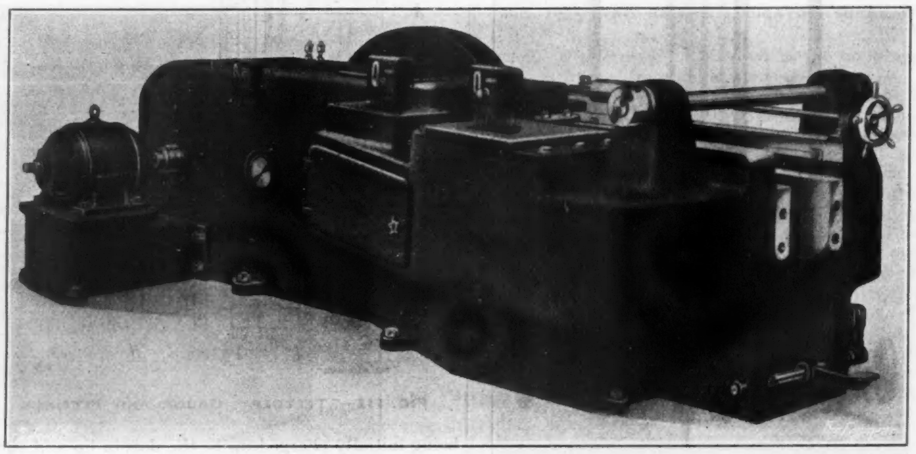

Fig. 117—Forging Machine—Schiess-Defries

Henry Hughes and Son, Ltd.

Navigational instruments of various kinds were shown by Henry Hughes and Son, Ltd., of 59, Fenchurch-street, E.C.3. One of the most interesting exhibits was the British Admiralty Magneto-striction apparatus, which may be provided with a recorder or dial, and which enables soundings to be recorded continuously and silently in any weather. The sound is produced by the vibration of a nickel magneto-strictive unit mounted in a small chamber within the ship. After passing through the ship's plating, the sound is reflected from the sea bed, and is received by a second magneto-strictive unit, which enables the time interval to be recorded on the wheel-house instrument from which the depth is read. Examples of typical installations were shown ranging from a portable outfit for river and harbour survey work, as illustrated with the case removed in Fig. 118, to the oceanic pattern in which the depth range is split up into sections by a system of phasing which allows an open scale to be used throughout the range. The oceanic recorder shown was, in general, similar to the Challenger instrument, and suitable for a range of 6000 fathoms. The scale of the record of the shallow water apparatus is 35 fathoms, or 7 fathoms per inch, with lines on the chart at every 5 fathoms, the accuracy being within 1ft.

Another equipment for merchant vessels, trawlers, and sloops has a 90-fathom scale, or 18 per inch, the range being 250 fathoms in four phases. Since the whole width of the chart is available for each section, the scale obtainable is very much larger than it would be if the whole range was represented at one time. An apparatus shown for high-speed vessels has a scale record of 142 fathoms, or 28 fathoms per inch, with a range up to 1200 fathoms, whilst a boat survey apparatus for motor craft has a scale record of 125ft., or 32ft. per inch.

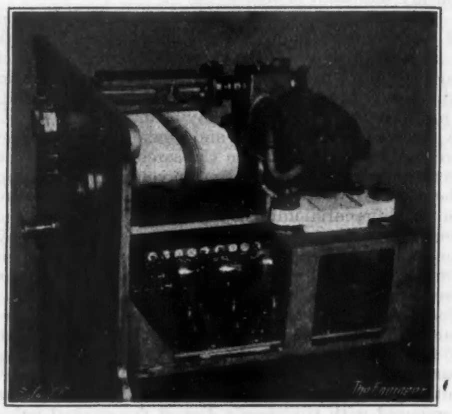

Fig. 118—Echo Sounding Recorder—Hughes

Other notable exhibits consisted of the "Husun" dead-beat compass; the Gothic micrometer sextant, with detachable bubble horizon; special-purpose sextants, and the Holmes magnetic compass with repeaters.

Kitson Pump Sales and Engineering Company.

The pumps that were to be seen on the stand taken by Kitson Pump Sales and Engineering Company, of 25, Victoria-street, Westminster, were all of the rotary type with moving blades. In Fig. 119 a photograph of a small pump of the firm's manufacture, with the barrel partly withdrawn to indicate its construction, is reproduced. There are only three moving parts, the rotor and two solid blades. The curve of the bore of the casing, the makers informed us, is so worked out that the blades

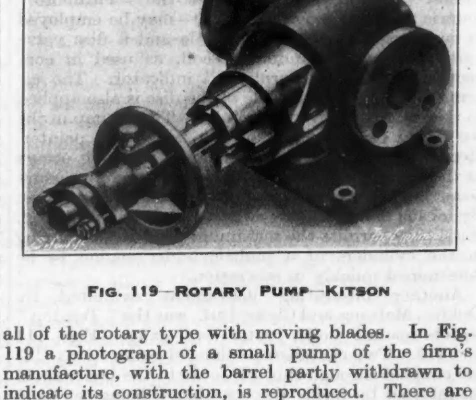

Fig. 119—Rotary Pump—Kitson

are guided into and out of the rotor slot at constant acceleration. As the blades are solid they are not pressed by springs or by any other means against the casing, which thus has a purely guiding action upon them. Hand pumps are made for capacities of 250 and 650 gallons per hour approximately against 60ft. head, and power-driven pumps in a range covering deliveries from 750 to 30,000 gallons per hour against heads of 75ft. to 150ft.

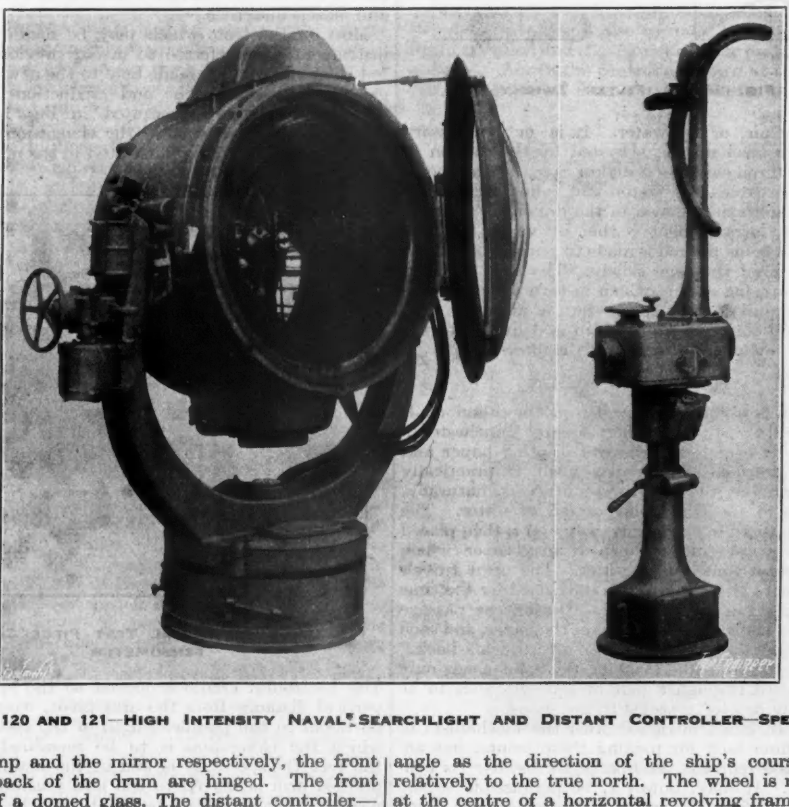
Captain Russell

With the increasing use of aluminium alloys in the construction of oil engines for electrical conductors and apparatus, and for light constructional parts generally, the necessity for turning the metal is frequently encountered. There was shown at Olympia, on the stand of Captain S. P. B. Russell, of Silverthorne, London-road, Camberley, a new "Alumalloy" tinning fluid, the use of which was successfully demonstrated in our presence, on rolled sheets and cast vessels. The results obtained appeared to be satisfactory as regards the interpenetration of the two metals, and where desired, tinman's solder was freely used once the metal was tinned. The covering capacity of the fluid is stated to be very large. The fluid is employed for the preparation of aluminium alloy connecting-rods and bearing shells for white metalling, while another use is for giving a protective coating of tin, in the case of aluminium alloy parts which are exposed to the action of sea water. With polished metal the use of a tinning fluid enables the parts to be chromium-plated.

On the same stand there was demonstrated an aluminium solder, which is used for filling up blowholes in castings, the repair of cracked castings, and the building up of lugs. It is known as "Alumalloy" semi-weld solder, and would seem to form a useful material for facilitating light metal construction and its repair.

The Sperry Gyroscope Company, Ltd.

A notable exhibit on the stand of the Sperry Gyroscope Company, Ltd., was the 36in. distant-controlled, high-intensity searchlight illustrated in Fig. 120. This searchlight is a naval pattern, and was constructed for a Portuguese sloop. It has a beam of 350 to 400 million candle-power intensity, and is constructed of a non-corrodible aluminium alloy. Its weight is only 1550 lb. Its range of movement extends from 100 deg. above to 20 deg. below the horizontal. The iris shutter, capable of being closed down to zero aperture, can be operated either by hand from a station at the searchlight itself, or electrically from the distant controller. The arc lamp is automatic in action, being fitted, to that end, with a thermostatic control. To give ready access to the lamp and the mirror respectively, the front and the back of the drum are hinged. The front consists of a domed glass. The distant controller—Fig. 121—is provided with two handles, one for elevating the searchlight, and the other for moving it in azimuth. The transmission from the controller to the searchlight is effected by a step-by-step electrical system, which ensures the immediate cessation of the movement of the projector simultaneously with the cessation of the movement of the control handle. A pair of binoculars mounted on the controller at a height adjustable to suit the stature of the operator, move in azimuth and in elevation in exact relationship with the movement of the searchlight beam.



Figs. 120 and 121—High Intensity Naval Searchlight and Distant Controller—Sperry

Among the other exhibits on the company's stand was an improved pattern of the Sperry-Villiers "Odograph." This instrument records to scale on a chart the actual course followed by a ship. The direction of the course plotted on the chart is controlled by impulses received at the instrument from the gyro-compass repeater transmission system, while the distance run is governed by impulses received from an electrical ship's log. In the original design of the instrument—illustrated herewith in Fig. 122—the chart is mounted on an iron-covered table, and over it there moves a wheel magnetised to adhere to the iron surface. This wheel is rotated on its axle by the impulses from the electrical log at a speed proportional to the ship's speed. At the same time it is controlled by the gyro-compass to turn about its vertical diametral axis. This control is such that the wheel is constrained to set its plane, relatively to the ship's longitudinal central plane, at the same angle as the direction of the ship's course bears relatively to the true north. The wheel is mounted at the centre of a horizontal revolving frame which is free to turn in azimuth with the wheel. This frame carries a pointer which reads against an external ring marked with the points of a compass card or in degrees. The north point of this external ring is constrained to tally with the north of the chart by means of a set of jointed parallel arms, clamped to the edge of the chart board, after the manner rendered familiar by the drawing office "drafting machine." The instrument as a whole is supported by a carriage mounted on castors. An arm, adjustable as regards direction, is clamped to the carriage, and on it a pencil carrier can be fixed at any desired point. The carriage, it will be gathered, is, by virtue of its attachment to the board by the jointed parallel arms, free to move to any point on the chart, the only constraint imposed upon it being that whereby the north point of its graduated ring is caused to tally at all positions of the instrument on the chart with the north of the chart. The movement of the carriage is governed by the movement, azimuthal and rotational, of the magnetised wheel within it. Initially, the direction of the magnetised wheel is set by hand into agreement with the ship's true course as given by the gyro-compass. This setting will be correct when the index on the frame surrounding and moving in azimuth with the magnetised wheel indicates the true course against the graduated ring. The pencil arm and carrier are simultaneously adjusted to bring the pencil point over the ship's position on the chart. Thereafter, the instrument will proceed to plot the ship's course without farther adjustment or attention. Provision is made whereby the operation of a drum divided to show inches to the mile enables the speed of rotation of the magnetised wheel on its axle to be varied to suit the scale of the chart. Provision is similarly made to allow for the change of scale with latitude in ocean charts.

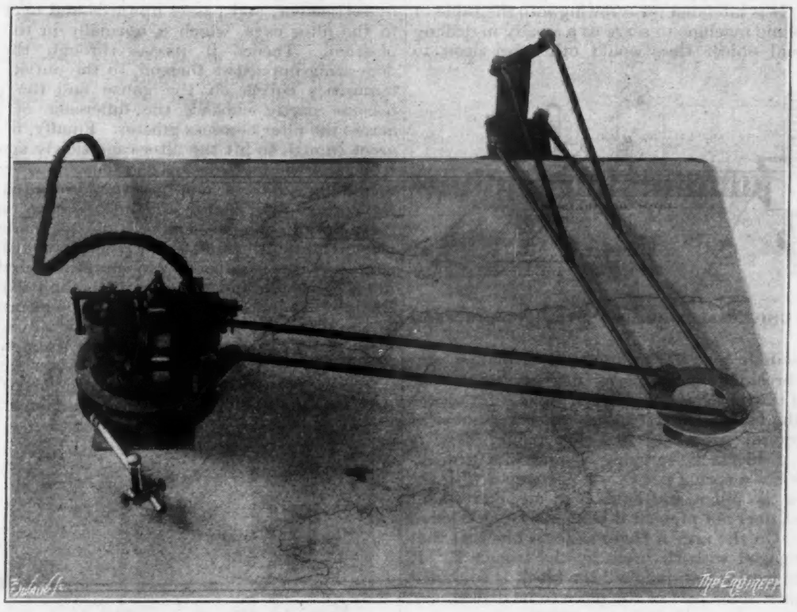


Fig. 122—Sperry-Villiers "Odograph"

This, the original, form of the instrument has been in use for a number of years. In the newer form, the first example of which was exhibited at Olympia, the magnetised wheel and an iron-surfaced chart board are dispensed with. The operating wheel is held down to the chart by weight instead of by magnetism. Another alteration consists in the grouping of the bulk of the mechanism at the clamped end of the parallel arm system, the operating wheel being moved by impulses transmitted out to it through conductors inside the tubes composing the parallel arm system.

E. L. Youngleson, Ltd.

Among the various workshop appliances shown on the stand of E. L. Youngleson, Ltd., 67, Chancery-lane, London, W.C.2, we were again attracted to the merits of the universal vice, of which we gave some description in our issue of May 12th, 1933. It will be remembered that this vice has the peculiarity that the front jaw is divided into two pieces, each of which is mounted on a swivelling stalk, so that the gripping faces may accommodate themselves to the object

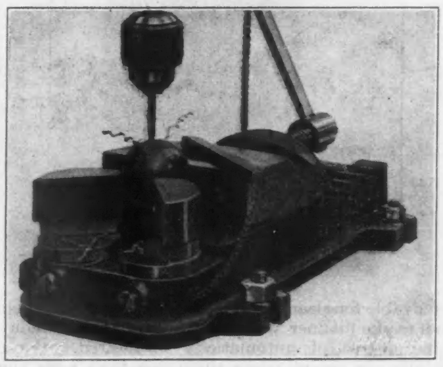

Fig. 123—Machine Vice—Youngleson

to be held. We gave this vice somewhat of a test in holding an old half-penny—it was of Victorian mintage, and consequently had a rounded edge. The vice held it so securely that we were able to file off the minting impression without the coin once jumping out.

There was also a recent development of the same vice for machine table service, of which we give an illustration in Fig. 123, which shows how it is adapted for bolting down to the table. It should prove very useful in many tool-room jobs.

A handy little gadget on this stand was the universal drilling stop, represented by the sketch, Fig. 124. It is intended for screwing into the table of a light drilling machine to serve as a steady in drilling some casual object that would otherwise need to be held securely by hand to prevent it wobbling, and possibly breaking the drill as it emerged at the bottom of the hole. It comprises a pillar A for screwing into the table, which is turned with a number of circumferential grooves. On this pillar there is mounted a block B carrying a rack-like arm F. The block has a spring peg C, which engages with the grooves in the pillar, and holds it at any convenient height, but does not prevent it being raised or lowered by hand. On the arm F there slides a block D that can be engaged with the rack by the trigger E. It is a simple matter to "juggle" the block D so that it bears against some part of the piece to be drilled, and thus prevents its accidental movement.

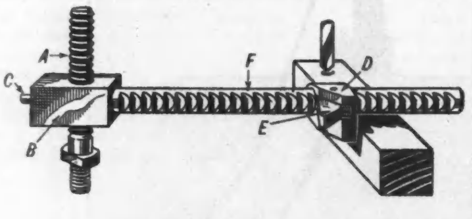

Fig. 124—Universal Drilling Stop—Youngleson

Zwicky, Ltd.

As engineers produce mechanisms to closer and closer tolerances, and to work with finer and finer clearances, the importance of the suitable filtration of oils, both lubricating and fuel, and other liquids becomes greater. This matter breeds problems of its own, for while in the days when only comparatively coarse filtration was required, a filter that was removable for cleansing by hand in a somewhat rough and ready manner was no disadvantage, nowadays some degree of automaticity is desired. Consequently, in recent years there has been very considerable development of semi-automatic and completely automatic self-cleaning filters. One of the most ingenious and effective of these devices was to be seen on the stand of Zwicky, Ltd., of Slough, and is illustrated in the line and tone engravings, Figs. 125 and 126. Use, in this filter, is made of the increased pressure difference brought about by the collection of impurities in the gauze to cause the mechanism to operate and set in action for a short interval a reverse flow. For this purpose the filter gauze cage D is mounted on a vertical rod having axial movement. A spring toggle gear acts on this rod. In the engraving it occupies its top position, and it will be seen that the springs of the toggle gear tend to retain it in that position. The arrangement is such, however, that in the bottom position the toggles are inclined at an angle slightly below the horizontal and therefore tend to retain the cage in that position also. Stability, in fact, is only obtained when the cage is in either its top or its bottom position. Entering the inlet chamber through the pipe A the liquid, owing to the sudden enlargement, deposits its grosser impurities by settlement, and passes upwards and over a baffle to the filter cage, which is normally in the bottom position. Thence it passes through the gauze, depositing impurities thereon, to the outlet. As the impurities collect on the gauze and the passages become partly choked, the difference of pressure across the filter becomes greater. Finally, it becomes great enough to lift the filter cage slowly against the springs of the toggle gear. As soon, however, as the toggle limbs have swung past the horizontal position the springs take charge and lift the cage rapidly to its top position. This action, while not hindering the general flow of the fluid through the apparatus, causes a temporary reversal of flow to occur through the gauze filter. Dirt is swept off, past the baffle valve B, into the internal chamber C, whence on the return motion of the filter cage it passes through a valve into the main sump for removal at intervals through a drain plug or cock.

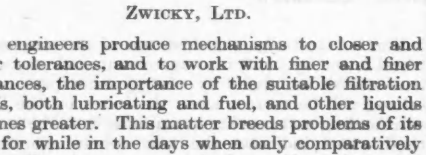

Fig. 125—Oil Filter—Zwicky

The resetting of the filter cage in the lower position may be performed by hand, by a mechanical gear, by steam, by air, or by water. It is only necessary to arrange mechanisms, actuated by the motion of the vertical rod carrying the filter cage, for the operation of the valves of a piston and cylinder construction similar to that shown in the drawing. Perhaps the neatest arrangement is that by which the flow of the fluid being filtered is made to generate sufficient power to reset the cage slowly. The fluid drives a rotor E carrying a cam, which in turn drives a little plunger pump with a spring return motion. This little pump compresses air which is delivered to the "return" cylinder on the top of the filter casing.

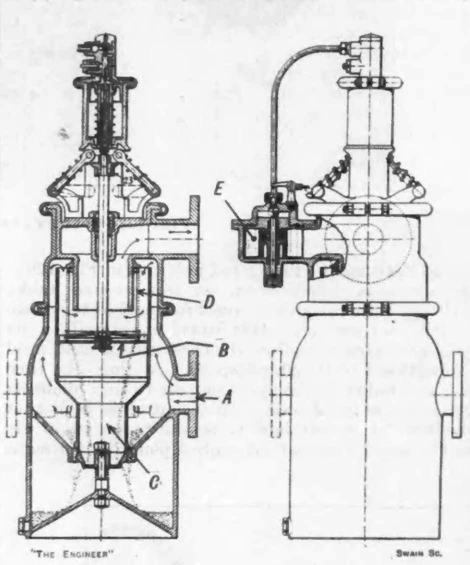

Fig. 126—Oil Filter—Zwicky

J. Halden and Co., Ltd.

There was a distinct novelty on the stand of J. Halden and Co., Ltd., 8, Albert-square, Manchester,2. in the form of a ferro-prussiate printing paper and printing process. The paper itself is practically waterproof, but the sensitised surface is, naturally, amenable to the developing action of water. The paper is printed in the normal way and is then placed face downwards on a sheet of glass over which there flows a thin film of water. The print travels forward with the water and is developed by the time it has passed across the glass. During the passage very little water gets on the top of the paper, and such as does trickles off "like water off a duck's back." On emerging from the machine the print needs only to be passed through a pair of squeegee rolls to be sufficiently dry to be issued to the shops.

We were much intrigued with the mechanism of the machine used for making these prints, but are not, at the moment, at liberty to disclose its construction. It may, however, be permissible to say that the surface formation of the glass over which the water and the print pass is of considerable importance.

Another machine on this stand which, in essence, involves the same principle of avoiding the unnecessary moistening of the fibres of the printing paper is the Dynalator, for making dye-line prints. It is little more than a trough, into which there dips a roll of stainless steel. Above there are two rubber-coated rolls. The exposed print is passed between these rolls and picks up, from the stainless roll, just sufficient of the developer to make a good print. The machine is arranged either for a simple hand drive, on the end of the main roll, for occasional use, or for an electrical drive for continuous service.

Tensometer, Ltd.

On the stand of Tensometer, Ltd., of 73, Southampton-row, London, W.C.1, there was shown a complete range of the Hounsfield tensometer, which was fully described and illustrated in our issue of February 17th last.

The full range of test pieces which have now been standardised includes eight different test specimens, embracing five different cross sections, which vary from one-hundredth to one-seventh of an inch in area. These, it is claimed, provide a suitable range for tensile tests from 200 tons per square inch downwards. The elongation is measured over the heads, and therefore the parallel length between fillets has a standard ratio to diameter of 3·544, with the exception of two special test pieces used for cast aluminium and plastic materials.

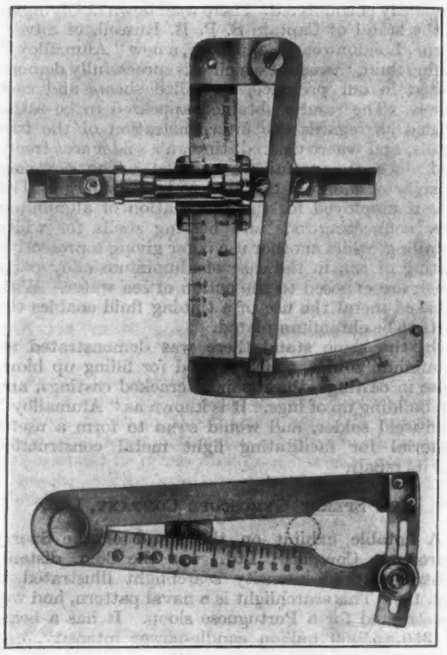

Fig. 127—Elongation and Reduction Gauges—Tensometer

Most of the tests which may be made with the instrument were referred to in our previous article, but reference may be made here to the new universal gauges for elongation and reduction in area per cent. which are illustrated in Fig. 127. The former is designed to show the elongation per cent. of all test pieces and is illustrated in the upper view.

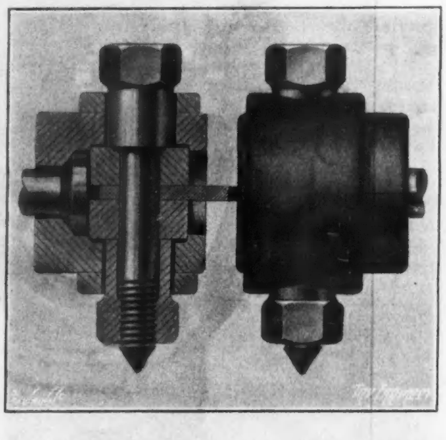

Fig. 128—Sheet Metal Test-Piece Chucks—Tensometer

The horizontal cradle is locked at the appropriate vertical distance from the arm pivot, which is proportional to the parallel length of the test piece on which the elongation is to be measured. Before the test the specimen is laid in the cradle and the pivoted arm is moved to the left, pushing the test piece and left-hand slide before it until the arm reads zero. The left-hand slide is then locked, and after pulling the specimen the two ends of the broken test piece are lightly pressed against the left-hand slide stop by the arm, whose new reading is the elongation per cent.

The reduction in area gauge illustrated in the lower part of Fig. 127 is also a universal gauge, and applies to all test pieces. Before test the unbroken specimen is placed at the zero reading indicated by the dotted circle, and the two arms are closed to touch it, and are then locked. After the test a broken end is slid towards the pivot and the reading at which both arms touch it is the reduction in area per cent. Illustration Fig. 128 shows the very simple form of split chuck with embracing collars and screws, which is utilised for pulling the strip test specimen in a similar way to the tensile test. In order to prevent any previous work hardening of the piece which might take place through punching out the specimen, drilling and filing jigs are provided. The firm has also introduced a simple hatchet form of planimeter for rapidly determining the impact value from the diagram of the notched bar test.

Alfa-Laval Company, Ltd.

A very necessary part of the equipment of the modern liner and motor ship is the centrifugal oil purifier, which also finds a place in many oil engine and power station equipments. On the stand of the Alfa-Laval Company, Ltd., of 34, Millbank, London, S.W.1, there was shown a very complete range of centrifugal oil purifiers. Interest was attached principally to the company's new marine type purifier, which is illustrated in Fig. 129 herewith. While retaining some of the features of the original de Laval, many improvements, based on long service results, have been embodied in the new design. These include new features to increase the self-cleaning properties of the bowl, which can now be sludged out with a flow of water and run dry. The renewable wearing parts of the spindle have been reduced to four, and the spindle is lubricated by a hand-operated pump. Fig. 129 shows a direct-coupled motor-driven machine, but totally enclosed motor-driven machines and belt-driven machines can also be supplied. The international character of the Alfa-Laval company's business and its after-sales service organisation in the principal world ports are factors of considerable importance to shipowners and marine engineers.

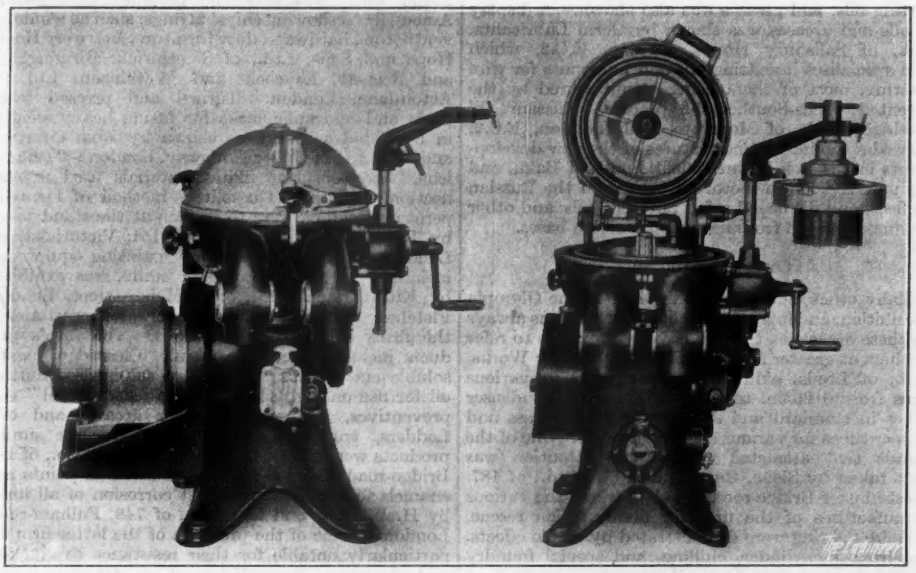

FIG. 129—MARINE TYPE OIL PURIFIER—ALFA-LAVAL

Alexander Stephen and Sons, Ltd.

One of the principal exhibits on the stand of Alexander Stephen and Sons, Ltd., of Linthouse, Glasgow, was a model of the new Stephen three-cylinder compound marine steam engine, which has been designed and built by the company to embody the results obtained from the engines of the s.s. "Annan," which were described in our issue of August 19th, 1932. The high-pressure cylinder valves are of Andrews and Cameron design, and are hydraulically operated, while the two low-pressure cylinders are of the uniflow type. The saving in weight and length of the engine compared with the standard triple-expansion design is, we are given to understand, about 20 per cent. The first engine of this type is now erected and about to undergo exhaustive tests.

George Kent, Ltd.

The principal exhibit of George Kent, Ltd., of Biscot-road Works, Luton, Beds., was automatic boiler control apparatus, arranged on panels to give a clear idea of the nucleus of the two systems which the firm has developed. The Kent electrical system is most suitable for generating station steam-raising plant and large water-tube boilers generally, whilst the firm's hydraulic system is applicable to all industrial boiler plants, and especially batteries of Lancashire boilers. In the master controller of the electrical system, the "gradient analysing" type of control is applied to the balancing of the load with the heat input to the boilers. The steam pressure is measured by a continuously rotating piston which has the pressure applied to its underside through an oil seal. Most of the force is balanced by the deadweight, and light springs make it take up a position proportional to the pressure. The sensitivity is in the neighbourhood of one-tenth of 1 lb. per square inch at 400 lb. per square inch, and the total range of movement can be made to correspond to a variation of only plus or minus 5 lb. per square inch. The movements of the piston are conveyed to two contact arms, one of which receives the motion directly and the other through a friction clutch. Secondary contact arms approach the primary arms at suitable speed and give a length and direction of contact with each primary arm depending on its distance from its central or normal position. The directly coupled arm therefore gives signals depending on the deviation from the correct pressure, while the indirectly fixed arm, which is pushed to the centre at each cycle by the contacts, gives signals depending on the amount by which the pressure has changed since the last cycle, or on the rate of change of pressure.

The profile of the cams which move the secondary arms determines the curve relating the return of the pressure to the correct value, and an adjustment is provided by which the steepness of the curve can be set to suit any installation or condition. The complete installation also includes the furnace pressure controller, and the regulating gear for the draught and fuel. Above the controller shown at the Exhibition, there was an illuminated indicator to show the way the controller was influencing the factors governing the rate of evaporation. Embodied in a panel adjacent to the one for the electrical system was the master controller for the Kent hydraulic boiler control system, which is of simpler construction, and, as we have said, more applicable to industrial boiler plants.

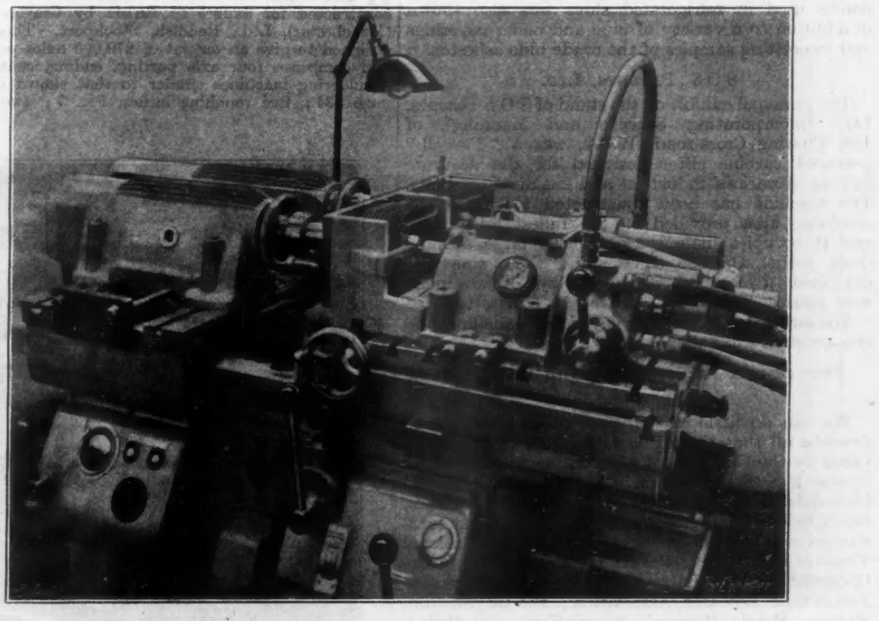

FIG. 130—VOMAG TWO-SPINDLE PRECISION TURNING AND BORING MACHINE

Another exhibit was the fuel air ratio controller, employed to measure the air supply and to adjust the fuel feed accordingly. There was also a model of an air duct containing a damper and operated by a power cylinder, controlled through its distributing valve from the master controller on the panel. Such a power cylinder used with the hydraulic system can either be employed to adjust the position of dampers or to move brush shafting gear on A.C. commutator motors driving fans.

Machine Tools.

There was as usual a fine display of machine tools, mostly of foreign origin, arranged in the annexe to the main hall. The exhibits of Selson, Ltd., and Schiess-Defries (Great Britain), Ltd., have already been described. Other firms showing machine tools were E. H. Jones (Machine Tools), Ltd., of Islington, London; Dowding and Doll, Ltd., Greycoat-street, London; Leo. C. Steinle, Ltd., of 81, Marsham-street, London, and Soag Machine Tools, Ltd., of 45, Horseferry-road, London. Many of the tools on each stand were shown actually in operation, so that visitors could see for themselves the accuracy of the work produced and the methods of operation. Notable on the stand of E. H. Jones, Ltd., were the "Gyromatic" automatic lathes, made by the Tavannes Watch Company, of Switzerland, and described in The Engineer on June 9th last. A Thiel vertical punch and form shaper attracted a good deal of attention. The sketch reproduced herewith in Fig. 131 illustrates the sort of job with which it can deal. In order to obtain the motion the tool holder is mounted on a substantial block forming a sort of crank between two bearings, so that it may be rocked over by a suitable mechanism at the correct point in the stroke. The Werner milling machines on this stand also made a good show.

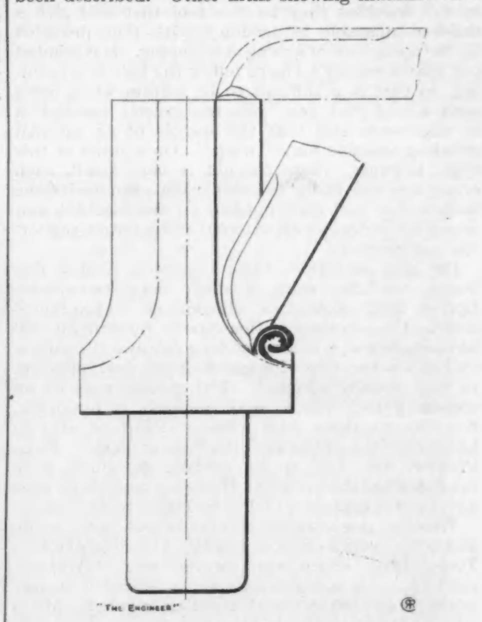

FIG. 131—ACTION OF THIEL SHAPER

A Heller vertical cold sawing machine on the Leo. C. Steinle stand was attractive. It is intended for cutting rolled sections either square or at an angle, and the saw itself is mounted in a cage that may be swung through 360 deg. A flange motor mounted on the saw carriage drives the blade, and the table is in the form of a self-centring vice so arranged that the work is always held under the middle of the saw blade. Longitudinal motion of the table is available for setting the blade to the height of the gripping jaws ready for the cut, and for adjusting the work according to the marking off. The Vomag precision finishing machines, with two and three spindles respectively, exhibited, are intended for use with diamond or tungsten carbide tools upon the finishing of holes. The distance between the spindles is adjustable so that work may, for instance, be carried out simultaneously on the big and little ends of a connecting-rod. The feed is hydraulic. A two-spindle machine is illustrated in Fig. 130. The makers believe that in this machine they have a tool that will give a finish comparable in accuracy with that provided by the operations of honing and lapping. It is pointed out that a reamer tends to follow the hole it is reaming, so that it is difficult to be certain when using such a tool that two holes are exactly parallel or in alignment, and that the spindle of an internal grinding machine may "whip." On a lathe of this type, however, where the cut is very small, such errors are not likely to arise. We examined some bushes that had been finished on the machine and found the surface, both external and internal, mirror-like and accurate.

Dowding and Doll, Ltd., besides a Krause fine boring machine, using a single tungsten-carbide-tipped tool, showed a Magdeburg "Chip-flow" lathe. The principle of this type of machine, it will be remembered, is to arrange for a downward-pointing tool and a direction of rotation of the work opposite to that usually adopted. The spindle runs at an unusually high speed, and the feed is hydraulic. Familiar to those who make a habit of visiting Leipzig are the products of the Pfauter works. Three Pfauter gear and spline hobbing machines were exhibited on the stand at Olympia, and there were also several examples of Pittler lathes to be seen.

Welding machines of several types—spot, seam, and butt—were to be seen exhibited by Soag Machine Tools, Ltd., which also showed some "Wotan" products, a heavy-duty shaper, a precision surface grinder, and an internal grinding machine, all of which were hydraulically operated.

THE CAPE ASBESTOS COMPANY, LTD.

An interesting exhibit on the stand of the Cape Asbestos Company, Ltd., of 26, Holborn, E.C.1, was an electrically heated steam pipe of 4in. bore with a length of 4ft., which was covered with a layer of "Bandall-Caposite" insulation and maintained at an internal temperature of 600 deg. Cent. The outer covering was only warm to the hand, and demonstrated the effective insulation provided by blue Cape asbestos, which, it is claimed, is one-third lighter than magnesia coverings. In collaboration with Donald Bean and Co., Ltd., of Glasgow, an illustration was shown of a ship's cabin which was fitted on the outside with "Bandall" cement-faced blue slabs, and was lined with fireproof plywood panels on the inside, showing the construction adopted for a mid-section of the ship just above the water line, and the method of covering beams and knees, and of giving access to adjoining spaces where necessary. Examples of the special washable panels used in refrigerated ships was also shown in addition to a variety of pipe and boiler coverings and interesting samples of the crude blue asbestos.

S O S PATENTS, LTD.

The principal exhibit on the stand of S O S Patents, Ltd. (incorporating Stevens and Manning), of 156, Charing Cross-road, W.C.2, was a "Pascall" patented turbine sifter designed for the accurate sieving of various industrial and chemical products. The machine has been constructed to utilise the screening area provided to the fullest advantage, and it occupies little space for the large outputs dealt with. On the same stand there was also exhibited a comprehensive display of strainers, wire gauzes, and sieves, as well as a new type of "Artmarble," which is employed for panelling and construction work aboard ship.

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH.

We can do little in the space at our disposal to describe all that there was to be seen on the stand taken by the Department of Scientific and Industrial Research at the Exhibition. Anyone who has had in his hands the annual report of any one of the bodies, listed below, that co-operated to make the stand a success will appreciate our difficulty. The National Physical Laboratory; the Fuel Research Station; the Chemical Research Laboratory; the British Scientific Instrument Research Association; the British Non-Ferrous Metals Research Association; the British Cast Iron Research Association, and the Industrial Research Council of the National Federation of Iron and Steel Manufacturers, all displayed representative objects illustrating the lines upon which their respective works were proceeding. In the circumstances, we do not intend to attempt any description whatever, but only to welcome the enterprise of the research bodies in taking so much space at the Exhibition. In this way many of those who otherwise can only derive their instruction from the printed records of the research work were enabled to see for themselves the actual specimens, models, or graphical conclusions. The stand, indeed, had an atmosphere quite foreign to that of the others. There was about it that air of quiet undisturbed study so noticeable in a laboratory, and imagination almost cheated the visitor into believing that it was quieter there than elsewhere in the Exhibition hall. The attention it received will, we hope, encourage the Department to take space on other occasions.

THE OIL COMPANIES.

At an exhibition in which oil engines played so important a part, it was not surprising to find a good representation of oil-producing interests. On the stand of Shell-Mex and B.P., Ltd., of Shell-Mex House, the Strand, London, W.C.2, were shown samples of their different grades of fuel for internal combustion engines. These included "Shell Diesel Oil," for marine and industrial oil engines; "Gasoleum," for the smaller types of engine, and "Light Diesoleum," for high-speed compression-ignition engines. A wide selection of lubricants, cutting oils, and greases was also shown.—A display of oils and greases was shown by Germ Lubricants, Ltd., of Salisbury House, London, E.C.2, which firm specialises in cutting oils and lubricants for wire drawing, most of them being manufactured by the patented Wells-Southcombe process.—Russian Oil Products, Ltd., of Moorgate Hall, London, E.C.2, showed some interesting pictures of the new developments in the Lok Batan oilfield, South of Baku, and the new 10,000-ton motor oil tankers of the Russian oil fleet, and displayed a full range of oils and other products derived from natural petroleum bases.

OTHER EXHIBITORS.

Many other makers also exhibited at the Olympia Exhibition, and it is a matter of regret to us, as always on these occasions, that we have been unable to refer to them at greater length. Yorkshire Copper Works, Ltd., of Leeds, exhibited copper tubes in various sizes from 0·005in. to 24in. in diameter, condenser tubes in standard and special alloys and brass and copper tubes for various special purposes. One of the stands that attracted considerable attention was that taken by Siebe, Gorman and Co., Ltd., of 187, Westminster Bridge-road, London, where the various manufactures of the firm for diving, mine rescue, and fire fighting were demonstrated by scenic effects. Pig irons in cylinder, chilling, and special foundry qualities were exhibited by British Pigirons, Ltd., of Abbey House, Victoria-street, London, a firm which claims to be a pioneer in Great Britain in the supply of pig iron to a definite guaranteed analysis, coupled with the appropriate fracture. That ingenious instrument, the electro-magnetic crack detector, which we have described on previous occasions, was shown by the Equipment and Engineering Company, Ltd., of 2 and 3, Norfolk-street, Strand, London, and among other firms exhibiting whose products or processes must be familiar to readers of THE ENGINEER were British Dardelet Threadlock, Ltd., of Chase-road, London, whose works we described as recently as August 18th last, and Fescol, Ltd., of 101, Grosvenor-road, London. With so fine a display of oil engines as that at Olympia, it was to be expected that firms such as Wellworthy, Ltd., of Lymington, Hants, and the Clews Petersen Piston Ring and Engineering Company, Ltd., of Mill-lane, West Hampstead, should show their piston rings of various types. Packings of various kinds of "Lion" brand were exhibited by James Walker and Co., Ltd., of Woking, the principal types being "Block Steam," "Expanding Steam," and "Automatic Water," for steam and hydraulic work, "Emerald" packing for expansion glands, and "Sturntite" for propeller shaft glands. Among firms showing ships' fittings, such as windows, ventilators, hardware, door furniture, &c., were Henry Hope and Sons, Ltd., of Smethwick, Birmingham, and Beckett, Laycock and Watkinson, Ltd., of Acton-lane, London. Turned and pressed metal parts and hydraulic jacks for lifting heavy weights in restricted spaces were shown by Ross Courtney and Co., Ltd., of Upper Holloway, London; "Chameleon" oxy-acetylene filling materials used in connection with the "Gussolite" method of low-temperature welding, were to be seen at the stand taken by Thorn and Hoddle, Ltd., of 151, Victoria-street, London; and some neat spray painting equipment, including portable compressor units, was exhibited by Kurt Erlach, Ltd., of 2, Melior-street, London. Fletcher, Miller, Ltd., of Manchester, was among the firms exhibiting special oils. The firm's products include "Cooledge" and "Clearedge" water soluble cutting oils, "Swift," a sulphurised cutting oil for use on high-speed automatics, "Rodol" rust preventives, and various other greases and oils. Ladders, trucks, scaffolding, and various similar products were shown by Drew, Clark and Co., of Lea Bridge-road, London; and specimens of paints and enamels for protection against corrosion of all kinds by H. Windsor and Co., Ltd., of 748, Fulham-road, London. Some of the products of the latter firm are particularly notable for their resistance to cracking and abrasion. Rangefinders of several types and a display of binoculars for all sorts of purposes were shown by Barr and Stroud, Ltd. "Bettaskaf" steel tubular scaffolding was exhibited by Burton, Delingpole and Co., Ltd., of Old Hill, Staffordshire.

Railway Axle Plant for Russia.

AN interesting plant for machining railway carriage and wagon axles on a vast scale has recently been constructed for export to Russia by Craven Brothers (Manchester), Ltd., Reddish, Stockport. This plant is designed to give an output of 270,000 axles per annum, and comprises four axle parting, ending, centring, and shouldering machines similar to that shown in Fig. 6, page 334; five roughing lathes, Fig. 7; two finishing machines, Fig. 8, and four journal grinding machines, Fig. 1. The equipment of these machines embraces many features which have hitherto been mainly used on small automatic machines. These features have been included in order that the machines can be operated by semi-skilled or, possibly, by unskilled workpeople.

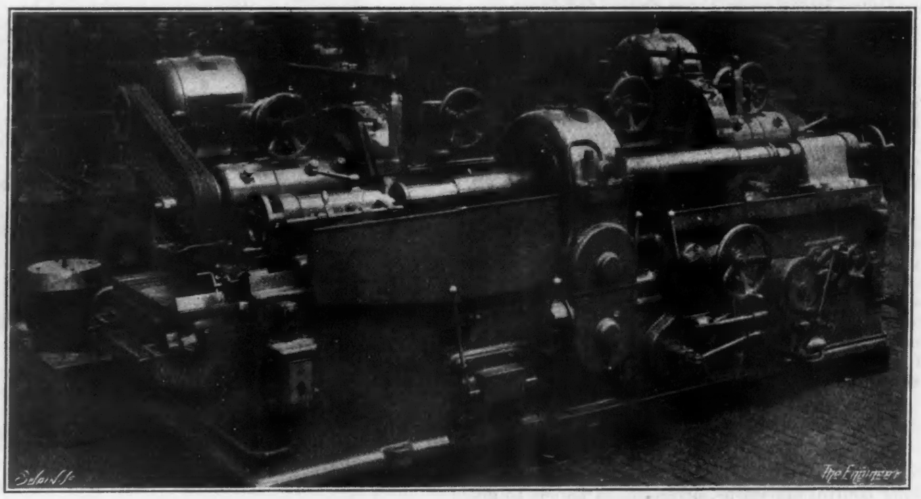

FIG. 1—DOUBLE-ENDED GRINDING MACHINE

The double-ended, centre-driven type of machine tool is specially suited to the machining of railway carriage and wagon axles, and it will be noted that a centre-driven headstock is a feature common to all the machines illustrated. This type of drive for axle lathes is, of course, not new. Applied to machines having multiple tooling and semi-automatic tool slide operation it gives a greatly increased output. The design of the machines has also been influenced by the intention to make use of cemented tungsten carbide cutting tools, which necessitated great strength and rigidity of the parts, and the use of ball and roller bearings and pressure oiling systems to allow of high speeds and maintenance of accuracy of alignment.

PARTING, ENDING, CENTERING, AND SHOULDERING MACHINE.

The parting, ending, centering, and shouldering machine illustrated in Fig. 6 performs the preliminary operations before the axles are placed in the roughing lathe, and although these operations appear at first sight to be simple enough, they involve the use of a number of tools

—see Fig. 2. There are the front and rear parting tools at each end and the tools for cutting out the radiused portion of the journal, mainly to assist in the subsequent machining operations. The operations of drilling and centring the axle are then performed automatically. The sequence of the operations carried out on this machine is as follows:—The axle, being placed in the centre V support, the headstocks with their slides are traversed quickly along the bed, bringing the cutting tools to the correct position for parting the axle. The control for these heads and slide traverse is by means of push-buttons, and the operation of placing the axle on the V supports and adjusting the heads is carried out in approximately two minutes. The jaws of the concentric chucks are then tightened on to the axle also by means of push-buttons.

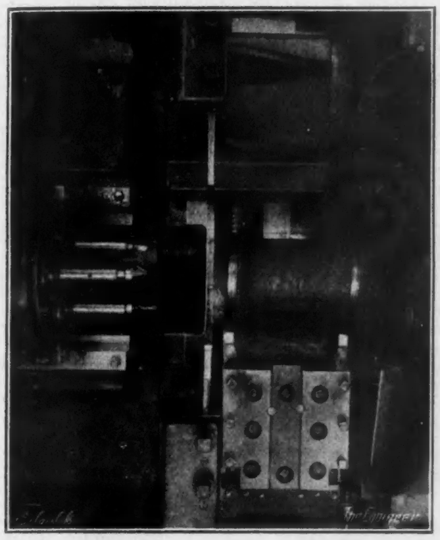

Fig. 2—Tool Lay-Out on Axle Parting Machine

After the axle has been gripped at both ends, a lever centrally placed on the lathe is moved to the starting position, which immediately sets the machine in motion and causes the front and rear tool slides to approach the axle rapidly, after which the feed is automatically engaged. While the ends of the axle are being parted the grooving tools on the front slide are also engaged. These have a traverse of about an inch during the cutting operation, after which they automatically return to the starting position whilst the parting tools continue to traverse. On the completion of the cutting operation the pieces cut from the axle fall into trays provided for the purpose, the tool slides returning automatically to their starting position. It should here be mentioned that during the cutting operation the speed of cutting automatically increases as the tools approach the centre of the work, and during the quick return of the slides the speed automatically changes to the low or starting speed. The main spindle is then stopped by a push-button and the drilling heads, which are also controlled by push-buttons, are set in motion. There are three spindles in a circular form of turret to each tool slide, the first being provided with a cutter which removes the pip left on the axle from the parting operation. This provides the centre for the second spindle which performs the high-speed drilling operation. When the drilling is complete the coning drill spindle comes into operation, finishing the complete centre at both ends of the axle. The drill heads are fed and indexed automatically and when the centering operation is complete they stop automatically.

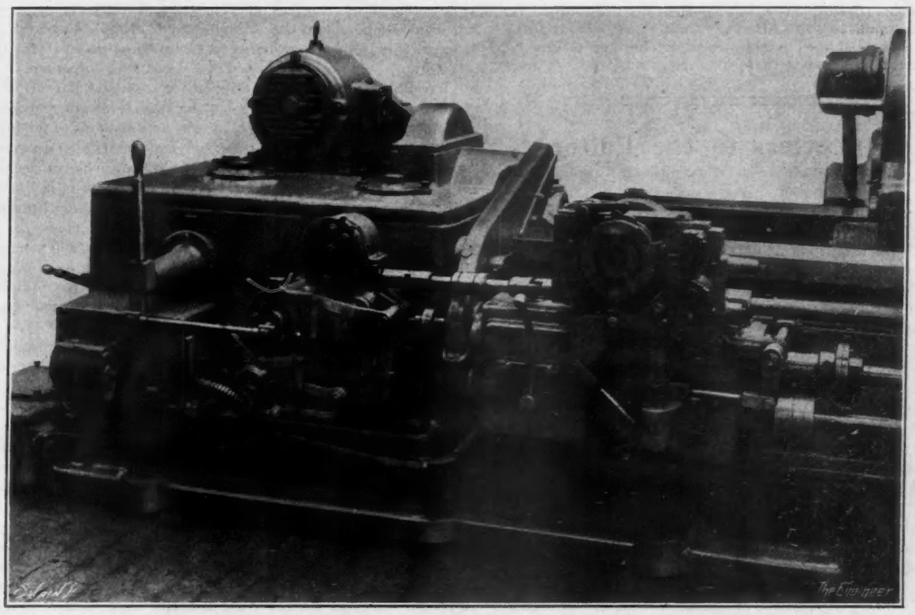

Fig. 3—Tool Slide and Automatic Controls on Parting Machine

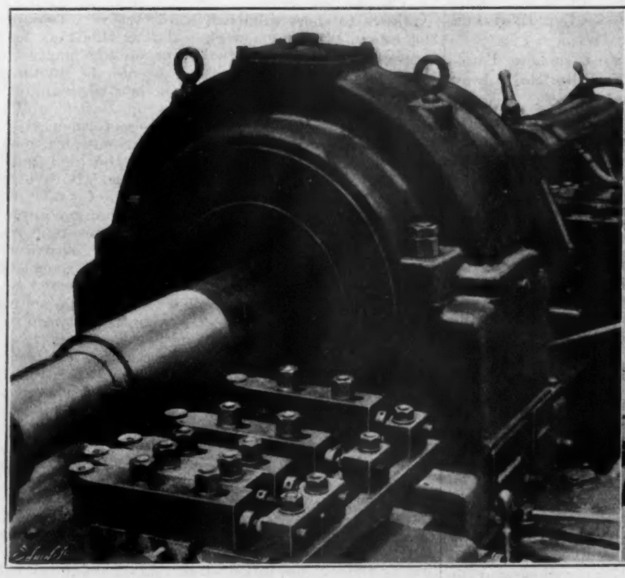

Fig. 4—Tool Lay-Out of Roughing Lathe

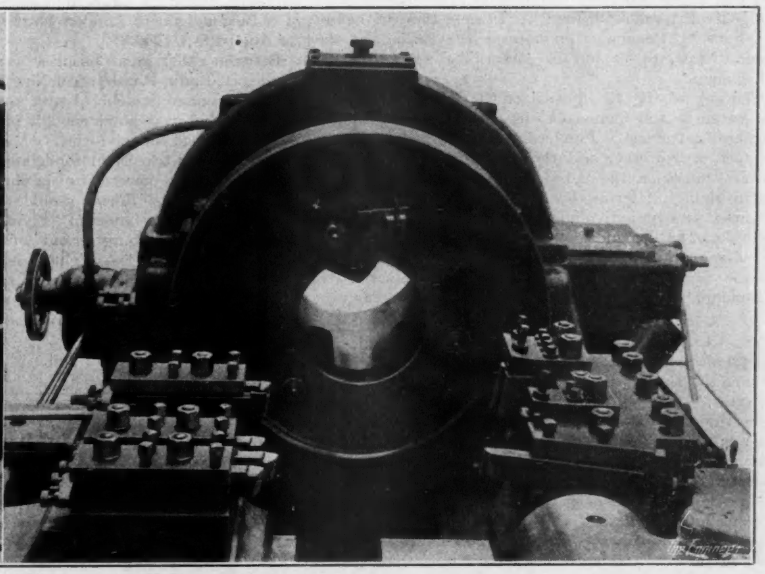

Fig. 5—Tool Lay-Out of Finishing Lathe

The axle is then ready to be released. The chucks are opened by push-buttons, and the headstocks and slides are traversed towards the ends of the bed to enable the axle to be lifted clear. The complete series of operations is effected in eight minutes without any heavy manual effort. There are six electric motors on the lathe, together with the necessary switchgear and control system, and the push-buttons and main control lever are centrally placed for easy access. Fig. 3 shows the controlling mechanism for the automatic operation of the tool slides and the speed change mechanism. It may be mentioned that where it is necessary to use A.C. constant-speed motors, the changes of speed are obtained by friction clutches, but where D.C. supply is available the variations in speed are obtained from a variable-speed motor, the change being adjusted electrically. In both cases the speed changes are controlled automatically by the position of the tool slides. This lathe weighs 19½ tons.

Axle Roughing Lathe.

The axle roughing lathe on which the next series of operations is performed is shown in Fig. 7, and its tool equipment in Fig. 4. The duty of this lathe is to rough turn the journals and wheel seat portion of the axle. The grooves machined during the preliminary operation greatly assist in the adjustment of the tools for depth, so that the longitudinal traverse can start immediately. This lathe is of the semi-automatic type, the tool slide and saddle movements being both automatically controlled from the central control mechanism. Thus when the axle is in position in the machine a lever is moved which causes the tool slides to approach the axle quickly, after which the longitudinal control lever is operated and both saddles and their tools are traversed lengthwise along the axle, turning the various diameters simultaneously. Upon completion of the cut the saddles return to their starting position automatically and the tool slides are rapidly withdrawn from the axle. The tools are all controlled from one central position.

The centre driving spindle is mounted on ball bearings, and the drive from the spindle to the axle consists of a floating type of driver which automatically takes up engagement. The right-hand tail-stock is mounted on a transverse slide, which is provided to enable the axle to be readily passed through the centre head-stock spindle to its correct position. The movement of the tail-stock on its slide is controlled by a push button for rapid adjustment. The tail-stocks are provided with special live centres of heavy design, and the spindle speeds provided enable either ordinary high-speed steel or tungsten carbide tools to be used. The tools are supplied with coolant and all cuttings fall clear into trays below the bed. The main drive is taken by a 60 H.P. motor, and the machine is capable of performing all its turning operations on a 7in. axle in ten minutes "floor to floor" time. Its weight is 14½ tons.

Axle Finishing Machines.

The finish turning operations are performed on the lathe shown in Fig. 8, which is very similar in design to the roughing lathe, except that it has rear tool slides which are automatically operated and are arranged with tools for accurately finishing the shoulders and radii, as seen in Fig. 5. As these tools are never disturbed after being once set up, the accuracy of the various shoulder positions is maintained. The front saddles, provided with tungsten carbide tools for finishing cuts, are entirely independent of the rear in-cutting slides. When once the axle is placed in position and the driver is adjusted the tools are advanced forward to the correct cutting diameter, and the longitudinal feed is engaged. In both saddles this motion is controlled by one lever. A very high cutting speed is obtainable for the use of alloy tools. When the traverse is completed the slides automatically return to the starting position, at which point the operator engages the rear tool traverse mechanism, which causes the tools to approach the axle quickly and automatically, and when the correct depth is attained the feed is automatically engaged. To enable high speed forming tools to be used on the machine after using tungsten carbide tools for the turning operation the speed is automatically reduced, thus mitigating the possibility of damaging the tools by the use of the wrong speeds. When the rear tool-cutting operations are completed the tool slides return automatically to their starting position, during which time the spindle speed is again automatically changed back ready for the first operation. The complete range of operations on this lathe occupies 15 minutes. The machine is driven by a 20 H.P. motor and weighs 12¾ tons.

Grinding Machines.

During the finishing operation material can be left on the journal or wheel seat for a final grinding or burnishing operation, although with tungsten carbide tools the finish obtainable is such that these operations are superfluous. If it is preferred to grind the journals for the "final finish," the double-ended grinding machine shown in Fig. 1 is provided. This machine is also of the centrally controlled semi-automatic type, with two independent grinding heads controlled by one lever at the front of the machine. The grinding heads are provided with hydraulic transverse motion for traversing the grinding wheel quickly to and from the work. Both grinding wheels are mounted on one saddle with longitudinal traverse and operate simultaneously on the journals. An interesting point in this connection is the provision of a traverse mechanism, which enables the complete journal right up to the radii and shoulder of the axle to be ground without any adjustment. The in-feed of the wheels is automatic, and when their work is completed the grinding heads are traversed clear to allow the free positioning of the next axle. The axle is driven from the centre hollow spindle driving head by means of a floating driver, and special micrometer direct-reading caliper gauges are provided at each end of the machine for checking the ground journals. These gauges are always in position, and if it is found that one grinding wheel wears more than the other, resulting in a difference in the diameters of the two journals, a simple correcting adjustment is made. Diamond truing devices are fitted on each tail-stock for imparting the true shape to the wheel. The operations on this machine can be carried out in 12 minutes.

Letters to the Editor.

(We do not hold ourselves responsible for the opinions of our correspondents.)

SCIENCE AND PROGRESS.

Sir,—Your leading article on Sir Josiah Stamp's address, "Must Science Ruin Economic Progress?" is most admirably chosen. For anyone so eminent to suggest that in any circumstances "the world might be better served in the end if scientific innovation were retarded" in any degree at all is indeed ominous. Following closely on the warning to technicians contained in a letter in your previous issue that "they may yet find such activities as the discovery and invention of improved productive processes indicted as criminal offences against the community," these words of Sir Josiah Stamp are strangely like the writing on the wall.

Your are therefore most heartily to be congratulated on taking the stand that "it is not innovation that is at fault, but rather that . . . purchasing power has not advanced *pari passu* with producing power." That, Sir, is a challenge to Sir Josiah's conclusion that there must be "large infusions of social direction" (restriction of scientific innovation?) "and internationalism" (of which the latest example, the world wheat agreement, is a measure for restriction of production to effective demand, *i.e.*, purchasing power). At every stage in the development of Sir Josiah Stamp's most illuminating discourse we find that the dilemma is one of "Money *versus* Man," as Sir Frederick Gowland Hopkins has it, or of "Money *versus* Action." Money, credit, purchasing power; wages, profits; costs, prices; all these are the factors, purely financial, which affect decisions. Occurring repeatedly in nearly every paragraph of his address they point unmistakably to the conclusion which you have drawn.

May I hope, Sir, that you will not weary in well-doing, but will now challenge also the definition of economic progress as "the orderly assimilation of innovation into the general standard of life" for placing the cart before the horse? Economic progress is the raising of the general standard of life in conformity with scientific achievement.

The key to the distribution of the fruits of scientific innovation lies in financial technique, which is simply a matter of arithmetic. Purchasing power is a claim on the product of industry, and the possession of purchasing power confers on the individual that which Sir Josiah Stamp rightly states as the "central feature of economic progress, namely, individual choice of the consumer in the direction of his demands." And that, Sir, is not a question of making gramophones before you can purchase boots. On the contrary, it is simply a matter of arithmetic.

London, September 28th. W. L. Bardsley.

Sir,—In your leading article of September 22nd, you sagely remark on an address to the British Association having the sinister title "Must Science Ruin Economic Progress," that it calls for greater application than even the most attentive can give in the lecture hall. This is the more necessary since the definition with which the discourse opens actually begs the whole question at issue.

"Economic progress," it runs, "is the orderly assimilation of innovation into the general standard of life." That definition, if accepted, is the very charter of those who suggest that technical advance is too rapid, that it must be controlled, retarded, and even discouraged or punished.

Before submitting a definition which is more in accordance with evolution, with human aspiration, and with the very nature of things, please let me call attention to the euphemism for control in the word "orderly," a euphemism which is repeated in the conclusion of the discourse in the phrase "large infusions of social *direction*." Notice also the correspondingly derogatory use of the word "innovation," which conveys the idea "new-fangled" instead of what has been called "the progress of the industrial arts."

A better definition of economic progress may be obtained by reversing the above to read, "the advance in the general standard of life resulting from 'innovation'"; but even that suffers from the same lack of precision as the original, and, as you say in your second leader, "Science" (which need not exclude economic science), "consisting as it does of nothing but precision of observation followed by precision of thought, demands for the communication of its knowledge precision of expression. If it is to survive, let alone progress, it dare not employ loosely defined terms."

Economics are concerned with the provision of mankind's material needs, which are goods and services, and the goal of economic progress is perfection in that provision. I, therefore, submit as a suitable definition with which to begin the study you recommend, the following:—"Economic progress consists of increased capacity to produce and deliver goods and services as required, with the same or less expenditure of energy."

London, W.C.1, September 29th. W. T. Symons.

THE GROWTH OF SCIENTIFIC JARGON.

Sir,—The progress of science and engineering, as a whole, depends on the interchange of ideas. As you point out, this interchange between technicians necessitates the use of "specially selected or restricted meanings" to words. What I urged at Leicester was that it is time to call a halt in the game of applying special new or restricted meanings to words. For example, as a student of geology, I still do not know what a geological bifed is. Of course, I have naturally met the term in other branches of science.

The suggested use of only 850 words in basic is for the communication of ordinary ideas; an additional hundred words are required for general science. There is no question of trying to express science papers in 950 words—the word list is not intended to include thousands of proper names which are necessary. On the other hand, supporters of basic English are alarmed at the very "magnitude and free growth of the language" which you praise. We do urge most strongly that it "is" time to introduce a definitely restrictive agreement on the enormous growth of different terms and different names for the same things in different languages. A start on these lines has been made by organic chemists. In Germany a great deal of attention has been applied to the standardisation of electrical engineering terms, and in the U.S.A. a big movement is now on foot to review scientific and technological terms used in a variety of industries.

I can see no logical reason for, and no scientific gain whatever from, a multiplication of different names in engineering and science for the same things in different languages. One might as well suggest that 480 different names should be invented for the kilogramme so that every nation and native tribe could indulge in freedom to introduce new names and assist in the unrestricted development of its language. B. W. Holman.

London, September 28th.

RAILWAY SPEED.

Sir,—Your paragraph in The Engineer this week on the "remarkable speed records" established by the L.M.S. Company between Euston and Coventry on September 19th, omits to mention the fact that the timing of trains between London and Birmingham has not been improved by so much as a single minute for over thirty-one years. Indeed, the present timing, though nominally the same, is actually rather slower than it was when my old friend, the late Charles Rous Marten, wrote an account of a Birmingham to London journey in The Engineer for August 8th, 1902.

Between other great business centres, such as Paris-Bordeaux, Berlin-Hamburg, or New York-Buffalo, railway service becomes steadily better and better; here, in Britain, what was good enough for our fathers is still considered good enough for us.

Anyone who travels in foreign countries to-day must be struck by the general rise in the standard of railway performance; the French would take an hour off the time allowed for the non-stop "Flying Scotsman" between London and Edinburgh, and our possession of one "Cheltenham Flyer"—a light train in a service of minor importance which runs at high speed for part of its journey—is poor compensation for the existence of many services, which, according to modern ideas, are quite second-rate. W. B. Thompson.

London, S.W.1, October 2nd.

The Victoria, Southern Railway, Buffer Stop Collision.

At about 8.47 on the morning of April 25th last, the 7.40 a.m. electrically operated train from Brighton collided with the spring buffer stops at the end of No. 14 platform, Victoria. There were no serious personal injuries, whilst only trifling damage was done to the rolling stock, and the buffer stops were not displaced. The rails near the buffer stops were slightly greasy.

The train consisted of twelve bogie vehicles in two six-coach sets. Its length was about 226 yards and its unladen weight about 532 tons. It was fitted with the Westinghouse brake, working blocks on all wheels. Screw couplings and side buffers, the latter of a heavy shock-absorbing type, were in use throughout the train. The draw and buffing gear was undamaged by the collision.

An unusual feature of the accident was that although the train appears to have entered the station at normal speed, and the impact between the leading motor coach and the buffer stops was not severe, there was a violent rebound of the three coaches at the rear of the train, in which many of the passengers who were injured were travelling; the brakes of these three coaches were found to be off immediately after the accident.

In order to ascertain the time needed for a brake application to become effective at the rear of a twelve-coach train, the company arranged to make some tests at the Selhurst depôt.

In the fourth of these tests attempts were made to reproduce the conditions of the accident; that is to say, to apply the brakes on the first nine vehicles and not on the last three, by manipulating the brake valve in the manner described by the motorman. After applications with 10 lb. to 12 lb. reduction in train pipe pressure lasting for about 1½ minutes, corresponding to the time taken to run from Grosvenor Bridge to the entrance to the station, the brake valve was placed in the release position for ten to fifteen seconds. During the ensuing thirty to forty seconds several slight applications were made, without moving the handle back to the lap position, with resultant total reductions of from 25 lb. to 30 lb. in the train pipe pressure. In all cases the brakes were found to be applied throughout the train at the conclusion of the tests.

A further test was then made to reproduce as far as possible the manner of handling the brake valve described by the motorman at the company's investigation of the accident. The original application and release were made as in the fourth series of tests, and the brake was then applied again, with 10 lb. reduction of train pipe pressure, for twenty seconds, representing the run from the entrance to the station up to Victoria North signal-box. The brake valve handle was then moved to release for twenty seconds, after which two short applications, each of about a second, were made. It was found after this that the brake was applied on the first six vehicles of the train, but not on the last six; another short application applied the brakes on the seventh and eighth coaches, and a further one, rather more lengthy, applied it on the remaining four vehicles of the train. It was also found that in releasing the brake after this test the triple valves on the twelfth vehicle reversed six seconds after the brake valve was placed in the release position; the blocks on this coach did not leave the wheels until a further nine seconds had elapsed, or fifteen seconds in all after the brake valve was operated.

In the conclusion to his report, Colonel Woodhouse says that it is clear from the evidence that the speed at which the train entered the station and approached the buffer stops was not excessive, though, in this connection, the motorman's estimate that his speed was only 5 miles an hour at the platform ramp (420 yards from the buffer stops) is obviously faulty; the platform is nearly a quarter of a mile long, and at such a speed a train would take three minutes to reach its inner end.

He is of opinion that the accident was due to errors of judgment on the part of the motorman, not only in delaying the final applications until the train was too close to the buffer stops, but also in the manner in which these applications were made, and that responsibility for it rests with him alone.

The Report concludes with the following summary and recommendations:—(1) The collision with the buffer stops was due to errors of judgment in handling the brake on the part of motorman Coughtrey, resulting in it being temporarily inoperative on the three rear vehicles of the train immediately before the accident. This gave rise to a violent rebound of the three vehicles in question.

(2) The response of the ordinary Westinghouse brake equipment to the motorman's actions, while quicker than that of the vacuum brake, is far from being instantaneous. Consequently, more dexterous operation of the brake is needed on long trains than on short ones; liberties which can be taken with it on the latter, without untoward results, may easily give rise to unevenness of braking on the former.

(3) No reasonable objection can be raised to the company's practice of transferring motormen from heavy expresses to short suburban trains and *vice versa* during the course of a day's work. But as this may lead to injudicious handling of the brake on the longer trains, through momentary forgetfulness on the motorman's part, the need for deliberation in the manipulation of the brake valve on all occasions, on short as well as on long trains, should be impressed upon motormen.

(4) Two improved forms of Westinghouse brake equipment have been developed, namely, the high-speed air brake and the electro-pneumatic brake. Both of these give to the motorman fuller control of brake action than he has with the ordinary Westinghouse equipment; in addition, the second possesses features rendering it specially suitable for use on multiple unit electric stock, of which a very important one is that the response of the brake to the motorman's actions is not affected by the length of the train. This simplifies the task of a motorman who has to change round frequently between trains differing in composition and length.

(5) While it is true that the operating conditions of an express service, with infrequent stops, differ from those on the London Underground, on which the electro-pneumatic brake is understood to be giving excellent results, it appears, nevertheless, that in any type of service the added measure of control of the brakes afforded by these improved patterns of equipment must be valuable. I suggest, therefore, that the company be asked to consider the experimental use of, at any rate, one of these two forms of improved brake equipment—preferably the electro-pneumatic—in order that it may be ascertained if the advantages described are realised in practice, and justify the expense involved, having regard to the various operating conditions of their electrified services.

Experiment of this nature on surface lines would appear to be distinctly advantageous at the present time, in view of the possible extension of electrification.

The Institute of Marine Engineers.—Since the Royal Charter was granted to the Institute in March last, an important alteration has been made in the regulations governing the admission of students. A detailed syllabus of the student examination has been issued, with particulars of exemptions open to candidates possessing certain educational qualifications. The next examination will be held in May, 1934, at various centres, according to the candidates' places of residence. Full particulars may be obtained on application to the secretary, the Institute of Marine Engineers, The Minories, London, E.C.3.

Railway and Road Matters.

The oil-electric "railbus," designed and built by Armstrong, Whitworth and Co., Ltd., is now in regular service between Newcastle and North Wylawn.

The report by Lieut.-Colonel Woodhouse on the buffer stop collision of April 25th at Victoria, Southern Railway, was issued on September 30th and is reviewed on another page.

All four grouped companies had not only, as was to be expected, increases in passenger traffic for the thirty-eighth week, but in goods traffic also. The several increases in the latter were:—Great Western, £20,000; L.M.S., £22,000; L.N.E., £38,000; and Southern, £3000. The Southern has now an advance of £51,000 in its total receipts for this year as compared with the corresponding period of 1932.

A recent letter in *The Times* on the subject of the electrification of railways, points out that were all the lines running into New-street Station, Birmingham, worked by electricity, that station could be covered in and thus provide space which could be used for the great benefit of the city. We draw attention to this suggestion because of the large sums of money that now come in that way to the Grand Central Station in New York.

On Saturday evening last, September 30th, as a passenger train from Glasgow to Ardrossan was running between Beith and Glengarnock, one of the carriages was struck by an obstruction from a passing goods train and a passenger killed. It is said that it was an iron bar, which was part of the structure of one of the wagons, that had become detached. It might, we suggest, have been a load that had shifted in transit; in either event the occurrence was unusual.

When Mr. W. K. Wallace came from the position of engineer and locomotive engineer for the L.M.S. Northern Counties Committee to Euston in 1930 to be chief storekeeper, and, later, chief civil engineer, he was succeeded at Belfast by Mr. H. P. Stewart, who has now retired and his duties have been taken over by two of his assistants; Mr. R. L. McIlmoyle, assistant engineer, becomes the civil engineer, and Mr. M. Patrick, the running superintendent, is made the locomotive engineer.

But for the unfortunate death, on July 6th, of Mr. W. A. Traill, its founder, the Giant's Causeway Railway would have celebrated its jubilee last week. Actually the line was inspected by General Hutchinson, on behalf of the Board of Trade, on January 12th, 1883, and opened on the 18th idem. As the proposed electrical equipment was not ready the line was worked by a steam tramway engine. On September 28th following the work was complete and was then formally opened by Earl Spencer, the Lord Lieutenant.

In any consideration of the Ministry of Transport railway statistics for June it must be remembered that it includes Whitsuntide, whilst that holiday period was in May last year. The number of passenger journeys was 6·7 per cent. more in June, 1933, than in 1932, and the receipts were up by 12·6 per cent. For the four weeks ended July 15th the tonnage of freight increased by 4·6 per cent. over the corresponding period of 1932, and the receipts by 0·6 per cent. There was a rise of 1·2 per cent. in the freight train miles and the average train load increased from 113 tons to 116¾ tons and the net ton-miles per engine hour from 427½ to 446.

Spray-cleaning for locomotives is now in force at a number of depôts in the southern area of the London and North-Eastern Railway. According to that company's magazine for September, the plant consists of an electrically driven automatic-controlled three-throw hydraulic pump, which forces a mixture of hot water and a degreasing compound, such as soda ash, through suitably arranged pipes to the near vicinity of the engines to be cleaned at a pressure of 375 lb. per square inch. Flexible pipes are coupled to the fixed supply line, and the cleaning mixture is ejected from a specially designed gun in a solid jet of fluid which may be directed with considerable force to any part of an engine which has to be cleaned.

The announcement that the London, Midland and Scottish Railway is about to strengthen the bridges between Mangotsfield and Bath on the former Midland Railway, raises the question why that is being done. The line, which was opened on August 4th, 1869, carries no heavy traffic except the Bournemouth expresses to and from the North. The explanation is probably to be found in the fact that the L.M.S. is responsible for the locomotive power for the jointly owned Somerset and Dorset Railway—the Southern Railway takes the civil engineering—and to deal with the steep gradients on that line has some heavy locomotives stationed at Bath. The strengthening of the bridges in question will permit a wider use of those big engines.

There was a sequel, at the County Police Court, Penrith, on Wednesday, September 27th, to the fatal collision of July 10th at Little Salkeld, which explains why the coroner's inquest at Carlisle was again adjourned on September 12th. The sequel was that the signalman was charged with manslaughter and was subsequently committed for trial at Cumberland Assizes. The signal-box at Little Salkeld is opened only when any shunting movements have to be made, and about 1 p.m. on the day in question a down freight train arrived which had a wagon to place in the siding on the up side. Before the points could be opened for the shunt to be made the up distant and the up home, which stood at "clear" whilst the box was closed, had to be put to their normal position, but before that was done the signalman should turn the switching-out instrument, which would tell him if any trains were in the Lazonby-Langwathby section, in which Little Salkeld is an intermediate box. It is charged against the signalman that he did not turn the switch, but, instead, put the signals "on" and opened the points. An express from Carlisle to St. Pancras was, however, in the section and it had passed the distant, 750 yards away, before it was changed, and the express consequently caught the engine that was shunting and so injured the driver that he died in Cumberland Infirmary the following day.

Notes and Memoranda.

The number of telephone stations connected to the Post Office system at July 31st was 2,159,140, an increase of 3551 over the total at the end of June.

The House Committee of the Victoria Parliament has been asked to consider the improvement of the acoustic properties of the Legislative Assembly Chamber by the installation of a system of amplifiers operating loudspeakers.

The manufacture of ethylene dibromide for use as a constituent of anti-knock motor fuels probably represents the most important industrial outlet for bromine to-day. The content of bromine in sea water, about 0·007 per cent., seems, says the *Chemical Trade Journal*, uneconomically small, but the magnitude of the total quantities available will be appreciated by realising that 1 cubic mile of sea water contains 600 million pounds of bromine.

The study of wood shrinkage has been continued by the Forest Products Research Board, and various further aspects of the subject investigated. The contention that old timber is more stable than newly seasoned timber is being studied. Sample pieces of old timber have been obtained from old buildings and matched samples of new timber have been prepared. The matched pairs are being subjected to changing atmospheric conditions, and any dimensional changes noted. At the moment the indication appears to be that there are only slight, if any, differences in the amount of movement of old and new wood.

A very unusual form of boiler explosion is described as follows in the latest report on factory accidents issued by the Home Office. A boiler used for supplying steam to a gas generator had been emptied, for renewal of the fusible plug, and the stop valve on the steam pipe to the generator closed. After removal of the manhole cover, a worker approached the manhole with a lighted candle. An explosion occurred and the worker was burnt. It was subsequently found that the stop valve was faulty, and the removal of the water presumably caused some residual gas from the generator to be drawn into the boiler shell. This accident shows that where leakage of gas is liable to occur it is not safe to rely solely on a closed valve; in all such cases a blank flange should be inserted in the pipe line to prevent the danger of an air-gas mixture being formed. In addition, naked lights should obviously not be used in places where inflammable gas may be present.

It appears from a note in the *Electrician* that unless action is taken at once the influx of Japanese lamps will be supplemented by a serious invasion of the British market by Russian bulbs. The Soviet Government is said to be preparing to ship millions of electric lamps to this country at a wholesale price of 2½d. each, to be sold retail at 4½d. to 6d. An *ad valorem* duty is quite useless to deal with a menace of this kind. The Import Duties Advisory Committee was asked by the British lamp manufacturers a year ago to substitute a specific duty for the 10 per cent. *ad valorem* duty now in force, but nothing has yet been done, and a British industry which gives employment to large numbers of workers and represents an investment of several millions sterling is now faced with the prospect of competition, not only from low wage countries, but, our contemporary concludes, from a State which trades at prices that have no relation to the actual cost of production of goods.

An oil engine of the sleeve valve type failed after a few weeks' service and was rather badly wrecked. Subsequent investigation suggested that the cause of the trouble was the "gumming up" of the valve sleeve. Commenting on the incident, *Vulcan* suggests that the formation of gum on the sleeve was apparently caused by the engine having been consistently run with the cooling water which supplied the jackets at too low a temperature, the water in question being on a run-through system direct from the pumping station mains. Arrangements have therefore been made for heating the circulating water in future, in order to avoid the possibility of a recurrence of breakdown and damage from this cause. It might be added that it is not, as some oil engine owners are inclined to think, good policy to work an internal combustion engine with the jacket water at too low a temperature, as not only has it been shown that this results in low fuel efficiency, but, at the same time, it increases the wear on the cylinder liners.

An accident, resulting in the death of one workman and injury to several others, occurred during the extrusion of small rods of an alloy containing 55 per cent. zinc and 45 per cent. lead. Following the receipt of a (foreign) trial order for rods of this composition, an ingot was prepared by pouring the requisite mixture into an open cast iron mould standing on end. The ingot was allowed to cool thoroughly and a discard of about 25 per cent. was removed by cold sawing. The billet, after being reheated, was placed in an extruding machine with the sawn face to the die and extrusion commenced. About 75ft. of metal were successfully extruded through each of the holes in the die plate, when fragments of metal were suddenly projected forwards at a high velocity. Two men guiding the extruded rods down the delivery trough both received a large number of wounds and two other workers were less seriously injured. Subsequent analysis showed that both the discard and the extruded rod consisted of zinc containing about 2 per cent. of lead and that the projected fragments and the part of the billet which remained in the machine (with the exception of a thin layer of zinc near the die plate) consisted of lead containing 1 to 2 per cent. of zinc, which indicates that the mixture of metals, on cooling in the mould, separated into lead and zinc. The billet had been placed with the zinc end towards the dies and zinc rod was first extruded quite evenly; when the thickness of the zinc layer had been reduced to about ¼in. the lead was forced through it with explosive violence and projected at high velocity from the machine in the form of irregular nodules. This accident, states the Home Office report on factory accidents, illustrates the fact, well known to metallurgists, that lead and zinc will not alloy at ordinary temperatures except to the extent of about 2 per cent. of either metal with 98 per cent. of the other.

Miscellanea.

Two electric power plants, each with an output of 130 kilowatts, are being erected near Balaklava.

The Portland cement plant at Saichuen, in the western suburbs of Canton, is being extended to double its present capacity of 1300 barrels a day.

Owing to the death of its President, Mr. T. W. Ellis, Mr. C. Strachey Hawdon, A.M. Inst. C.E., M.I. Mech. E., A.C.G.I., has been elected to fill the presidential chair of the Institution of Engineering Inspection for the remainder of the current session.

It is expected that the output of one of the blast-furnaces of Dorman, Long and Co., at the South Banks Works, which has been remodelled and its hearth diameter increased from 12ft. to 16ft., will now be twice the original amount of 200 tons a day.

An important phase in the development of Sierra Leone, one of the oldest British West African possessions, is marked with the arrival at Glasgow of a shipment of 8000 tons of iron ore from the Colony. It is now believed that Sierra Leone will be able to supply Britain with a large proportion of its foreign iron ore requirements.

Two new electric winding machines are to be installed by the Union Corporation, Ltd., of Johannesburg. They are to be of the Ward-Leonard type, with mechanical parts by Fullerton, Hodgart and Barclay. The maximum load is to be 6000 horse-power, and they will wind from a depth of 4400ft. The contract price is over £50,000.

The Dominion Bureau of Statistics at Ottawa reports that selenium production in Canada during the first six months of 1933 amounted to 8600 lb., valued at 17,200 dollars. This metal is obtained as a by-product in copper refining, and was produced for the first time in Canada early in 1931 at the plant of the Ontario Refining Company, Ltd., Copper Cliff, Ontario.

At Marioupol, close to the shores of the Sea of Azov, construction work on the great Azovstal steel plant is proceeding at a rapid pace. The first Azovstal blast-furnace has just been started up. It is built on lines identical with those of the furnaces at Magnitogorsk, but it is slightly smaller, having a capacity of only 930 cubic metres. The works are being connected with the sea of Azov by means of a ship canal.

Speaking at the annual dinner of the British Commercial Gas Association, Dr. Burgin, Parliamentary Secretary to the Board of Trade, said that the most important result of legislation to follow the Departmental Committee's report would be to enable the industry to grant to consumers who would take bulk supplies at off-load periods, better-priced terms than could be given to consumers who were unable to offer such advantages to the industry.

The newly built Ryon hydro-electric station in Russia has been set to work. The station, which is on the river Ryon near Kutais, has a capacity of 48,000 kilowatts, and is the largest hydro station in Transcaucasus. It will supply energy to the electrified section Zestafani-Stalinici of the Suram Railway, the manganese plant and various factories in Kutais, as well as to collective farms in Georgia. The station is equipped entirely with Soviet-made machinery.

The 3,000,000-dollar bridge spanning the St. Lawrence River between Caughnawaga and Ville La Salle, which is being erected by the Lake St. Louis Bridge Corporation, will, says *Canada*, in all probability, be completed approximately a year ahead of time. Plans called for completion of the structure by May 1st, 1935, but it is now probable that the work will be finished by July 1st next, according to the Minister, who added, "At the present time the contractors are both ahead of time and under original estimates."

Two new three-phase Heroult furnaces have been completed at the wire works buildings of the Union Steel Corporation at Vereeniging. These furnaces have, says the *South African Mining and Engineering Journal*, been installed primarily for the production of hollow drill steel, but they will also produce tool and alloy steels of the types required by local industry. Between them these furnaces will have an annual capacity of close on 5000 tons of liquid steel, giving a marketable yield in the region of 3000 tons.

Plans are already well advanced for the erection of a new synthetic rubber factory, for which a site has been laid out a few kilometres from Erivan, in Russia. Work has been started on the building of accommodation for the labour force and technical staff. The new factory will be conveniently located with respect to carbide and chromide plants, the sources of raw material required in the manufacture of synthetic rubber, and electrical energy will be transmitted from the new Kanakir electric power station, over a distance of some 10 kiloms.

An interesting ceremony was performed on October 2nd, at the Forth Paper Mill of J. A. Weir, Ltd., Kilbagie, when Mrs. S. S. Lamert, wife of the chairman of the company, started up the new Yarrow boiler plant, and Mr. Lamert opened the steam valve to transfer the works load to the new plant. It is anticipated that the consumption of fuel will be reduced by approximately 35 per cent. from that required for the old plant which is being replaced, and that the lower grade of fuel, so plentiful at Scottish collieries, will be utilised, and freedom from smoke and grit trouble will be secured.

The outstanding feature of the Janjula hydro-electric power station which utilises the water of one of the principal tributaries of the upper Guadalquivir, in Southern Spain, is, says the *Electrical Review*, that it is built entirely in the dam of the power development. This dam is a solid gravity type dam of concrete, 306ft. high and having a length of 720ft. at the crest. The machine-room as well as the rooms containing the H.P. switchgear, are in the form of vaults at the base of the dam, the outer walls being up to 10ft. thick. The power station is equipped with three vertical generating sets. Two of these have a capacity of 7500 kVA, while the third develops 3750 kVA at 10,000 volts, 50 cycles, three-phase.

PATENTS & GOVERNMENT DEPARTMENTS.

UNDER the Order in Council of July, 1915, amended in 1928, by which it was established, the Department of Scientific and Industrial Research is permitted to take out patents for inventions and discoveries made by its servants and research workers. In 1922, an Inter-Departmental Committee presided over by Mr. Kenneth Lee considered the question and reported upon the methods to be followed in connection with patents made by "workers aided or maintained from public funds." That Committee did not report on the propriety or otherwise of patents being held by public servants or Departments. But even in the earliest days of the D.S.I.R. it was foreseen by astute observers that this privilege would, sooner or later, lead to trouble with private inventors. Recent events, which need not be particularised, have brought that matter to a head. The leaders of the present movement are chemists and chemical engineers, but the question is of moment to all who are engaged in any of the activities in which the D.S.I.R. interests itself. It is an extremely difficult one, in which the *pros* and *cons* are so nicely balanced that a decision one way or the other—in favour of or in opposition to the holding of patents by a State organisation—cannot readily be reached. That injustice, or apparent injustice, may sometimes be done to the individual is not in doubt, but apart from the fact that the public weal must come before individual benefit, cases may arise, and have arisen, in which the patents of the D.S.I.R. have restrained foreign competition and by so doing have aided the British manufacturer.

In view of the certainty that before long the matter may receive public attention, we think it may be of assistance to our readers if, without swinging to right or left, we devote a few words to a presentation of the main aspects of the problem. In the first place, it is desirable to recall the purposes for which the Department of Scientific and Industrial Research was established. According to the terms of the Order in Council of 1915 it is "to direct, subject to such conditions as the Treasury may from time to time prescribe, the application of any sums of money provided by Parliament for the organisation and development of Scientific and Industrial Research." At first its energies were directed principally to encouraging, and to helping financially, Research Associations established by industries. But it soon found a necessity to carry on researches of its own in the national interest, and at the present time, in addition to the National Physical Laboratory, numerous researches are directed by it, amongst which may be mentioned Building Research, Chemical Research, Food Investigation, Forest Products Research, Fuel Research, Radio Research, and Water Pollution Research, and it has several research stations and laboratories. From its very nature much of the work carried out in these laboratories has industrial value and importance, and many of the results are patentable. There were three courses open to the Department with regard to the latter. It could, like the national research organisations of other countries, protect them by patents taken out in the ordinary manner; it could throw them open to the world; or it could reveal them to certain selected individuals or firms for the purpose of industrial development. At first sight it would appear that the right course for a public body, supported by public funds, is to publish openly its discoveries and inventions. We may recall a story which shows what may happen when that is done. Many years ago, Laval, the inventor of the centrifugal separator, designed a hand-worked cream separator for use in the household. In the interest, he believed, of the world at large he threw the design open to all and sundry. Anyone who desired could make it. But the result was the very opposite of that intended. Instead of a plentiful supply of these little separators at competitive prices, none were made because no one could secure a monopoly for their manufacture. This familiar story shows just what might occur if the D.S.I.R. made it the standard practice to publish its inventions to the world. To guard against that mishap it decided to keep control of its inventions by patenting them and by licensing the use of them under royalties in the usual way. A further advantage is gained by this course in that foreign competition can be checked or controlled. Against this argument in support of departmental patents we must set down a possible injustice. It may happen that the Department is working on a problem which has also attracted the attention of private individuals or firms, and that the same solution is reached by the Department, with its excellent resources and public moneys, before the individual or firm. If then the Department covers the invention by a patent the private worker is robbed of the fruits of his labour. Manifestly the condition set up is undesirable. For, on the one hand, the private individual will be discouraged from making inventions, foreseeing that it is more economical to leave that work to the Department; or, on the other, he may be tempted to take out a great number of "keep off the grass" patents in order to circumvent the Department. There are already too many patents of this kind, and anything which tends to encourage their multiplication is to be deprecated. But in this connection it is very important to remember that whilst the D.S.I.R. has no right to ask private manufacturers what they are doing, the research programme of the Department is open to all manufacturers. Furthermore, if any firm engaged in a research has reason to believe that the D.S.I.R. is interested in the same research, it will be shown what the Department is doing, and if the Department is satisfied that the firm is covering the ground it may either co-operate with it or delete the item from its own programme. The third alternative open to the Department is to place its inventions in the hands of a selected firm or group of firms with permission to protect and use them, either for or without a "financial consideration." Whilst the arguments which may be advanced against that course leap to the eye, it has merits which cannot be overlooked, and which in certain cases would seem to outweigh the objections. In any case it cannot be hastily dismissed on the ground that it may be a form of favouritism. In the cause of national economy it may be the right and proper thing for a national body to go direct to one or two firms which, by their association, are known to have the means and the ability to make the best of an invention.

From this brief survey of the position it will be seen how difficult the problem is. One solution is to close all the Department's research laboratories, and we believe there are some who favour that course. But if the laboratories directed by the Department were closed down, what would be done with the laboratories, like that, for example, of the Cast Iron Research Association, which also may take out patents and are in part supported by the Department; and what with the private research workers in colleges who may secure patents on inventions resulting from labours for which the Department has, in part, paid? Logically, the rule would have to be enforced that no laboratory and no individual receiving payment of any kind from the D.S.I.R. may cover any resulting invention by a patent. Such a rule is unthinkable, for it would not only hit the State laboratories and private workers, but would weaken the activities of the Research Associations, for the encouragement of which the Department was established. The only *complete* solution is the demolition of the whole structure of the D.S.I.R., which even its severest critics would scarcely desire. We trust that some *via media* between the best interests of the nation and of the individual citizen may result from deliberations which are now taking place.

Autumn Meetings.

Two important institutions, the Iron and Steel Institute and the Institute of Metals, have just held their autumn meetings at Sheffield and Birmingham respectively. Both may well be described as successful and even brilliant. There can be no doubt that the improved industrial atmosphere at Sheffield contributed much to the success of the Iron and Steel meeting, both in regard to the lavish hospitality which was extended to the visitors and to the spirits and energy of those taking part. At Birmingham, also, where the Institute of Metals celebrated its twenty-fifth anniversary, there were signs of renewed energy and activity in many directions.

While, therefore, we can congratulate both Institutions upon their meetings, we feel that there is room for some comment. There is, on these occasions, always some divergence of opinion as to the nature of the papers which should be read and discussed. There are those, and, to a large extent, we sympathise with them, who consider that papers of direct industrial interest, if possible specifically relating to the industries of the district where the meeting is held, should constitute a prominent feature of the programme. So far as the Iron and Steel Institute is concerned, this type of paper always forms a large proportion of its proceedings, and the meeting at Sheffield was no exception. Many of these papers are of very great interests, and are prepared not only with skill and ability, but with a degree of frankness on the part of the authors and the firms they represent which is most commendable. On the other hand, it is a criticism which could have been justly levelled at the Iron and Steel Institute on previous occasions that the more scientific aspect of iron and steel metallurgy does not receive adequate attention at the meetings themselves. At Sheffield we are glad to say that this want of balance was not so apparent. Some scientific papers, among which we are glad to include certain sections of the Fifth Report of the Committee on the Heterogeneity of Steel Ingots, received very satisfactory discussion of a character which should be helpful to the further progress of the work. At the Institute of Metals, on the other hand, there was a very distinct lack of balance. Mr. Barclay's Autumn Lecture, which we have reproduced in abstract, did, of course, deal in a most interesting manner with purely industrial matters, and one or two of the other papers related to alloys which appear to have a promising commercial future. All the remaining papers, however, both those read and discussed, and those merely formally presented, were definitely of the "research" type. While we recognise the value of papers of this kind and the good work which the Institute of Metals has done, and is doing, in affording facilities for their publication and discussion, we still feel that a larger number of papers of a more directly industrial type should be contributed either by manufacturers of non-ferrous metals, or by the engineer-users of these materials. They would certainly add very much to the value not only of the meetings themselves, but of the published "Proceedings" of the Institute. We believe that the Council of the Institute of Metals is most anxious to secure papers of this kind, and, therefore, suggest that it is the duty of engineers and manufacturers to provide the necessary material. We cannot believe that subject matter for such papers does not exist in ample measure throughout the non-ferrous industries, nor that the men engaged in these industries are incapable of putting their facts and experiences into a form which would be acceptable to their colleagues. Possibly, however, there may still be a certain measure of the old attitude of secretiveness in these industries, and this may perhaps be holding back information and views in reality suitable for publication.

We cannot enter here into the large subject of the desirability for publication and the free interchange of knowledge and information, not only of a scientific, but of a technical and practical nature. We would only remind those who still hesitate on this point that experience has shown that firms and individuals who are most ready to communicate the results of their own experience have always been found to profit by the interchange which such publication brings about. While we realise that there are occasions when temporary non-publication is desirable, or even necessary, we feel satisfied that there is a great deal which could and should be described and discussed, and that, if it were, general benefit to all concerned would result. The Institute of Metals, in particular, provides a field where both the manufacturers and users of metals can profitably exchange their views. Possibly some of them are a little shy of an atmosphere which is perhaps somewhat scientific, but we suggest that such shyness is unnecessary and unwise. We feel sure that no one would be better pleased to see industrial papers presented and discussed than the scientific metallurgists themselves. The fructification of their work must largely lie in the development of industry, and new fields for application will often be opened up by a free discussion of industrial rather than purely scientific problems.

Waste in Manufacture.*

By C. R. F. ENGELBACH.

THE structure of all prime manufacturing costs is built up solely on the price of labour and charges—the labour expended in winning the raw materials from land, air and sea, and transporting them to different stations, whereby, again by labour, they are converted into finished articles.

It is calculated that in any finished mechanical appliance about 84 per cent. of the cost is productive labour, the remainder being represented by fixed charges and whatever profits may accrue during the various processes through which it passes from raw materials to the finished article.

Nature provides all basic materials free of cost, and as she is lavish in her gifts, it is perhaps for this reason we are so prodigal in our use of them. These free gifts are supplied for the use of mankind in vast quantities, but, owing to our imperfect knowledge, we have to pay in terms of labour very heavily for adapting them to our purpose.

During the last twenty years, however, the labour employed in the manufacturing of motor cars from semi-raw materials has been steadily decreasing. We are only a finishing industry, and therefore our cost structure includes the purchase of semi-finished material to which we add our own productive labour; but the ratio of this labour cost to the "material cost" has in the last few years, in consequence of improved methods and organisation, decreased enormously, and the material cost now forms a very much larger proportion of the total than formerly.

Our efforts have been concentrated on reducing operation times by minutes and seconds. New plant, new machines, new devices to save time in machining or handling; new methods, new processes and new ideas on organisation have flowed unchecked from the brain of the engineer.

Thousands of pounds have been spent on installing new plant and labour-saving devices, but I venture to say that insufficient attention has been paid to the elimination or reduction of the waste—the appalling waste—that occurs in the materials we use in the production of a car.

In brief, in twelve months, the Austin Motor Company purchased 68,777 tons of materials, out of which 18,200 tons were *entirely finished* and required no labour before assembling into a car. In order to finish these goods and to deliver them in completed cars we used 14,112 tons of commodities which might be termed "Consumable Stores," and the fuel used for power and light supplied by ourselves and from Corporation sources, heating and various processes, came to no less than 63,157 tons. Adding these together, we arrive at the following:—

Productive materials	68,777
Consumable stores	14,112
Coal and fuel	63,157
Total	146,046 tons

The total weight of the goods sold in motor cars and spare parts was 33,762 tons, so that by a process of simple arithmetic it will be seen that the loss in tonnage was 112,284. In other words, we delivered to our customers 26 per cent. of the total materials received and 74 per cent. was consumed or wasted in various processes.

The Foundry.—Even before the foundry starts its legitimate work an enormous tonnage of materials has been used to provide the pig iron from which our castings are made. In order to produce 170 tons of finished castings, 1000 tons of iron ore, 600 tons of coal, and 200 tons of limestone, a total of 1800 tons, have been used to produce this relatively small tonnage of castings, and although we who run foundries can only control the process from the receipt of pig iron as a semi-raw product, even then we use 276 tons of this commodity for our 170 tons of castings, and are responsible, therefore, for a loss of over 60 per cent., irrespective of the coke and other ingredients we use in their manufacture.

I feel bold enough to state that the engineer has not yet come into his own in the foundry, and more often than not there is an air of mystery and superstitition in the method of making castings, reminiscent of the days when the leg of a frog or a bat's wing were added to the mix to ensure a perfect result.

The Stamp Shop.—Stampings produced by forging hammers, drop stamps, steam hammers, hydraulic presses, or upsetting machines, form the basis of a more modern process of manufacture than the foundry.

The loss of accumulated labour during the process of converting iron ore into the finished stamping is even greater than in the production of castings, as the metal from the steel furnace has to be cast in ingots, of which 20 to 25 per cent. is cut off as waste, before being rolled into bars and billets for stamping purposes.

Our 1000 tons of iron ore take 610 tons of coal and 200 tons of limestone before it can produce sufficient material to make 124 tons of stampings. As stampers we can only govern the loss from the receipt of the bars or billets until the completed forging or stamping is actually in being. The actual loss between the weight of the finished stamping and the steel bar or billet purchased naturally varies with the type of stamping that has to be produced, but, if serious, and I may say scientific attention is given to the problem of losing as little material as possible in the flash and tag ends, much can be done to reduce the wastage.

A modification of stamping technique is required so that a minimum of surplus metal must be left on the stamping instead of the usual allowance required to enable the machinist to get under the skin of the metal, and further, it may be necessary to modify the stamped shape in order to accommodate the part in the squeezing dies.

The Press Shop.—The press shop is another very important department in any automobile factory, and especially in those firms manufacturing their own bodywork. Here, again, the waste of expensive materials seems appalling when viewed over a yearly period, and deserves much more attention than it usually receives.

In the Austin works we use 16,000 tons of sheet metal annually, the price varying in accordance with gauge and specification from £13 to £22 per ton. But as the majority of this material is used for the shell structure of the body, which requires the most expensive grade of sheet, the average works out at about £20 per ton, and from this it will be seen that our yearly bill is approximately £320,000.

Of this we scrap and throw away 35 per cent., *i.e.*, to the value of £112,000, for which the scrap merchant only gives us £7000. In other words, we discard £105,000 worth of this material and receive nothing in exchange!

A 35 per cent. waste is generally considered a satisfactory percentage in a press shop, but this figure must be somewhat humiliating to those who pride themselves on their efficiency.

The actual percentage of scrap, due to faulty work, is comparatively small, say, 3 to 5 per cent., the remainder being the waste due to the process itself and in having to blank awkward sized pieces from square or oblong sheets.

By a more scientific plotting out of pressings and intelligent use of off-cuts a great deal of material can be saved, and since this paper was commenced a reduction in this waste percentage has actually been made in our own works.

The greatest advance, however, can be made in a closer *liaison* between the press-tool maker and the designing office. Too great stress cannot be laid upon this, as success or failure of economical press work manufacture can be attributable to the close co-operation or otherwise of these two important departments.

The Paint Shop.—I only wish to introduce a short paragraph on the waste that occurs in the motor car paint shop.

After great difficulties I succeeded in getting the correct weight of a 7 H.P. saloon body before and after painting. The actual amount of painting materials and stores issued for each body was 22 lb., and it was found that the materials which finally adhered to the finished body weighed only 2 lb.! The greater proportion of this loss, of course, is accounted for by the fact that the materials used in painting are to a very great extent volatile in their nature, but the extraordinary disparity has given us, as the French say, "furiously to think," and here again a noticeable improvement has been made since these facts were established.

RESEARCH.

Many of the problems which I have considered could be solved by intensive study and the preparation of careful statistics in the individual works, the chief point being the discovery of where the greatest wastage is occurring. Some of the problems, however, are so complicated and involve such a long study that they cannot be tackled by any one firm, and it is here that the great value to the industry of the Research and Standardisation Committee will be found. In the recent research on cylinder wear, for instance, it has taken about eighteen months of intensive study and gradual elimination of the many variables to discover the most probable cause of the trouble, and it may even now be some time yet before a cure can be definitely claimed. There are few firms who could afford to wait such a long time for any showing, and their Research Department would be constantly being pushed by the directorate for results, whereas the Research Laboratory at Chiswick can pursue their investigations free of any such commercial urge. The Committee certainly deserves the fullest support of all manufacturers.

I may remind our members that politics *never* assisted in lowering costs of production. Politics always tend in the opposite direction, and we have to fight hard and continuously for our industrial existence.

Our salvation lies within ourselves and ourselves alone. Rises in world commodity prices may be politically sound and furnish good propaganda for a return to prosperity—minimum wages and shorter hours of work may be forced upon us, and perhaps, *quien sabe*, such alterations in our economic and industrial outlook may be eminently sound and morally acceptable, but every move in this direction must be met and counterbalanced by engineering science. And, finally, I state in all earnestness, that progress in the automobile industry can only be maintained and increased by strenuous and continuous efforts on our part, by science and sound technique of manufacture, to reduce the cost of production to such an extent as to allow us to establish and maintain the enormous growth of business which we and the world at large have every right to expect.

SIXTY YEARS AGO.

IT was recently asserted in all solemnity that one of Columbus's ships was still in existence and actually in service as recently as the 1890's. Historically there is no evidence which might be advanced to disprove the tale. On his four voyages of discovery Columbus employed a total of thirty vessels—or perhaps twenty-nine, for the "Nina" seems to have taken part in the second as well as the first voyage. In addition to these vessels under Columbus's own command, numerous supply ships were despatched from Spain during his lifetime, which, although in charge of subordinates, might still reasonably be called his. Of the fate of all these vessels our knowledge is not sufficiently complete to enable us to assert positively that none did or could have survived until the end of last century. The physical improbability of such survival is, however, so great as to amount almost to complete certainty that the tale is false. Possibly it arose as a result of some self-deception on the part of an impressionable person who saw afloat, a few years only after it had been built, one of the replicas of the great discoverer's ships constructed in connection with the celebrations of the four hundredth anniversary in 1892. Credulity is apt to be strained by stories concerning the survival of old ships. We can, however, readily believe that sixty years ago there still existed in a seaworthy condition a ship built in 1764. This vessel, the barque "Truelove," was, according to a note in our issue of October 10th, 1873, built on the Delaware, probably at Kensington. She was constructed for owners residing at Hull, England, and in 1873, under the command of Captain Thomas Wetherill, was still sailing from that port. For forty-seven years she had been engaged in whaling in the northern seas. She was of 296 registered tons and, in spite of her 109 years, had never required any considerable repairs. Her original timbers, it was stated, appeared to be as sound as on the day she left the stocks. This last statement is perhaps the most interesting fact recorded about the old vessel. When we hear tales of the survival of ancient ships we ought, before giving them full belief, to inquire to what extent the fabric which has survived is the original structure and how much of it is of less remote age. The "Truelove" has doubtlessly now disappeared from the seas. The "Victory," built about the same year, survives, but of her original timbers little remains following the rebuildings which she experienced during her active service, the vandalistic reconstruction of the Victorian period, and the careful loving restoration work of our own day.

SOUTH-EASTERN Nebraska Power District, plans for which have been approved by the State Department of Public Works, would involve 600 miles of transmission lines for rural service to farmers unable to secure energy from existing companies.

Resistance to Wear of Nitrogen-Hardened Cast Iron.*

By J. E. HURST (Sheffield).

Some properties of an aluminium-chromium alloy cast iron and its behaviour when subjected to the nitrogen-hardening process have been described by the author in a previous paper.† It was shown that alloy cast irons of this type, when exposed to an atmosphere of ammonia gas under the conditions of the commercial nitrogen-hardening process, undergo a surface-hardening effect. A maximum surface hardness of approximately 1000 Firth diamond hardness was obtained, with a depth of penetration of the hardening effect of 0·018in.

The most important applications of cast iron surface-hardened in this manner are those in which the conditions call for resistance to wear. Of these, cylinders and cylinder liners for various types of engines, pumps, and compressors form a group in which the resistance to wear is a property of considerable industrial importance. Accordingly, the experiments on the resistance to wear of nitrogen-hardened cast iron were arranged to study the behaviour of these materials under wear conditions such as exist in internal combustion engine cylinders. It is necessary to point out that these experiments are not concerned with the investigation of the nature and causes of cylinder wear in such engines, but solely with the determination of the comparative resistance to wear of nitrogen-hardened cast iron under these conditions.

In deciding upon the experimental procedure, it was considered that the available types of abrasion wear-testing machines were not likely to give results which would be of value in determining the comparative resistance of materials to cylinder wear. It was arranged therefore to make experimental determinations under actual engine cylinder conditions. Whilst by this method actual industrial conditions can be duplicated with certainty, the tests are of prolonged duration, since it has been found that considerable engine running or mileage is necessary to provide wear figures of a sufficiently decisive character. These experiments with the object of determining the comparative resistance to wear of nitrogen-hardened cast iron were commenced in the early part of the year 1929, and have been in continuous progress for practically four years.

Experimental Procedure.

The experimental programme decided upon involved the determination of comparative rates of wear in a stationary engine installed in the works. In view of the fact that results obtained from stationary engines are not necessarily similar to those obtained from engines running under actual service conditions, the experimental programme was augmented by the inclusion of similar tests on engines actually in service.

The stationary engine tests were carried out on a Leyland four-cylinder 4in. bore petrol engine of the standard type as used in one of their vehicles. This engine, mounted on a suitable frame, was coupled through the clutch direct to a D.C. current generator. The current generated was taken in parallel with the main works D.C. supply at 230 V, and provision was made in the switchgear to isolate to the test engine those sections of the works plant which would provide a steady load for the generator. In addition, the engine was fitted with a governor.

All the tests were carried out on the material in the form of cylinder liners of the type known as dry liners. These dry liners were pressed into the bores in the cylinder block suitably machined to receive them. They were retained in position by reason of the circumferential stresses due to the "interference fit" allowance provided. The full dimensions of the test liners are shown in Fig. 1. The methods of fitting and the interference fits adopted followed the common practice of lining such engines for ordinary industrial service. Every precaution was taken to ensure regularity and uniformity in the methods and details of the fitting and finishing operations. The bores of the cylinder liners were rectified and brought to standard dimensions by grinding or honing after the liners had been pressed into position in the cylinder blocks.

For test purposes the engine was provided with special aluminium alloy pistons made under controlled conditions from the same cast of alloy. The chemical composition and hardness of this, determined on a sample taken from an actual piston, were as follows :—

Copper	2·0%
Zinc	Nil
Iron	1·48%
Nickel	1·02%
Silicon	1·22%
Magnesium	1·46%
Titanium	0·14%
Brinell hardness	75·5 to 82 Firth (120-kg. load, 4 mm. ball)

The piston rings and scraper rings were specially prepared from a series of centrifugally cast piston ring drums of uniform composition and properties. The rings used for each test were selected as giving a uniform radial pressure. The chemical composition and properties of the piston ring material are given below, and were determined on rings taken from the actual drums used :—

Total carbon	3·23%
Combined carbon	0·65%
Graphite	2·58%
Silicon	2·07%
Manganese	0·92%
Sulphur	0·06%
Phosphorus	0·70%
Nickel	Nil
Chromium	Nil
EN value	$16 \cdot 8 \times 10^6$ lb. per sq. in.
Tensile strength	19·7 tons per sq. in.
Brinell hardness	238

The procedure followed in an individual test consisted of fitting up the four bores of the engine with liners. In one bore a liner of one of the standard materials was fitted, and in the remaining three bores were fitted liners of the materials to be tested. The engine was then run under steady, approximately full-load conditions for a given number of revolutions. Each unit test consisted of a period of 40×10^6 engine revolutions. This period corresponds to approximately 10,000 miles of road travel of this particular engine on the basis of an average of 4000 revolutions per mile, when in the vehicle for which it was designed. All tests were carried out for this or multiples of this period.

FIG. 1

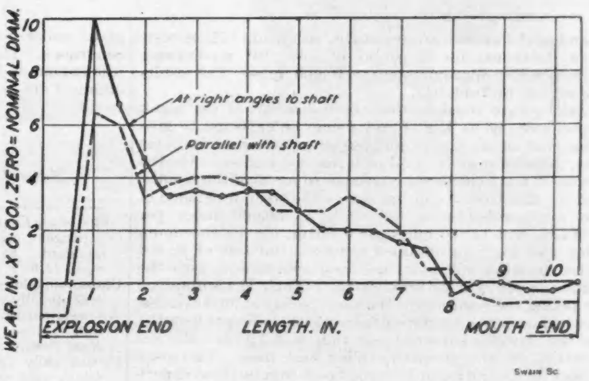

FIG. 2

The amount of wear in each cylinder bore was determined by a comparison of the maximum diameter after the test with the original diameter of the cylinder bore. This difference in diameter is regarded as the maximum wear, and following a common and well-understood practice in cylinder wear measurement is expressed in miles per thousandth of an inch of wear. In the case of the stationary engine tests, this value is obtained by converting the total revolutions into miles, using the relationship referred to previously. The total miles divided by the maximum wear expressed in thousandths of an inch gives the wear value. Expressed in this form the results are comparable with other cylinder wear measurements taken under commercial conditions.

	—	Riley	2·24	0·74	1·50	2·02	0·85	,,	,,	—	0·69	1·80	22·9	27·5	1050
	—	Star	2·29	1·12	1·17	2·25	0·78	,,	,,	—	0·75	1·79	22·5	29·1	989

The measurement of the cylinder bore diameters was made by means of a two-point cylinder bore measuring gauge of a pattern in common use for the purpose. The dial gauge reads differences in bore diameters direct to a graduated accuracy of 0·0005in., and the fraction 0·00025in. is quite easily estimated. In actual measurement the cylinders are explored by means of the instrument to find the maximum diameter. This is to be found generally at or near the diameter at right angles to the crank shaft on a plane passing through the top limit of piston ring travel. In addition to recording this maximum diameter, measurements were made at successive planes, ½in. apart, down the full length of the cylinder bore. The change in these diameters due to wear, expressed in thousandths of an inch and plotted, yields a complete cylinder bore wear diagram, of which a typical example is illustrated in Fig. 2. These curves show clearly the location of the maximum wear, and for the purposes of this comparative investigation the maximum wear values only have been used.

Materials.—Four standard types of materials have been used as a basis of comparison as follows :—

(1) Plain, unalloyed centrifugal cast iron complying with B.S.I. Spec. 4K6.

(2) Chromium alloy cast iron, centrifugally cast, in the as-cast condition.

(3) Chromium alloy cast iron, centrifugally cast, in the hardened and tempered condition.

(4) Nickel-chromium alloy cast iron, centrifugally cast, hardened and tempered to a Brinell hardness of 450 to 500.

The chemical composition and mechanical properties of these materials, determined in each case on specimens taken from the actual cylinder-liner castings, are included in Table I. In the same table particulars of the nitrogen-hardened cast irons used in each of the experiments are recorded.

Blank Experiments.—At the outset of the experiments it was considered advisable to ascertain the degree of uniformity of the maximum wear of the cylinder bores in each of the four bores of the engine. For this purpose the engine was equipped with four of the standard plain unalloyed centrifugal cast liners, standard pistons and piston rings. After 40×10^6 revolutions (10,000 miles) the maximum wear values were determined. The results are given below for each of the cylinder bores, starting from the radiator end of the engine :—

Bore No.	Max. diametral wear, inch.
1	0·00125
2	0·002
3	0·002
4	0·00175

Cylinder bores Nos. 2 and 3 gave uniform results, whilst bores Nos. I and 4 indicated a slightly less amount of wear to the extent of 0·00075in. in bore No. 1. This tendency for bores Nos. 1 and 4 to show a slightly lower wear value may be borne in mind in considering the further test results.

Experimental Results.

Stationary Engine Tests.—In the stationary engine trials Nos. 2, 3, and 4, the results of which are summarised in Table II., the engine was equipped with a liner of standard unalloyed centrifugal cast material in bore No. 3, and a nitrogen-hardened cast iron liner in bore No. 2. These bores were chosen for this test as having given uniform wear in the blank experiment. The chemical compositions and properties of these materials are given in Table I. The engine was opened up for examination and wear measurement after 10×10^6, 40×10^6, and 120×10^6 revolutions, corresponding to the approximate

* The Iron and Steel Institute, September 14th.

† *Journal* of the Iron and Steel Institute, 1932, No. I., page 223.

mileages of 2500, 10,000, and 30,000 respectively. The engine was run at an average speed of 1600 r.p.m. when running under full-load conditions and developed under these conditions an average current of 120 ampères. The engine was equipped with standard aluminium alloy pistons, piston and scraper rings. The maximum wear results are given in Table II.

A further series of stationary engine tests, Nos. 7, 8, 9, and 10, were made with the object of determining the resistance to cylinder wear of nitrogen-hardened cast iron in comparison with that of chromium alloy cast iron. The engine was equipped with two further nitrogen-hardened cylinder liners and two liners of centrifugally cast chromium alloy cast iron. The compositions and properties of these materials are recorded in Table I. The engine, equipped with standard aluminium alloy pistons, piston and scraper rings, was run under conditions similar to the previous tests, and was opened up for examination at the various stages recorded. These tests were continued for a period of 160×10^6 revolutions, corresponding approximately to 40,000 miles. The results are set out in Table III.

Table III.—*Stationary Engine Tests Nos.* 7, 8, 9, *and* 10.

Bore No.	Material.	Maximum wear in inches after—				Wear in miles per 0·001in. after 160×10^6 revs.
		40×10^6 revs.	80×10^6 revs.	120×10^6 revs.	160×10^6 revs.	
1	Nitrogen-hardened cast iron	+0·00075	+0·00075	+0·001	+0·001	40,000
2	Chromium cast iron	+0·00125	+0·002	+0·00325	+0·00325	12,300
3	Nitrogen-hardened cast iron	+0·00075	+0·00075	+0·00125	+0·00125	32,000
4	Chromium cast iron	+0·00125	+0·001	+0·002	+0·0025	16,000

Taking into consideration the indication of the blank experiment, bores Nos. 1 and 4 may be expected to give somewhat higher results, and the values obtained for bores Nos. 3 and 4 may be used as a fair comparison. On the whole, it was considered advisable to average the results, and on this basis mean values for the wear resistance of the nitrogen-hardened cast iron of 36,000 miles per 0·001in., and 14,150 miles per 0·001in. for the chromium alloy cast iron are obtained after the full test of 40,000 miles duration. A more accurate comparison with the results obtained in the previous tests (Table II.) is obtained by taking the results over the same period of 30,000 miles, in which case the mean results are 27,000 miles per 0·001in. for the nitrogen-hardened cast iron, and 12,125 miles per 0·001in. for the chromium alloy cast iron. The mean values for the nitrogen-hardened cast iron in these experiments confirm those obtained in the previous experiments (Table II.), and they show also that the chromium alloy centrifugal cast iron gives results very little different from those of the unalloyed centrifugally cast material.

Road Tests.—In the two road tests recorded, the resistance to wear of nitrogen-hardened cast iron was determined in comparison with chromium alloy and nickel-chromium alloy cast irons in the hardened and tempered condition. The composition of the materials used are recorded in Table I., and the hardened and tempered materials were quenched in oil from 875 deg. Cent. and tempered in a salt bath at 375 deg. Cent.

In the first of these two tests a Riley six-cylinder car was used and fitted with dry liners, three of nitrogen-hardened cast iron and three of hardened and tempered chromium alloy cast iron. The fitting of the liners was carried out under the same conditions as in the case of the stationary engine. The engine was run under ordinary road service conditions for a total distance of 44,500 miles, and the wear test results then obtained are given in Table IV.

Table IV.—*Road Tests (Riley Six-cylinder Car).*

Bore No.	Condition of material.	Maximum wear after 44,500 miles, inch.	Miles per 0·001in. wear.
1	Hardened and tempered ..	+0·0115	3,870
2	Nitrogen hardened	+0·0085	5,250
3	Hardened and tempered ..	+0·010	4,450
4	Hardened and tempered ..	+0·0085	5,250
5	Nitrogen hardened	+0·00275	16,200
6	Nitrogen hardened	+0·005	8,900

For approximately the last 15,000 miles of this test the engine was run on fuel doped with Ethyl Fluid. This was done with the object of ascertaining whether the use of this fuel had any deleterious effect on the nitrogen-hardened material. No sign of any effect was to be observed in any of the cylinder bores.

The amount of wear in each of the nitrogen-hardened liners in this test varied substantially, and most probably this is due to the fact that the liners had been protected from the hardening effect somewhat irregularly. The protection of the internal edge of the liners at the explosion end had been allowed to extend sufficiently far into the bores to be definitely beyond the top limit of piston ring travel. This was quite clearly the case in bore No. 2, and was discovered only when the test was well under way. The mean wear results from this test, however, gave the following values for each of the two materials :—

Chromium alloy cast iron, hardened and tempered : 4,520 miles per 0·001in. wear.
Nitrogen-hardened cast iron : 10,100 miles per 0·001in. wear.

Table V.—*Road Tests (Star Six-cylinder Car ; Wet Liners).*

Bore No.	Condition of material.	Maximum wear after 10,070 miles, inch.	Miles per 0·001in. wear.
1	Hardened and tempered ..	+0·00325	3,300
2	Nitrogen hardened	+0·0005	21,400
3	Hardened and tempered ..	+0·00325	3,300
4	Nitrogen hardened	+0·0005	21,400
5	Nitrogen hardened	+0·00075	14,250
6	Hardened and tempered ..	+0·0035	3,050

The second road test was carried out on a six-cylinder Star engine fitted with "wet" liners. As in the former test, three nitrogen-hardened and three hardened and tempered liners were fitted. The liners were fitted to the engine by the makers. In this case the hardened and tempered liners used were made with a nickel-chromium alloy cast iron of a composition as given in Table I. This test was run under road service conditions over a distance of 10,070 miles, and the results obtained are set out in Table V.

The mean wear values for each of the materials in this test are :—

Nickel-chromium cast iron, hardened and tempered : 3,220 miles per 0·001in. wear.
Nitrogen-hardened cast iron : 19,020 miles per 0·001in. wear.

Summary.

The comparative resistance to wear of nitrogen-hardened cast iron and several other types of cast iron was investigated under internal combustion (petrol) engine cylinder conditions. The experiments were made on a stationary test engine and under road test conditions. The results obtained are summarised in Table VI.

Table VI.

Material.	Total mileage.	Wear, miles per 0·001in.	Total mileage.	Wear, Miles per 0·001in.
Stationary Engine Tests.				
Centrifugal cast iron, standard to B.S.I. Spec. 4K6	30,000	12,000	—	—
Chromium alloy cast iron, centrifugally cast ..	30,000	9,250	40,000	12,300
Nitrogen-hardened cast iron	30,000	24,000	40,000	32,000
Road Tests.				
Centrifugally cast chromium cast iron, hardened and tempered ..	—	—	40,000	4,520
Centrifugally cast nickel-chromium cast iron, hardened and tempered	10,000	3,220	—	—
Nitrogen-hardened cast iron	10,000	19,020	40,000	10,100

A strict comparison of the results can be made only on the basis of equal mileages. At a mileage of 30,000 in the stationary engine tests, a comparison can be made between nitrogen-hardened cast iron, standard centrifugally cast and chromium alloy cast iron. At this mileage the ratio of the resistance to wear of nitrogen-hardened cast iron to standard centrifugally cast iron is as 2 : 1, and to chromium alloy cast iron as 2·6 : 1. At a mileage of 40,000 the ratio of the nitrogen-hardened to the chromium alloy cast iron still remains the same at 2·6 : 1.

In the tests under road conditions, the wear value in miles per 0·001in. of wear is smaller in magnitude than under the stationary engine conditions, but at a mileage of 40,000 the ratio of the nitrogen-hardened to the hardened and tempered chromium alloy cast iron is 2·2 : 1, a figure which is in close agreement with the stationary engine tests. The ratio at 10,000 miles is much higher in favour of nitrogen-hardened cast iron, but in view of the comparatively short duration of this test the results are omitted from this summary.

It is a matter of general interest to note that the differences between the wear values of ordinary cast iron, alloy cast irons, and hardened and tempered cast irons of the types experimented with are not of a very large order.

These results demonstrate clearly the improved resistance to wear under internal combustion (petrol) engine cylinder conditions of cast iron surface hardened by the nitrogen-hardening process. They also may be used to demonstrate the stability of the nitrogen-hardened surface under these same conditions.

In a short test using petrol doped with Ethyl Fluid, no effect due to the presence of the Fluid was observed.

Permission to publish these results has been granted by the directors of the Sheepbridge Stokes Centrifugal Castings Company, Ltd., in whose laboratories these investigations were carried out.

The French Shipping Exhibition.

The annual Salon Nautique, or Shipping Exhibition, which was opened last week on the bank of the Seine in Paris, was originally promoted by boat and engine builders with a view to stimulate public interest in cruising on the extensive system of inland waterways in France, and owing probably to the popular character of the gathering the heavy branch of marine engineering has of late years abstained from taking an active part in it. With the exception of a powerful Lorraine unit with engine of the aviation type and the compression-ignition engines of the Société Als-Thom, the Anglo-Belgian Company of Ghent, and one or two others, the engines are generally of medium and small sizes and the number of them exhibited appears to have declined, as the result, apparently, of the general abandonment of petrol as a fuel for other than the smallest power units. The British industry is represented by the Ruston-Lister Marine Company and by Petters Ltd., of Yeovil. Being the only exhibition of its kind in France, the Salon Nautique offers an opportunity to British marine engine builders to get into touch with a market which should become increasingly important when the economic situation begins to improve. It appeals more particularly to private boat owners, with whom there is obviously less to be done than in some other directions, notably the fishing fleet, to which some prominence is given by the Ministry of the Merchant Marine, and a participation in the Exhibition may be regarded as a useful introduction to shipping generally. The latest figures given by the Ministry of the Merchant Marine of the tonnage of motor propelled fishing boats cover 1931, when it amounted to 55,564 tons. Since then the fishing fleet has fallen on bad times and the fitting of engines to boats has proceeded slowly, though the equipment of existing boats with new engines offers plenty of scope for business in the future. Nowadays, fishing boats have to go much farther afield than formerly.

In the same way, the strike of bargemen on the northern canals has revealed the advantages of self-propelled barges with their greater economy and accelerated transport. At one time several makers, principally Belgian, exhibited engines of the outboard class for the conversion of existing barges, the engine being contained in a well astern with the transmission and propeller carried outboard and generally capable of being raised when passing through locks, but this transformation of barges has not met with any particular success, for the reason that few owners of single barges are able to bear the cost of fitting a power equipment, while there is obviously an economy in building bigger barges for engine propulsion. The canal navigation companies are putting into service a larger number of oil-engined barges, and the ranks of private motor barge owners are increasing, and will continue to increase when the State is able to offer greater financial facilities to owners for the purchase of self-propelled boats. The business is mainly in the hands of Belgian and Dutch engine builders, and French makers are now in competition with compression-ignition types of marine engines, mostly constructed under foreign licence. As an organisation at the ports is essential to the supply of engines for fishing boats, so something of the kind is needed at inland ports for the power equipment of barges.

Small outboard units with petrol engines have become increasingly popular for canal and river pleasure craft, and the number of exhibitors is larger than ever before, including United States, German, Swiss, and French makers, these last-named having abandoned their original types of small units and fallen into line with the universal pattern of outboard propelling gear. So far as boat building is concerned, the Salon Nautique, while not extensive, shows much that is of interest, and some models of yachts are exhibited by John I. Thornycroft and Co., Ltd., who have recently obtained orders for five yachts from French customers.

Methods of fire protection on board ship are an outstanding feature of the exhibits of shipping companies which seek to restore confidence, which was badly shaken by the disasters of the past few years. Several firms showing processes for rendering wood fireproof, and so far as can be judged from the way in which the problem is dealt with there is no question of substituting other materials for wood, except for the use of metallic framework, such as is observable in a ship's cabin shown by the Société Provençale de Constructions Navales as a replica of cabins installed on the latest liners constructed in the company's yards. Everything depends upon the treatment of the wood, linoleum, and textile hangings. Samples are shown of wood impregnated throughout and subjected to successive fires, high temperatures, and the application of the blow-pipe, and holes burnt through wood partitions left charred edges without any outbreak of fire. Varnishes are shown that are claimed to be incombustible. The Chantiers de Penhoët exhibit models of the devices they employ for testing the fireproof qualities of materials and display graphs indicating the number and character of the tests they have carried out during the past eighteen months. They also show systems of metallic supports for electric cables. The last year or so has been devoted to a close investigation by State Commissions and the shipping companies into all possible methods of eliminating the risk of fire on board ship, and it is sought to convince the public that this object has now been attained.

Work recently completed in the way of harbour extensions and improvements is indicated by models of the ports of Cherbourg, Dunkirk, and Boulogne ; representations of the "Normandie," as she will be afloat, impress the public with the progress of the French merchant marine, and models of new cruisers shown by the Ministry of Marine, a model of a testing tank, and other exhibits representing what has been accomplished in the maritime services are well presented as a means of stimulating popular interest in them.

CHADWICK LECTURES.

The programme of Chadwick Public Lectures, which are open to all, starts on Monday, October 23rd, at 5.15 p.m., at the Royal Society of Arts, Adelphi, with a lecture on "Port of London Sanitary Administration," by Mr. P. W. Coombe, a Port Sanitary Inspector who has a fine series of slides to illustrate his subject.

The second lecture will deal with the "Sanitary Arrangements of Mediæval Monasteries." Dr. Percy Flemming has devoted much time and enthusiasm to the study of early monasteries as self-contained units of civil life. He will show on the screen examples of monasterial sanitation as discovered at Canterbury, Westminster, Gloucester, Fountains, Furness, and other abbeys. It will be delivered on Thursday, November 2nd, at 5.30 p.m., in the hall of the Royal Society of Tropical Medicine and Hygiene, 26, Portland-place, W.1.

In the same meeting place, the "Malcolm Morris Memorial" lecture will be delivered on Tuesday, November 14th, at 5.30, by Dr. R. O. Moon, the subject being "Housing and Town Planning in Relation to Public Health."

A variation of the usual type of Chadwick Lectures will be the "Bossom Gift" symposium on "The One-pipe System of House Drainage in Theory and Practice," to be held at the London School of Hygiene, Keppel-street, Bloomsbury, on Tuesday, November 21st, at eight o'clock.

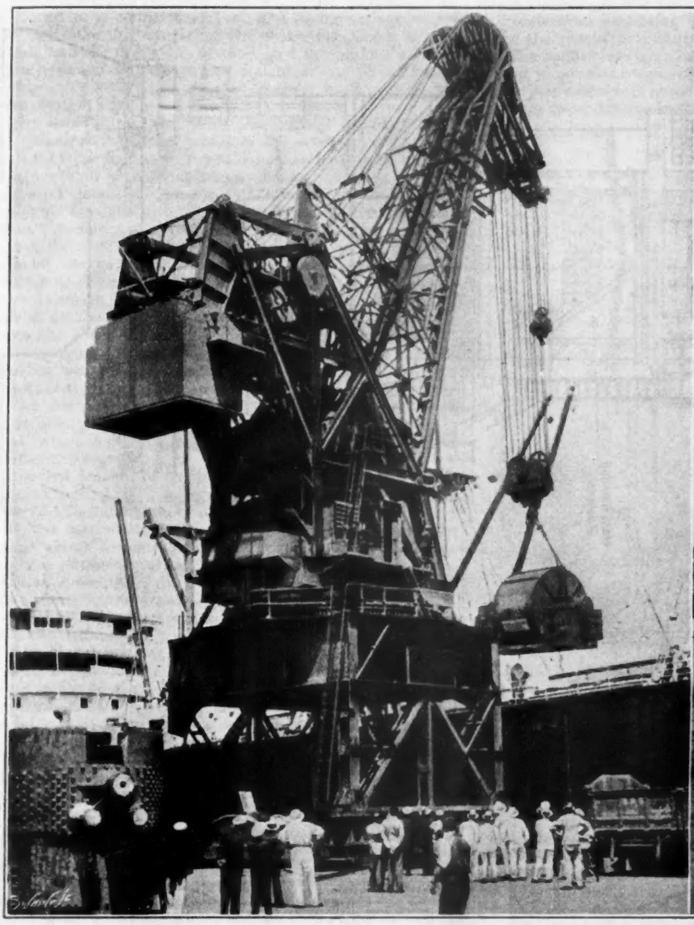
The programme will terminate with an address on "Rural Sanitation," by Mr. J. H. Coste.

A lecture out of London will be delivered by Mr. E. G. Haygarth Brown, formerly of the Ministry of Agriculture, who will discourse on "Standards of Food in Relation to Public Health," at the University of Reading.

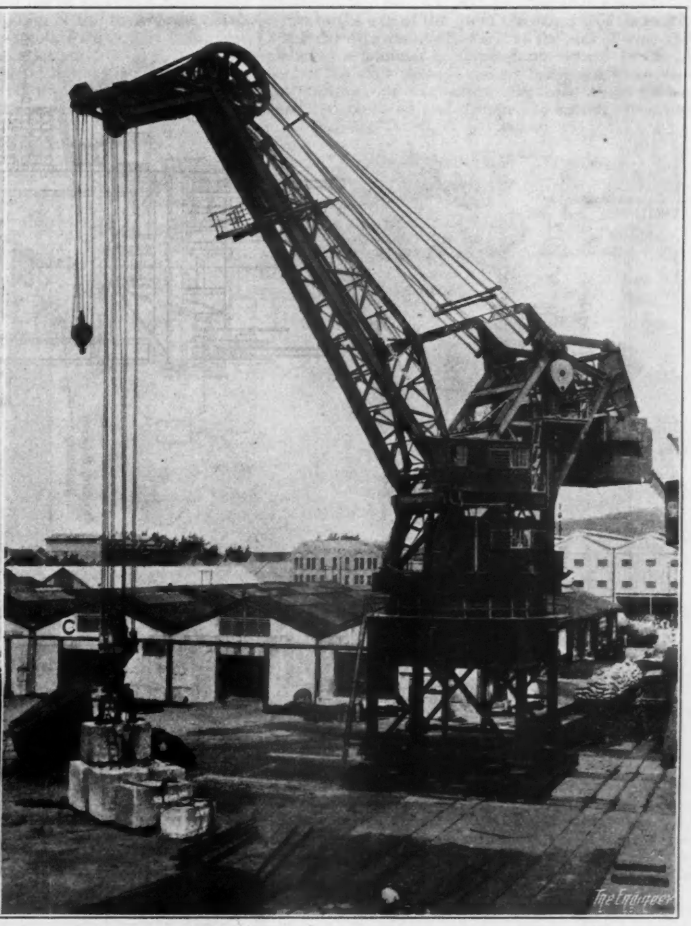
Further particulars of these and future Chadwick Lectures may be obtained from the Secretary, Mrs. Aubrey Richardson, 204, Abbey House, Westminster.

80-TON ELECTRIC LEVEL-LUFFING JIB CRANE

BABCOCK AND WILCOX, LTD., LONDON AND RENFREW, ENGINEERS



LIFTING A 60-TON MOTOR



AN ACCEPTANCE TEST

An 80-Ton Level-Luffing Travelling Crane

◆

ALTHOUGH it is some years since we dealt in full with the special type of level-luffing lever jib crane, designed and built by Babcock and Wilcox, Ltd., of London and Renfrew, one of these cranes was briefly described in our issue of March 30th, 1931. It was a 20-ton portable crane for harbour and railway work. The crane we are about to describe is the largest of its kind yet constructed, having a lifting capacity of 80 tons, and was built to the order of Reynolds, Sons and Partners (Proprietary), Ltd., for the South African Railways and Harbour Administration. After undergoing official tests at the makers' works, it was dismantled and re-erected at Durban, finally tested, and is now available for the service of the port.

As our drawing and engravings indicate, it is arranged to travel on an 80ft. long track of four lines of rails, which are laid at right angles to the face of the quay wall, the actual length of travel of the crane being 53ft. The rails are sunk slightly below the surface of the ground, so that the crane when not required can be travelled away from the quay wall and the ordinary railway track for wagons, which is parallel to the quay side, can be restored by fitting in it removable pieces of rail at the points where it crosses the four-rail crane track. The quay is thus free for the passage of smaller cranes and railway wagons used in working cargoes. This arrangement is indicated in the view on the right reproduced above, which shows the crane undergoing acceptance tests at a point about midway along its track. The view to the left of the same illustration shows the crane in the alongside-ship position, lifting a 60-ton motor.

Hoisting Gears.

The main hoisting machinery is designed to lift the maximum load of 80 tons at the rate of 5ft. 9in. per minute on the main return block with ten falls of steel wire rope, while a load of 40 tons can be similarly hoisted by means of change speed gear at a speed of 11ft. 6in. per minute. The hoisting rope winds on a mild steel welded barrel, 6ft. diameter and 11ft. 6in. long, which is grooved to receive the rope. An overload prevention device, illustrated by a diagram, and referred to later, is provided in order to ensure that loads above 80 tons cannot be lifted, and also that the maximum load of 80 tons cannot be luffed out beyond a radius of 62ft. 6in.

The auxiliary hoisting return block is designed to lift 20 tons on six falls of rope at 24ft. per minute, or 10 tons at 48ft. per minute, by means of change speed gear. The motors for both the main and auxiliary hoisting motions are 50 B.H.P. series-wound machines, and run at 600 r.p.m. Each of the hoisting controllers, which are of the tramway reversing pattern, has dynamic braking on the lowering side, and, in addition, each motion is equipped with a powerful mechanical brake, apart from the automatic magnetic brake on the motors.

The crane is designed to luff with the full load at 60ft. per minute from minimum to maximum radius, and the luffing machinery comprises a 30 B.H.P. compound-wound motor running at 750 r.p.m., which operates the motion through a train of spur gears.

Slewing Gear.

The crane is arranged to slew at the rate of one-third revolution per minute, through spur and bevel gear reductions driven by a 35 B.H.P. motor running at 650 r.p.m. The main pinion gears with the slewing rack built up of mild steel sections, the teeth being formed from renewable high tensile steel pins with rollers. The motion is provided with a powerful foot-operated mechanical brake and a slipping clutch. The racepath consists of a live ring of rollers running between two machined bevelled paths, the lower of which, forming a complete circle, is mounted on the travelling understructure.

OVERLOAD PREVENTION DEVICE

Travelling Gear.

In order to facilitate easy travelling, each of the four legs of the undercarriage is mounted on a bogie with a ball and socket joint, the four bogies being furnished with sixteen central flanged rail wheels, eight of which are driven through spur reduction gear by a 35 B.H.P., 650 r.p.m. electric motor. This drive is designed to travel the crane, without the load, at a speed of 30ft. per minute. A magnetic brake is fitted to the motor and anchor links and shackles are provided which engage with hooks fixed in the concrete foundations, and so enable the crane to be anchored after it has been moved into position at either end of the track. Two portable blocks, 30ft. long, are provided, which are lowered alongside the undercarriage to prevent wagons running into the crane carriage, when it is across the wagon tracks. The bogies on which the crane travels are 3ft. 6in. gauge and the bogie tracks are 27ft. between centres.

Some idea of the size of the crane may be gathered from the facts that the height from the rail level to the top of the roller path is 28ft., and from the wharf level to the hook when in its highest position 78ft., and the hook can be lowered to a depth of 45ft. below the wharf. The ballast tank at the back of the jib foot may be noted. In order that some existing material at site could be utilised for ballast, a swinging tank was supplied, which holds about 123 tons of scrap, consisting of short lengths of rails and sole-plates. The crane has been designed to be completely stable, when unloaded and when subjected to a wind pressure of 40 lb. per square foot.

Operating and Control Gear.

On the drawing reproduced on page 340 we have indicated the principal positions of the machinery houses and compartments and the inspection and oiling galleries. The driver's cabin, in which is fitted the controlling gear for the hoisting, luffing, and slewing motors, consisting of four controllers, control panel, and levers for the mechanical brakes, is situated about 44ft. above the quay level, and is placed forward of the jib foot, to one side, so that

VIEW FROM ARROW X

under all conditions a clear view of the load being handled is obtained.

The auxiliary hoisting gear is accommodated in a machinery house alongside the driver's cabin, the main hoisting and the slewing gears being arranged in houses about the level of the race path, while the travelling gear is placed in a compartment on the undercarriage where the controller for operating the travelling motor is also fitted. All the gearing is of steel, and the pinions and the main hoisting spur wheel were machined out of mild steel blanks. The structure of the crane is built completely from British steel.

The level-luffing gear is of the makers' familiar type, the principal feature of which is the articulated jib lever with its cam and back guys. Another feature of the jib design which our illustrations clearly show is greatly increased clearance underneath the crane, compared with the usual straight jib. The swinging counterbalance also keeps the centre of gravity near the centre post, and well within the race path under all conditions, as the counterbalance moves inwards as the jib moves inwards, and *vice versâ*. It may also be noted that the counterbalance is mounted on a variable arm, and that there is no fixed ballast at the back of the crane, an arrangement which keeps the centre of gravity much nearer to the centre of the revolving bed-plate at any radius and load than is possible with fixed ballast, while the load on the rail wheels is thus equalised and serves to enhance the safety of the crane. The back guys are eight-fold steel wire ropes arranged to lap over a cam on the back of the jib lever, which is given a large radius to ensure freedom from wear of the ropes.

Another feature of the luffing gear is the use of cranks and connecting-rods, an arrangement which was adopted after full consideration of all other systems on the ground that the harmonic action of the cranks automatically brings about a reduction in the speed of luffing towards the ends of the travel, although the motor is running at a uniform speed, and, further, the jib is positively driven in and out by the cranks.

Another advantage claimed for the design adopted is that the balance of the jib is not affected in any way by the load lifted, and it is in perfect equilibrium from maximum to minimum radius; therefore the power required to move the jib is only that needed to overcome the friction of the moving parts, and a 30 B.H.P. compound-wound motor running at 750 revolutions per minute is quite sufficient to luff the jib easily and safely in either direction, whilst sustaining a load of 80 tons at 60ft. per minute. As shown in the drawing, page 339, an arrangement of self-resetting limit switches is fitted in order to cut off the current when the maximum radius of 72ft. 6in. or the minimum radius of 25ft. has been reached.

The power supply is D.C. current at a pressure of 550 volts, and is brought to the crane by a flexible trailing cable, 60ft. long, with a plug which can be fitted into either of two plug boxes arranged along the track.

The size of the crane we have described will be apparent from our illustrations. It was completely erected at the makers' works, on a temporary rail track carried on concrete foundations, and was fully tested in all its motions with a load of 100 tons, in the presence of the inspecting engineer to the High Commissioner for the Union of South Africa. After testing, it was dismantled and shipped to South Africa, where it was erected and tested under the supervision of Lieut.-Colonel J. Dickson, the mechanical engineer to the South African Railways at Durban, and Mr. C. Nicks. Despite the magnitude of the undertaking, the period which elapsed from the landing of the material to the carrying out of the final test was only three months. The work proceeded without a hitch of any kind, except that it was held up for about fourteen days owing to bad weather conditions. All the various parts went together perfectly, and the test, we are informed, was satisfactory in every respect. The new crane now forms a valuable addition to the services of the Port of Durban.

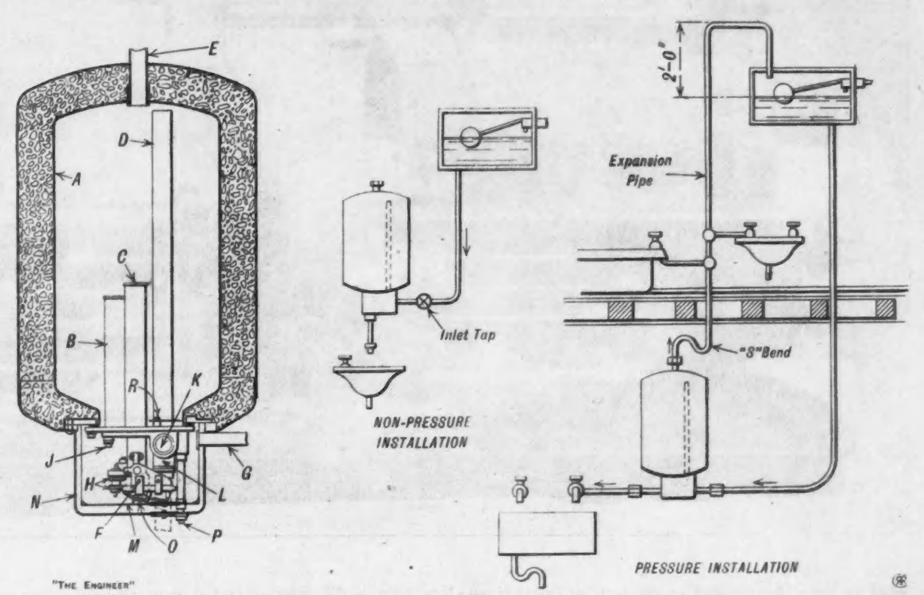
Electric Water Heaters.

Domestic electric water heaters made in sizes recommended by the British Electrical Development Association have been put upon the market by A. Reyrolle and Co., Ltd., of Hebburn-on-Tyne. The standard heaters are cylindrical, but rectangular heaters are also supplied. The range in both cases meets the widest variety of requirements. The rolled sheet copper water container of the cylindrical units has domed ends, all joints being welded. At the top of the container there is an outlet for an expansion pipe, whilst the base is provided with a reinforcing ring which carries the plate supporting the heater and thermostat tube. All surfaces which make contact with the water are heavily coated with pure tin. Inlet and outlet pipes attached to the cast brass apparatus plate have standard threads. The heating element container, and that for the thermostat, are also fitted to this plate, and a screwed plug is provided to enable the tank to be drained. A standard Reyrolle heater unit, consisting of a bobbin shaped porcelain member fixed on a non-rusting central metal rod and resistance wire rated to ensure long life, is used in all cases. By removing two small screws the element can readily be withdrawn from the apparatus without draining the water from the container.

The thermostat consists of a straight invar rod fixed to a brass tube, and the unequal expansion of the two metals causes a mercury switch to trip and make or break the supply circuit. By turning a knurled knob the temperature at which the water is maintained can be varied between the limits of 120–190 deg. Fah. Once the knob has been set for a definite temperature it is retained in position until it is reset. The water container is enclosed in a neat sheet metal enamelled casing and the intervening space between them is filled with granular cork to reduce heat losses to a minimum. Substantial fixing brackets drilled to the standard dimensions recommended by the Electrical Development Association are supplied. All the terminals and connections to the heater and thermostat are properly protected by covers.

The general construction of the cylindrical type of heater will be understood from the section shown in the accompanying illustration, in which A is the inner water container, B the heater tube, C the thermostat tube, D the hot water outlet pipe, E the outlet for the expansion pipe and hot water outlet, F the thermostat mercury switch, G the entry for a ¾in. Simplex cable conduit, H line terminals, J the earth terminal, K the outlet pipe connection, L an alternative outlet pipe and drain plug, M a leatheroid insulating lining, N the thermostat cover, O the thermostat adjusting knob, P the cover fixing nut, and R a baffle plate over the inlet pipe.

As it is not always possible to find a rigid support for a heater just where it is required, a special foundation framework has been designed. It is made of flat mild steel bars and is drilled and tapped to suit specific heaters. The holes for fixing screws can be drilled on site to match points at which a rigid support is possible, such as the wooden bearers of a lath and plaster wall. Alternatively, bolts can be provided for stone or brick walls. The special framework also allows the apparatus to be set perfectly plumb, and when it has once been fixed it can be removed and returned to exactly the same position without damaging the wall. Standard heaters are fitted with two terminals for the supply cable and the protecting covers are designed for cables run in conduit.

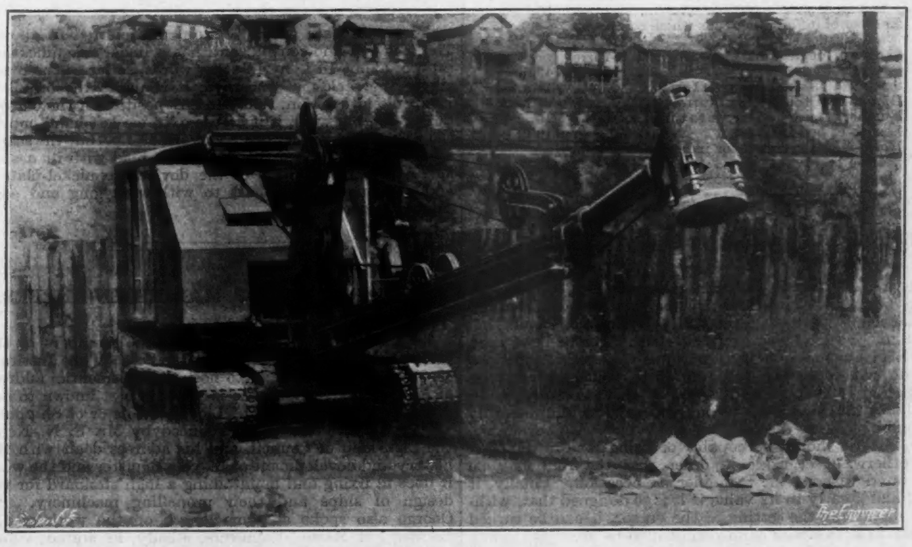


Section Through Electric Water Heater, and Arrangement of Pipe System

Small capacity heaters should be fitted as near as possible to the service point, and as only one outlet is usually required the control tap can be connected in the inlet pipe as shown in the centre illustration. This is known as a "non-pressure" heater installation, as there is no pressure on the water in the heater when the tap is closed. In the case of larger installations with several outlet points the taps are necessarily connected to the outlet pipes and the inlet pipe is taken direct to the heater from the reserve tank, as shown on the right of the illustration. This is known as the pressure system, as the water in the pipes and in the heater is always under pressure.

A Pavement Smasher.

Some time ago we had occasion to refer to a machine which had been developed in this country for such purposes as smashing up pavements and other structures that had to be removed, probably through obsolescence. That machine resembled, in its essential features, a mobile pile driver. Another means of carrying out the same style of work, as well as rock breaking and similar jobs, is illustrated by the accompanying engraving, which comes to us from America.



Excavating Machine Adapted for Rock Breaking

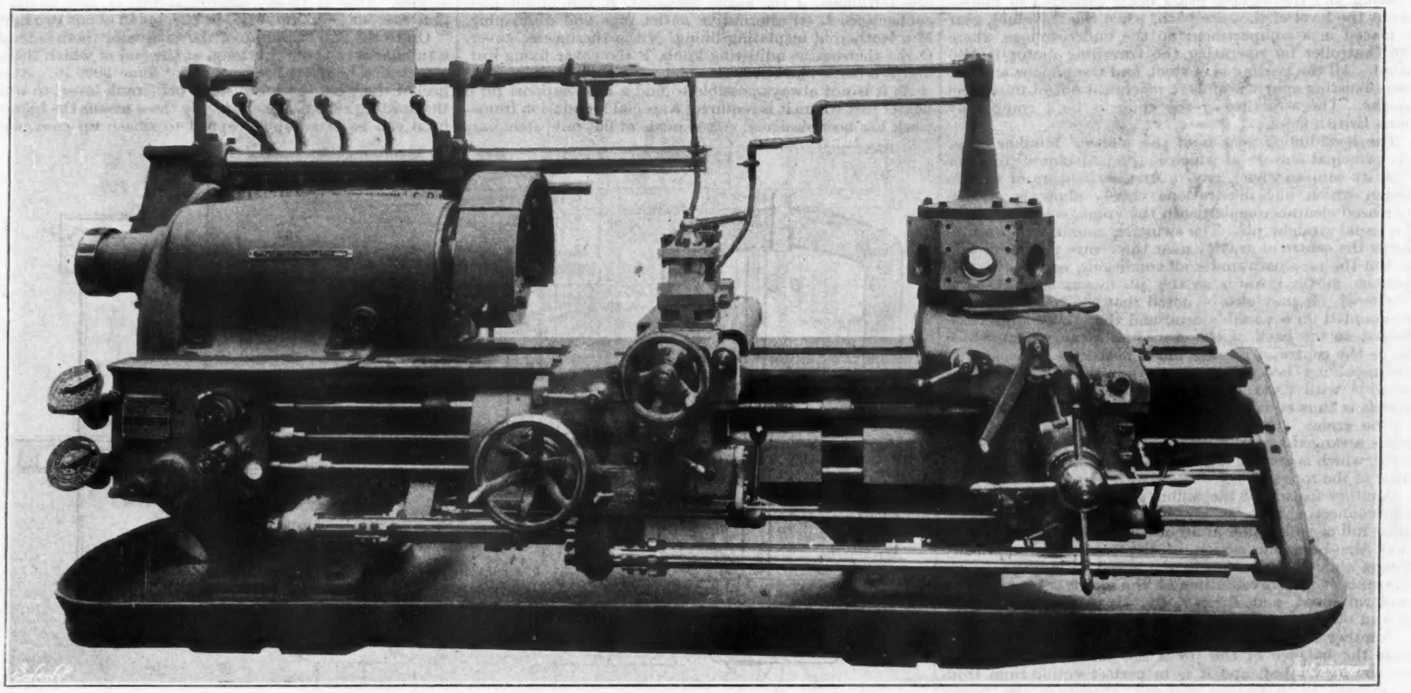
The Keystone Driller Company, of Beaver Falls, Pa., aims at adapting its excavating machines to the utmost variety of purposes, so that, should they be idle in their primary *rôle*, they may be put to work in some other service. One of these transformations is that which we illustrate, and can, it is said, be effected in about two hours.

On to the end of the jib of the excavator there is hinged a tubular arm about 8ft. long, at the end of which there is attached a hammer head weighing some 3000 lb. At the heel of the stalk there is a short bell-crank lever, to which the hoisting rope is attached. By these means the hammer head can be lifted and dropped to smash up pavements, break up stones, and so forth. The free fall of the hammer is facilitated by an easy working clutch on the winch, which is of the V groove type, and the impact of the blow may be accentuated by pulling down on a rope passing beneath the hinge of the arm. We understand that the hinge is of such a design that shocks from the falling hammer are minimised before they are transmitted to the machine. The striking face of the hammer can, obviously, be formed to suit the work in hand. The device is said to be capable of delivering blows from a height of from 5ft. to 10ft. at the rate of twenty a minute.

New Combination Turret Lathe.

Rather less than five months ago we were able to announce that the firm of H. W. Ward, Ltd., of Birmingham, had added another combination turret lathe to the range of such machines it manufactures. The tool we illustrate above is yet another addition, and is known as the No. 8 combination turret lathe. Designed to meet the high-speed heavy-cutting capabilities of modern tungsten-carbide tools, it is especially powerful, but since in many respects it is very similar to other productions of the firm which we have described from time to time, it is unnecessary for us to refer in detail to the various parts. The arrangement of the speed change levers behind the head is retained, together with the mechanism by which a cone clutch in the driving pulley is taken out of engagement and a brake applied to the spindle when one of the levers is in process of being moved. In common with the majority of high-class machines, this lathe is fitted with covered ways. These covers, however, are not of the sliding type, but are held permanently in the one position. Cored passages of a section similar to that of the covers are provided through each saddle. The feed gear-box arranged

NEW COMBINATION TURRET LATHE

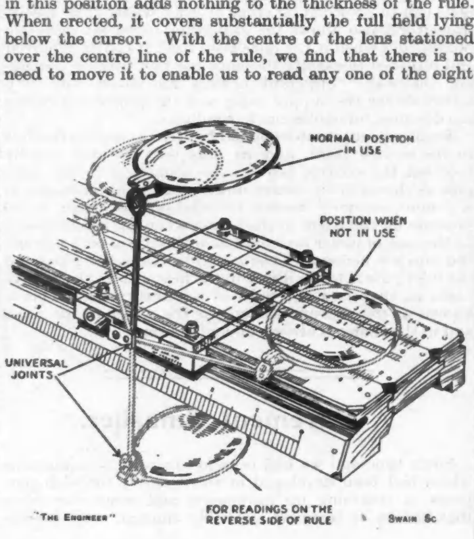


as usual at the left-hand end of the bed, provides three changes of speed for the lead screw, ten changes for the sliding and surfacing feed shafts, and five changes for the turret feed shaft. Safety clutches are included in the feed shafts to protect the machine from accidental damage. A speed change gear on the turret saddle doubles the number of feeds available at this point. Since this change gear has a ratio of about 5 to 1, suitable feeds for such diverse operations as reaming, boring, rough and finish turning can be obtained without altering the setting of the main feed gear-box. All the feed changes can be made while the machine is in motion and the sliding and surfacing and the screw-cutting motions are reversed by the movement of a single lever. The screw-cutting motion is applied to the saddle and is obtained from a detachable leader screw and nut. As the gear-box allows the rotation to be altered in the ratios "equals," two to one, and four to one, with the spindle, it is possible to cut three different pitches with each lead screw. A quick withdraw motion connects the cross slide with the leader nut so that both operate simultaneously. The various parts of the lathe are lubricated by four plunger pumps situated respectively in the headstock, feed gear-box, intermediate saddle apron, and the turret saddle apron. Feed tubes from the pumps in the two saddles spread lubricant on the shears of the bed. Some dimensions of this lathe are given in the following table :—

Height of centre	10¾in.
Swing over bed covers	19½in;
Diameter of chuck which will swing over cross slide..	12½in.
Diameter of chuck or face plate which will swing up to edge of cross slide	17¾in.
Diameter of hole through spindle	3¾in.
Diameter of flange of spindle	10in.
Diameter of driving pulley	12in.
Revolutions per minute of driving pulley ..	600 or 800
Number of spindle speeds in each direction..	16
Swing over top of cross slide of saddle ..	12½in.
Length of longitudinal automatic feed to saddle	43in.
Number of reversible automatic feeds to saddle and cross slide	10
Number of different threads which can be cut with leader supplied	3
Length of longitudinal automatic feed to turret saddle	43in.
Size across flats of hexagon turret..	14in.
Diameter of tool holes in turret	3½in.
Number of automatic feeds to turret saddle ..	10
Length of bed	10ft.
Horse-power required for independent motor drive	15

Slide Rule Magnifying Attachment.

The accuracy with which a slide rule can be read and the comfort with which it can be used are considerably enhanced if the rule is fitted with some form of magnifying system. Various forms of slide rule magnifier have been devised, but most of them are open to certain objections or do not cover the full service to which a magnifier might be applied. The attachment should obviously not be bulky and should cover a considerable field, preferably a field as wide as the width of the cursor. It is desirable, too, that it should be capable of being readily removed or otherwise set aside in order that the rule may be operated without the magnifier on occasion. Finally, it will add greatly to its value if it is so designed that, without disturbing the setting of the cursor, it can be turned about in such a way as to permit it to be used for reading the sine, tangent, logarithm, or other scales on the back of the rule. The magnifier illustrated herewith has just been introduced by A. G. Thornton, Ltd., King-street West, Manchester, and is applicable to the various patterns of P.I.C. rules made by the firm, including the log-log slide rule with differential scale described in our issue of April 7th, 1933. The device is attached to the top edge of the cursor. It consists of a circular lens, 1⅝in. in diameter, mounted on a ball joint at the end of a rod. A similar ball joint at the other end of this rod is employed to attach it to the edge of the cursor. Adjusting screws are provided to enable the friction at the ball joints to be regulated. The lens has an almost completely universal movement. It can be folded down flat against the face of the rule when it is not required, and in this position adds nothing to the thickness of the rule. When erected, it covers substantially the full field lying below the cursor. With the centre of the lens stationed over the centre line of the rule, we find that there is no need to move it to enable us to read any one of the eight scales on the face of the log-log rule referred to above. The lens is plano-convex, and has a linear magnification ratio of about 1 : 1·7. In other words, so far as the reading of the scales is concerned, it converts the ordinary 10in. rule into a 17in. rule. In any position of the cursor, but preferably when it is at the extreme left-hand end of the rule, the magnifier can be inverted to permit the scales on the reverse side of the slide to be read with its assistance. The metal parts of the device are nickel-plated, and are sufficiently robust to withstand long and continuous service.



SLIDE RULE MAGNIFIER

THE INSTITUTE OF MARINE ENGINEERS.

There was a large gathering of the members of the Institute of Marine Engineers at the home of the Institute on Tuesday evening last, to hear the presidential address of Sir George Higgins, who is perhaps best known to our readers as the Chairman of Lloyd's Register of Shipping. The new President was introduced by Mr. S. N. Kent, the Chairman of Council, and his address dealt with the history and development of Lloyd's Register and the work it does in fixing and maintaining a high standard for the design of ships and their propelling machinery. Sir George also spoke at some length on the work of the Institute of Marine Engineers, a body, he stated, which might well be defined as the representative organisation of the marine engineering profession. He congratulated the Institute on its Royal Charter and the efforts it was making to bring its standard of membership in line with those of the senior chartered institutions which represented other branches of engineering activity. The principal papers to be read during the forthcoming session include one by Dr. Ormandy on "Oil from Coal," one by Mr. Robert Sulzer on "Welding for Pressure Vessels," and one by Mr. Stanley S. Cook on "Geared Turbine Installations for Tramp Steamers," all of which, the President stated, would deal with new and important developments in marine engineering work.

PERSONAL AND BUSINESS ANNOUNCEMENTS.

Mr. Leonard Clarke, A.M.I. Mech. E., for many years chief draughtsman of the British Electric Transformer Company, Ltd., Hayes, Middlesex, has severed his connection with that company.

The "Sentinel" Waggon Works, Ltd., of Shrewsbury, have acquired the business of Garner Motors, Ltd., and the Garner range of light petrol vehicles will thus become complementary to the "Sentinel" Steamer range. To cope with this additional work the "Sentinel" plant at Shrewsbury will be extended.

The Brush Electrical Engineering Company, Ltd., Loughborough, announces that Mr. Norman A. Collard has been appointed assistant general manager. Since the war Mr. Collard has been associated with the sales department of Metropolitan-Vickers Electrical Company and the Stirling Boiler Company, Ltd. He joined the sales staff of the Brush Company in January, 1931.

Waygood-Otis, Ltd., announces that Mr. Henry C. Walker, who has been with the company for nearly seventy years, and has been chairman since the formation of the company, is retiring on account of his age, which is just on eighty-three. Mr. D. W. R. Green has been elected chairman in his place, and as a consequence has relinquished his position of managing director, which he has held for about twenty years. Mr. W. W. Weaver, who has been appointed managing director, has been with the company something like twenty-seven years. Messrs. H. Harmsworth and C. H. J. Day, both of whom have been directors for many years, are retiring.

CONTRACTS.

Bastian and Allen, Ltd., Hanwell, have received the contract for the thermal storage system for heating the new showrooms for the Swindon Electricity Department, which are now being built.

Sir Lindsay Parkinson and Co., Ltd., have placed with K. L. Kalis, Sons and Co., Ltd., of London, a contract for dredging and other work involved in the completion stage of the new Grimsby fish dock.

C. A. Parsons and Co., Ltd., Newcastle-on-Tyne, have received an order from the Australian Paper Manufacturers, Ltd., of Sydney, for a turbo-alternator of 3000-kW capacity, complete with surface condensing plant. The set, which is of the "Uniplane" non-basement type, will generate current at 3300 volts and will work with steam at 400 lb. pressure superheated to 700 deg. Fah. Messrs. Parsons have also received orders for two complete geared turbo-generating sets for British paper mills. The turbines in both cases are arranged to pass out steam for heating purposes. One of these sets is of special interest for the reason that the turbine will drive both a 1250-kW alternator and a 1000-kW direct-current generator. Each generator will be ventilated on the closed circuit system.

The Portuguese Destroyer "Lima."—On August 4th we described and illustrated the destroyer "Vouga," which is the first of a flotilla of five designed and constructed by Yarrow and Co., Ltd., of Scotstoun, Glasgow, for the Portuguese Government. She was delivered in June and has created a most favourable impression. During the last fortnight all the trials of the second destroyer "Lima" have been successfully completed, and highly satisfactory results have been obtained in regard to both full speed and fuel consumption. The "Lima" is a sister ship to the "Vouga" and has a displacement of about 1600 tons. Her propelling machinery consists of high-pressure turbines, steam being supplied by Yarrow patented water-tube boilers working at a pressure of 400 lb. per square inch.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

The Steel Cartel and British Merchants.

The difficulties of the European Steel Cartel have scarcely been mitigated by the events of the past few weeks. Merchants in Germany, France, Holland, Belgium, and Great Britain are still displaying hostility towards the new sales policy of the Cartel and its selling comptoirs. Under the Cartel's reorganisation scheme, the works' agents became merchants standing in a favourable position with their works, and naturally have had to try and do a direct business with consumers. Their efforts in this direction have aroused such feeling amongst merchants of long standing that a number of them now place their orders direct with the Continent. This state of affairs has prevailed for some time, but recently negotiations were set on foot with the object of reaching an agreement. The merchants have suggested that the works should reinstate their representatives in Great Britain as genuine works' agents who would be permitted to sell only on net cash f.o.b. terms. The negotiations between the Cartel and the merchants have been proceeding on other questions, and it is understood that they are in a fair way to being brought to a successful conclusion. Apart from the request of merchants referred to above, the Continental steel works have withdrawn their demand that merchants should sell only Continental steel to the exclusion of British material, and have also dropped their condition that the merchants' books should be open to the inspection of the Cartel representatives. Further complaints of the merchants that the Continental steel works will no longer sell them semis, but sell direct to consumers in this country through their selling organisations here, is under discussion, but apparently in this matter the Continental steel makers have adopted the attitude that the present arrangement cannot be altered. On the whole, however, the British merchants seem to be making headway in their negotiations, particularly with regard to the export side of the business.

Pig Iron.

This market is exhibiting a stronger tendency, and consumers appear to entertain fears that a scarcity of some brands of foundry iron may develop. The firmer position of the scrap market is also influencing the demand for pig iron, since some descriptions of scrap iron are in rather short supply and a tightness in this market will naturally lead to the heavier buying of pig iron. On the North-East Coast the demand for foundry iron has been catered for by only two furnaces, the difference between the supply and demand being met by withdrawals from stock. The quantities available for this purpose, however, are rapidly declining, and surprise is expressed that another furnace is not put into operation to meet the call for foundry iron. Another furnace, which it is reported will have a productive capacity of 2800 tons per week, is to be started shortly upon basic iron, but it is expected that later on this will be turned over to the production of foundry. The possibility that pig iron prices will be advanced has also been taken into account, since coke prices are rising and the ore position is not so easy as it has been for a long period. In the Midlands the position is not so firm, since consumption has not yet overtaken the demand. Anticipations that prices for Midland irons will be raised in some districts proved groundless, and at their meeting last week the long-standing figures were reaffirmed by the makers, who quote 62s. 6d. for Northamptonshire No. 3 and 66s. for Derbyshire No. 3 foundry and Lincolnshire and South Staffordshire iron, d/d Black Country stations and subject to rebate. There is a good demand for these irons, especially for Northamptonshire brands, the light castings makers in particular taking good quantities. Most of the big consumers, however, are covered up to the end of this year. Specifications against these contracts are well maintained, but current business consists chiefly of small parcels. In Lancashire the pig iron market has been rather less active than of late. The opening days of October, however, were characterised by a fair volume of buying, and it has yet to be seen whether this will be maintained during the remainder of this month. The engineering trades in Lancashire are not taking quite so much iron as a few weeks ago, but against this there seems to be rather more movement in the demand for iron from the textile machinery makers. In Scotland the market remains steady, both as regards prices and the amount of iron passing into consumption. Business with the light castings industry continues on a good scale.

Semi-finished Steel.

The demand for billets and sheet bars shows no signs of relaxing. For the time being, buying may not be so heavy as in the first part of the month, but there is a steady call against contracts, and this is supplemented by a considerable business in small parcels. As a result, the works producing this class of material in all parts of the country are busy. Competition from the Continent is scarcely heard of, and the prices quoted lately for foreign material have been so near to the British quotations that it has not been worth while ordering Continental material unless Thomas steel was specially required. Many producers are definitely asking £5 5s. for billets, although the official price is unaltered at £5 for 500-ton lots up to 0·25 per cent. carbon, whilst for smaller quantities up to £5 10s. has been quoted. Blooms over 7in. square do not come within the Association price arrangements, and the general quotation for this material is £5 to £5 2s. 6d. d/d. In the Sheffield district small quantities of Continental billets are said to be still available at around the British prices, but here there is an expectation that the latter will be advanced. Business in acid steel billets has not been active, but lately there has been some improvement in inquiry. The demand for carbon quality billets has become rather quieter, but on the whole the producers are well employed. Prices are unaltered, and range from £6 12s. 6d. for 0·42 per cent. to 0·60 per cent. carbon to £8 12s. 6d. for 1 per cent. carbon and up. The quotation for sheet bars also has become firmer, but the Welsh producers are holding their price for tin-plate and sheet bars at £4 15s. d/d. Continental offers of sheet bars, although occasionally made at cheap rates, have not affected this market for some time.

Scotland and the North.

One of the features of the Scottish steel trade is the good deliveries of plates against contracts already in existence. There has also been an improvement in the demand for shipbuilding steel generally, as conditions on the Clyde are better than for some time past, although the greater part of the business reaching the steel works has been from the ship repairing yards. The tube works in Scotland also appear to have passed through the quiet period of a week or two ago, and orders are now coming to hand with fair regularity. The re-rollers are experiencing a moderate demand for sections and hoops, but business with overseas markets is poor and the Scottish price has to be cut to obtain business in competition with English and Continental makers. In the Lancashire market trading has been rather listless lately, but most of the works are operating at a fair rate. It is not expected that the reaction will be of long duration; but, of course, in Lancashire much depends upon the conditions of the textile industry. Few orders for new textile machinery are being given out and some of the engineering firms are poorly off for work. In the lighter branches of the steel industry there seems to be a fair amount of business passing, the call for small bars for bright drawing purposes being particularly noticeable. Business in special alloy steels is expanding, although it has been on a good scale for some time past. The recent slight improvement in the demand for structural steel has been maintained; but some of the constructional engineers are approaching the time when they must obtain fresh orders or reduce their rate of operations. Busy conditions continue to prevail on the North West Coast. At Workington the mills have orders on their books for hoops and strip, and are expecting to remain well employed until the end of the year; operations at the rail mill have slackened. At Barrow the mills are engaged on rails, sleepers and semis.

The Copper Market.

More active conditions developed in the copper market this week, but this may be largely due to the buying which usually takes place at the beginning of the month, particularly when the month opens a new quarter. Concurrently with the better demand for electrolytic copper there was an improvement in business in manufactured copper materials, and some of the export merchants reported that overseas markets were showing more interest. In America the producers have retained their quotation of 9c., but most of the big American consumers appear to be well covered and new business has not been on a satisfactory scale. Considerable disappointment has been caused by the failure of the Russian order to mature. The Soviet Government evidently thought that the time was ripe to buy from the Americans on favourable terms, and commenced negotiations for the purchase of 100,000 tons. Had this deal gone through it would have been a considerable relief to the copper producers, who are holding stocks of over 600,000 tons. The Americans, however, would not agree to the Russian terms of credit, and when the American Government was approached to assist in financing the transaction it declined to help except under a guarantee of credit by the exporters of the copper. The whole matter, therefore, has been shelved for the time being. Russia is a producer of copper, but not on a sufficiently large scale for her needs, and requires to import about 30,000 tons per annum. The European demand has improved slightly, but is still much below normal. The standard market responded to the better conditions in the electrolytic market and prices have advanced over the week. It was generally considered that operators had discounted most of the unsatisfactory features of the position, so that the rise when the improvement occurred was not unexpected.

The Tin Position.

On the publication of the very favourable tin statistics at the end of September the market threw off the listlessness which had been affecting it for some weeks and prices rapidly advanced. The chief point in the statistics was the decrease in the visible supply, which, according to Mr. W. H. Gartsen's figures, was from 33,126 tons to 29,892 tons, a reduction of 3234 tons. The carry over in the Straits also fell by 1378 tons, but the carry over at the Arnheim Smelter in Holland increased by 517 tons, thus making a net decrease in the visible supply and the carry over of 4095 tons. Although these figures had been anticipated, they naturally had an encouraging effect upon the market and led to a revival of speculation, although this was not upon an important scale. American consumers also came into the market, but at the same time reports were current of re-sales in America. Continental buying, although it has improved to a certain extent, is still rather quiet. It is generally considered that the tin restriction scheme has been strengthened by the decision of the Cornish producers to become members of the International Tin Pool. It was announced that originally Cornwall had been offered a quota of 1500 tons, but following negotiations this had been increased to 2200 tons, which the producers had accepted as a reasonable figure. The demand for prompt tin has created a small backwardation, but there have been sufficient warrants circulating in the market to keep it at from 2s. 6d. to 5s. There is, of course, no scarcity of tin at the moment, although the steady reduction in the stocks and the shipments of tin to United States have given the impression that a stringency may develop later on. On the other hand, although it is not known how much tin has been sold by the Pool, it is evident that it controls a considerable tonnage.

Lead.

The position in this market has not materially changed. The consumptive demand for the raw metal remains quiet, although, as is usual, it improved in the early days of the month. The best feature of the market is the continued heavy call for manufactured lead materials, such as pipes and sheets, which are being produced and are passing into consumption in considerable quantities. The manufacturers covered their pig lead requirements in August for some time ahead, but it is probable that if the demand for their products continues on its present scale they will shortly be obliged to come into the market again. The position in the United States is shown by the August statistics to have improved to a marked extent. The stocks of refined lead at the end of the month totalled 160,486 tons, or 10,789 tons less than at the end of July. Production in August was 25,058 tons. The effect of the duties, however, is largely to neutralise this improvement so far as the British market is concerned, since it is adequately supplied by Empire producers, and lead coming from abroad is merely placed in bonded warehouses until it can be re-exported. Changes in the American position, therefore, have only a sentimental effect upon prices in this market. The producers seem quite content to follow the market and to supply consumers at current prices. This is regarded by the market as the most judicious course, and at the present low price of the metal should stimulate its use for industrial purposes. One effect of the low quotation is said to be that production is decreasing, but as it is known that considerable stocks exist in the hands of the producers, this has not yet had any influence upon prices.

Spelter.

For many weeks past spelter has been the steadiest of the non-ferrous metal markets, and this still remains its chief characteristic. Buying by consumers has not been active, but the galvanisers have shown rather more interest in the market. The demand from the brass manufacturers also has been quiet, and most of the works seem to have covered their requirements. A pronounced scarcity of hard spelter has developed, and consumers are relying upon the supplies produced in this country, as the duty payable upon imported hard spelter makes it almost as expensive as virgin metal. Hard spelter is used by the galvanisers in small proportions to obtain the "spangles" upon their sheets which are required by some overseas markets. The difficulties referred to last week, which it was thought might result in the dissolution of the International Zinc Cartel, were smoothed out at the meeting on September 30th in Brussels. The Belgian group had given notice of withdrawal from the Cartel owing to dissatisfaction at the way in which the fines on production in excess of the quotas were levied. Modifications were made to suit the Belgians, and it was unanimously decided to continue the Cartel. This is not the first time that this Cartel has been on the point of dissolution, but it is one of the most efficiently run organisations of this kind, and owes much of its success probably to its policy of regulating production and not interfering with prices. The announcement that the Cartel would be continued was well received by the market, and prices moved upwards. The conditions of the market, however, were not favourable to a sustained advance, although they were sound, and the movement was short-lived.

Average Metal Quotations.

The decline in the prices of metals disclosed by the London Metal Exchange average quotations for September follows a decrease recorded at the end of August. Previous to that month metal prices had for some time shown a strong tendency to rise. Tin is the only metal which has increased in value over the August average, and in this case the rise is £1 13s. 5d. for cash tin, and £1 13s. for three months. Copper prices have fallen to a greater extent than other non-ferrous metals, but, even so, the decrease is not heavy. Cash copper is down by 18s. 8d., and three months by 19s. 3d., compared with August, whilst the average price for electrolytic is lower by £1 18s. 9d., and for electrolytic wire bars by £1 19s. 6d. The steadiness of the lead market is shown by the fact that the average price of lead for shipment the current month is only 5s. lower than the August average, and for shipment the third following month and for the mean quotation the average is down 4s. 6d. and 4s. 9d. respectively. Spelter was even more steady, there being a decrease of only 1s. 2d. below the August average, whilst the average price for three months metal was 3d. above that of August. The average mean was 2s. 10d. down. The official average quotations for September are as follows :—

STANDARD COPPER	Cash	£35	3	7 3/16
	3 Months	£35	7	3 9/16
	Settlement	£35	3	8 3/16
ELECTROLYTIC COPPER		£38	13	10 5/16

French Engineering Notes.

(From our own Correspondent in Paris.)

Trade Arrangements.

Events are developing in a way that indicates a change in the French outlook on the economic situation so far as regards foreign trade. One authority has declared that the French Government made a disastrous mistake when it broke off commercial relations with Great Britain, meaning the imposition of the compensating tax of 15 per cent. at the time Britain went off the gold standard. It was declared that the tax represented only one-half of the subsequent currency depreciation, but it was really more with the various taxes that were added to it, and for certain classes of machinery that are ostensibly free of import duty, such as harvesting machinery, the charges amount to about 50 per cent. of the cost. The compensating tax was, moreover, regarded by British manufacturers as something in the way of a challenge, and as a distinct violation of commercial treaty obligations. The effect of that unfortunate retaliation on Great Britain for leaving gold has certainly been disastrous for French trade, in the sense that it has helped to divert channels of British trade elsewhere and to leave France a permanent loser of much of the business she transacted in what used to be her most important market. Another incident is the attitude of Germany towards the suppression of the import quotas under the system which gave *pro rata* allocations to countries enjoying the most-favoured-nation treatment. Germany derived more advantage from the system than any other country, and on the plea that France had violated the most-favoured-nation clause by utilising the quotas as a means of exchange, Germany was reported to have contemplated a denunciation of the existing commercial treaty with France. The French Government hastened to open negotiations for a revision of the 1927 treaty, so that there is some prospect of a settlement. As showing the situation of the four countries with which France does most business, the trade returns for the first eight months of the year reveal that Germany exported to France goods to the value of 2081 million francs, while the value of exports from France to Germany was 1061 millions. The figures for the United States were respectively 1093 million francs and 351 millions; Great Britain, 1513 millions and 1059 millions; and the Belgian-Luxemburg Union, 1340 million francs and 1411 millions. All the figures for this year have fallen heavily from those for 1932. The situation has become so serious that the plans to recover trade now being initiated by the French Government may be expected to hasten a resumption of negotiations with Great Britain.

Engineering Degrees.

The protest by the Fédération des Associations, Sociétés et Syndicats Français d'Ingénieurs against the Bill now before the Senate for the creation of a State engineering degree was followed by a correspondence, some of which appeared in translation in these columns. Monsieur Couturaud, one of the writers of those letters, has returned to the charge, and deals with the difficulties that have arisen out of the change over from one epoch of industrial activity to another, when the system of rationalisation created a new class of technicians who have swollen the ranks, and, it is affirmed, lowered the status of the profession. Ten years ago the Société des Ingénieurs Civils rejected proposals then made for the protection of engineers because the profession had been honoured by distinguished men who did not possess degrees. Manufacturers themselves had no settled ideas on the matter. Nevertheless, the idea of forming a corporative body of engineers was gaining ground when the Fédération des Associations, Sociétés et Syndicat Français d'Ingénieurs was constituted. The Federation should then have taken in hand the work of organising the profession and granting diplomas. As matters now are, Monsieur Couturaud affirms that the Bill before the Senate will favour an inflation of the engineering profession instead of a deflation. This must, he says, be avoided by taking measures to ensure that degrees will only be granted by schools into which candidates enter by examination; that the Conservatoire des Arts et Métiers will limit the number of diplomas to be granted each year, and that for the State degrees political interference shall not be allowed to influence the examining commission in any shape or form.

Steam and Oil Engine Traction.

During the past summer the State Railways ran a service of Bugatti rail motor coaches between the Paris Gare St. Lazare and Deauville, a distance of 137½ miles, in just under two hours. Last month the motor coaches were replaced by a transformed "Pacific" locomotive, similar to that running on the Paris–Orleans Railway, with Dabeg poppet valves. It hauled four coaches and a van, representing a load of 238 tons. Except for compulsory speed reductions and a slowing down on gradients, the train maintained the maximum permissible speed of 120 kiloms. (74½ miles) an hour, and with an average of 68·68 miles for the full distance, it accomplished the journey in about the same time as the rail motor coach.

The Steel Cartel.

At a meeting of the International Steel Union in Paris last week, the effect of the dollar and sterling fluctuations on the export trade was discussed, particularly with reference to the activity of United States steel producers in South America. The attitude of the Union in face of these currency fluctuations is uncertain. It is felt that any definite action will be paralysed until there is some stabilisation, when it is hoped that British steel makers may be induced to co-operate with Continental producers. Representatives from Austria, Hungary, and Czechoslovakia were present at the meeting with the idea of keeping in line with the Union. It is found difficult to adhere strictly to the method of applying quotas, and while Belgian and German steel makers have kept well within the quantities allotted to them for export the French have fully availed themselves of the liberty allowed to members to accept orders at low prices under certain competitive conditions.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office, Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

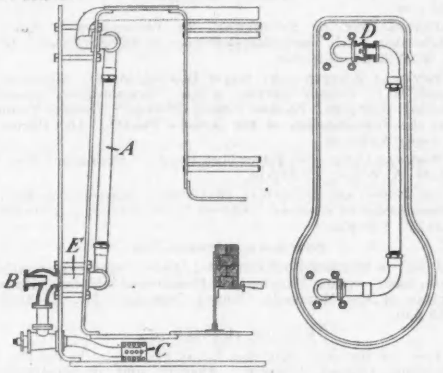
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

STEAM GENERATORS.

397,734. January 30th, 1933.—Circulators for Scotch Boilers, T. C. Nesbitt, 11, Milton-road, West Hartlepool.

In order to equalise the temperature at the top and the bottom of the boiler and thus minimise expansion stresses the inventor arranges a pipe A inside the combustion chamber and introduces the feed water through it. The feed is connected at B and produces an injector action. The inlet to the injector is connected with a strum C in the bottom of the boiler and a non-return valve is provided at D. Where the feed pipe passes through the back plate, at E, it may either be expanded in place or threaded through a larger tube.—*August 31st*, 1933.

Nº397,734

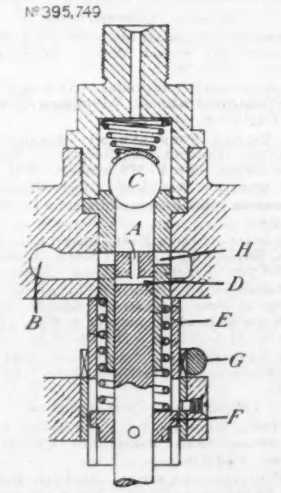


INTERNAL COMBUSTION ENGINES.

395,749. January 21st, 1932.—Fuel Injection Pumps, A. A. Sydney, 36, Chipstead-avenue, Thornton Heath, Surrey.

The working chamber A of this fuel pump is supplied with the oil inlet B and discharges through the loaded ball valve C. The plunger is drilled axially and transversely, as shown at D. The plunger is surrounded by the sleeve E, with which it is connected by the lugs F. The sleeve can be rotated by the rack and pinion G. The rack is connected with the governor, which, by bringing the ports D more or less into alignment with the ports H, bypasses some of the fuel according to the load on the engine.—*July 21st*, 1933.

Nº395,749

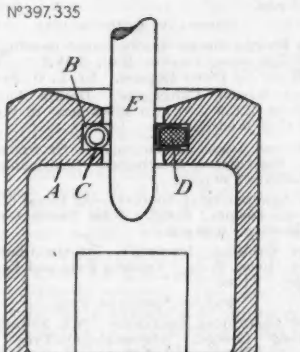


SWITCHGEAR.

397,335. November 1st, 1932.—Liquid-break Electric Switches, International General Electric Company, Incorporated, of 120, Broadway, New York, U.S.A.

In accordance with this invention the aperture in the explosion chamber of a liquid-break switch through which the movable contact rod is adapted to pass is provided with a resilient annular packing similar in action to a stuffing-box in order to prevent the escape of liquid. The wall A of the aperture has a groove B for the reception of a metallic annular helical spring ring C, or, as shown on the right-hand section, a rubber annulus D sheathed with metal, so divided that it does not affect the elasticity of the rubber annulus. The helical spring ring C or the rubber annulus D closely surrounds the contact E. A certain amount of play is, however, provided in the groove B to allow for a lack of alignment of the contact rod.—*August 24th*, 1933.

Nº397,335

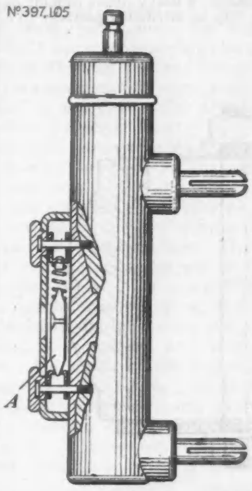


ELECTRICAL APPLIANCES.

397,105. November 12th, 1931.—Electric Cut-outs, Francis Thomas, of 33, St. Stephen's House, Westminster, S.W.1.

According to this invention, in combination with electric mercurial cut-outs, which by reason of their totally enclosed structure give no indication externally on breaking circuit, a neon or other luminous gas discharge tube A is provided, which serves both as an indicating device to show at a glance the continuous or the interrupted condition of the cut-out and as a surge-absorbing device. In a mercurial cut-out there is a tendency for the maintenance of a mercury arc which, for the proper functioning of the cut-out, it is essential to avoid, and it has been found that the provision of a gas discharge tube achieves this result by forming a by-pass so that a current surge through the cut-out itself and the maintenance of a mercury arc are eliminated. It will be seen, therefore, that the provision of a gas discharge tube in combination with a mercurial cut-out has, in addition to its indicating property, a function which is non-existent in the case of such a gas discharge tube in association with a cut-out of the fusible type. While, for the purpose of the invention, any suitable form of gas discharge tube may be used, it is preferred to employ a tube with external electrodes. Each electrode is therefore formed by a metallic coating on the tube, the coatings being separated by a space which is comparatively narrow, for example, in the neighbourhood of one-sixteenth of an inch. The separating space may be enlarged locally to form a window for the purpose of rendering the glow more distinct.—*August 14th*, 1933.

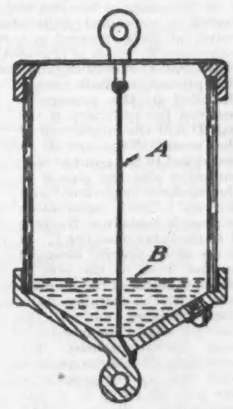
Nº397,105



397,234. March 29th, 1932.—Electric Fusible Cut-outs, William Herbert Turner, of the Grove, Meanwood, Leeds; and William Herbert Isherwood, of 4, Caythorpe-road, Leeds.

The fusible cut-out described in this specification is particularly suitable for the protection of lines and apparatus operating at extra high pressure. The melting of the fuse wire A, whether due to overload or to breakdown, results in the formation of an arc between the two electrodes and through the liquid which is thus vaporised very rapidly and so fills the closed chamber with vapour, which in a very short period reaches a high pressure and causes the vessel B to burst or to give rise to failure of the joints. This allows sudden and almost unhindered expansion and cooling of the vapour surrounding the arc to occur. De-ionisation of the electric field between the electrodes is so rapid that re-establishment of the arc after extinction at zero point of the current curve is prevented.—*August 24th*, 1933.

Nº397,234

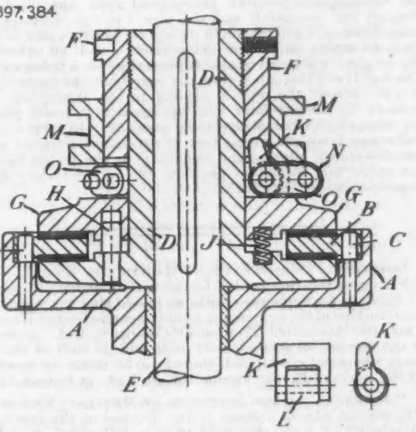


TRANSMISSION OF POWER.

397,384. February 10th, 1933.—Friction Clutches, A. Anderton, of W. R. Anderton and Co., Railway Ironworks, Castleton, Rochdale.

This invention relates to friction clutches of the plate type, in which one or more friction plates secured to one member of the clutch are gripped between plates secured to the other member. A is the outer portion free to revolve on the shaft or keyed to the driving shaft when used as clutch coupling. B is the friction plate fitted with fibre facings, and is a sliding fit in the outer portion A and secured to it radially by pins C. The inner portion D is keyed to the shaft E and is provided with a flange at one end, forming a friction plate, the other end being screwed to receive a collared adjustable bush F. G is a sliding

Nº397,384

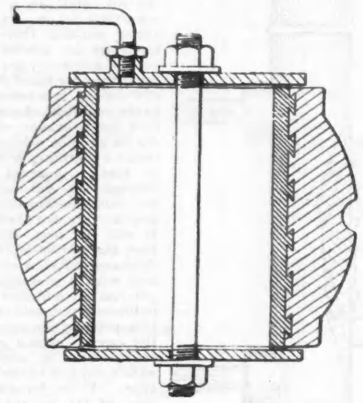


friction plate mounted on the inner portion D and is secured by pins H so as to allow axial movement only. Springs J may be fitted between the friction plates. A number of toggle levers K are fitted between the plate G and the bush F radially arranged round the inner portion D; each of these toggle levers is provided with a jaw at one end to receive the roller L; the opposite end is arranged to pivot in the end face of the collared bush F. M is a sliding sleeve mounted on the collared bush F provided with lugs N and is connected to the toggle levers K by levers O fitted on each side of the lugs and toggle levers. To operate the clutch, the sliding sleeve M is moved towards the friction plates, which alters the inclination of levers O, causing the jawed ends of the toggle levers K to be forced inwards towards the shaft, and the rollers to press against the friction plate G, giving the desired grip.—*August 24th*, 1933.

395,890. March 3rd, 1932.—Bearing Brasses, *P. W. Gray. The Sperry Gyroscope Company, Ltd., Great West-road, Brentford, Middlesex.*

It is suggested that the vibration of heavy rotors running at high speeds on vertical shafts may be attributed partially to a lack of cohesion between the white metal of the bearing and its carcase. The inventors propose to overcome this trouble by expanding the white metal, after it has been cast in place, by hydraulic pressure. The illustration needs no comment.—*July 27th*, 1933.

No 395,890

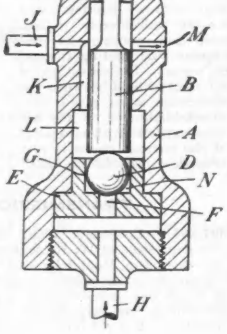


MISCELLANEOUS.

397,439. May 5th, 1933.—Fluid Pressure Regulators, Schweizerische, Lokomotiv und Maschinenfabrik, Winterthur, Switzerland.

This invention relates to an auxiliary control valve for pressure regulators in which the control valve actuates a regulator valve as soon as a predetermined maximum pressure and predetermined minimum pressure are attained. In the drawing A is the casing or housing and B the control piston, which is loaded by a weight C adjustable in any desired manner. The valve ball D is arranged in a recess N of the interchangeable valve seat E, which is provided with a bore F. The diameter of the ball D is only slightly less than that of the recess N, so that pressure medium (air) is throttled in the passage G between the periphery of the ball D and the lateral wall of the recess. The pipe H is connected to the point of consumption and the pipe J to the regulator or governor (not shown). The equalisation channel K leads from the pipe J to the lower chamber L. M is the outlet opening arranged at the level of the pipe J, which establishes communication with a chamber at a lower pressure, and in the example shown communicates with the atmosphere. The operation of the control is such that on the pressure in the pipe H rising to a predetermined degree which corresponds to the load C on the control piston B the ball D, pressed by the latter against its seat, and therefore the piston B will be raised. The throttling passage G ensures that the consumption pressure acting on the whole surface of the lower half of the ball will rapidly raise the piston to its highest position. The connecting pipe M will be now closed by the piston B, and the consumption pressure transmitted from the chamber L through the channel K and the pipe J to the regulator. The control piston B will remain in its highest position only until the pressure acting on it from below falls to such an extent that the weight C will again be able to press the piston B downwardly. The ball D will thereupon close the bore F and the control piston B will uncover the pipe M leading to the atmosphere. The pressure in the regulator will fall again to a lower pressure, for example, to the atmospheric pressure. By replacing the valve seat E by one with a bore of a different diameter and by simultaneously altering the weights C or the piston load, the maximum and minimum pressure can be set to any desired degree.—*August 24th*, 1933.

No 397,439



Correction—Brooke-A.E.C. Marine Oil Engine.—When referring to the Brooke-A.E.C. marine oil engine, on page 265 of our issue for September 15th, we stated that the whole of the construction of the new engine would be carried out at Lowestoft. This, the Associated Equipment Company, Ltd., informs us, is not correct, as all the power units will be built at that company's Southall works, and altered to fit them for marine use at the works of Brooke Marine Motors, Ltd., at Lowestoft.

"Journal" of the Institute of Metals: Volume L.—The second annual volume of the *Journal* of the Institute of Metals, which is devoted entirely to metallurgical abstracts, as distinct from original papers, has just appeared. It is entitled "Metallurgical Abstracts and Index," and contains 962 pages, of which the index covers 177 pages, and has 20,000 entries. The price with two volumes of "Proceedings" is £4. It is claimed to contain concise summaries of everything of a metallurgical character that has recently appeared in the world's technical literature.

Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the TIME *and* PLACE *at which the meeting is to be held should be clearly stated.*

To-day.

Inst. of Chemical Engineers.—In Rooms of Chemical Soc., Burlington House, W.1. "The Sedimentation of Fine Particles in Liquids: A Survey of Theory and Practice," Mr. R. F. Stewart and Dr. E. J. Roberts. 6 p.m.

Institution of Sanitary Engineers.—Caxton House (Hill's Restaurant), Tothill-street, Westminster, S.W.1. Opening sessional meeting. Reception, 7.30 p.m.; music and dancing, 8 p.m. until 11.30 p.m.

Inst. of Production Engineers: London Section.—At Council Room, Soc. of Motor Manufacturers and Traders, 83, Pall Mall, S.W.1. "Jig and Tool Design," Mr. E. J. H. Jones. 7.30 p.m.

Junior Inst. of Engineers.—39, Victoria-street, S.W.1. "Education with Particular Reference to the Engineer," Mr. K. W. Willans. 7.30 p.m.

Physical Society.—At Royal Institution, 21, Albemarle-street, W.1. Council meeting, 4 p.m.; extraordinary general meeting, 5.30 p.m. Thomas Young Oration, "Thomas Young and the Simplification of the Artist's Palette," Dr. Herbert E. Ives. 5.45 p.m.

Railway Club.—57, Fetter-lane, E.C.4. "Permanent Way," Mr. W. A. Willox. 7.30 p.m.

Sir John Cass Technical Institute.—Inaugural meeting. Presentations to students. Address by Sir Robert A. Johnson, K.B.E. 8.15 p.m.

Saturday, October 7th.

Inst. of British Foundrymen: Lancashire.—Engineers' Club, Albert-square, Manchester. Presidential address, "Manufacture of the Mammoth Cunard Castings," Mr. F. Swift. 3.45 p.m.

Monday, October 9th.

Inst. of Metals: Scottish Local Section.—At the Royal Technical College, Glasgow. Display and demonstration, arranged by Professor Robert Hay, B.Sc., Ph.D. (Chairman).

Inst. of Production Engineers.—In the College of Technology, Manchester. "The Growth of the Big Industrial Corporation," Mr. W. L. Hichens. 7.30 p.m.

Iron and Steel Inst.—Royal Metal Exchange, Swansea. "Fifth Report of the Committee on Heterogeneity of Steel Ingots," "Effect of Tin as an Impurity in Mild Steel," Mr. J. H. Andrew and Mr. J. B. Pfeile; "Factors Leading to Greater Production from a Steel Furnace," Mr. A. Robinson. 7 p.m.

Soc. of Chemical Industry.—In the Chemical Society's Rooms, Burlington House, W.1. "Tung Oil: Chemical Studies and Specifications," Dr. L. A. Jordan, and "Application of Fumigants to Warehouses," Dr. A. B. Page. 8 p.m.

Tuesday, October 10th.

Illuminating Engineering Soc.—At the Lighting Service Bureau, 2, Savoy-hill, Strand, W.C.2. Presidential address, Mr. C. W. Sully. 6.30 p.m.

Inst. of Automobile Engineers.—At King's Head Hotel, Coventry. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7.30 p.m.

Inst. of British Foundrymen: Burnley Section.—Municipal College, Ormerod-road, Burnley. "Foundry Essentials and Incidentals," Mr. F. Whitehouse. 7.15 p.m.

Inst. of Metals: Swansea Local Section.—At the Y.M.C.A., Swansea. Chairman's address, by Dr. A. G. Ramsay, B.Sc. 6.15 p.m.

Inst. of Metals: North-East Coast Local Section.—In the Electrical Engineering Lecture Theatre, Armstrong College, Newcastle-on-Tyne. Exhibition of films. 7.30 p.m.

Inst. of Petroleum Technologists.—At the House of the Royal Society of Arts, John-street, Adelphi, W.C.2. "The Modern High-speed Diesel Engine and its Place in Road Transport," Major W. H. Goddard, A.M.I. Mech. E. 5.30 p.m.

Sheffield Metallurgical Association.—198, West-street, Sheffield. "Properties of Austenitic Steels," Dr. L. B. Pfeil. 7.30 p.m.

Wednesday, October 11th.

Inst. of Civil Engineers: Manchester and District Assoc.—36, George-street, Manchester. Chairman's address, Mr. A. C. Dean. 6.45 p.m.

Inst. of Engineers-in-Charge.—St. Bride Institute, Bride-lane, E.C.4. Presidential address, "The E.I.C. and his Need for Administrative Ability," Lieut.-Col. J. D. K. Restler, O.B.E. 7.30 p.m.

Inst. of Fuel.—In the Lecture Hall of the Geological Soc. of London, Burlington House, Piccadilly, W.1. The Melchett Lecture, "The Place of Oil in the World of Fuel," Sir John Cadman. 5.30 p.m.

Newcomen Soc. for the Study of the History of Engineering and Technology.—In the Hall of the Chartered Inst. of Patent Agents, Staple Inn-buildings, London, W.C.1. Mr. H. W. Dickinson, M.I. Mech. E., will deliver his presidential address at 5.30 p.m.

Television Soc.—At University College, Gower-street, W.C.1. "Television at the 1933 Berlin Radio Exhibition," Mr. E. H. Traub. 7 p.m.

Thursday, October 12th.

Diesel Engine Users Assoc.—Joint meeting with Inst. of Chemical Engineers, Caxton Hall, S.W.1. "Treatment of Cooling Water for Diesel Engines," Mr. L. O. Newton. 3 p.m.

Inst. of Marine Engineers: Junior Section.—85–88, The Minories, E.C.3., "'Two Milestones' in Workshop Practice," Mr. G. J. Wells. 7 p.m.

Manchester Assoc. of Engineers: Students' Section.—Y.M.C.A., Peter-street, Manchester. Chairman's address, Mr. Frank Walker. 7.30 p.m.

Royal Aeronautical Society.—At Royal Society of Arts, John-street, Adelphi, W.C.2. "Air Traffic Control," Major R. H. S. Mealing. 6.30 p.m.

Soc. of Chemical Industry.—At the Chemical Society, Burlington House, W.1. "Canning Fruit and Vegetables," Mr. G. Cadbury. 8 p.m.

Friday, October 13th.

Inst. of Electrical Engineers: N.E. Students' Section.—Armstrong College, Newcastle-upon-Tyne. Chairman's address, "The Rating and Performance of Circuit Breakers," Mr. R. W. L. Harris. 7.15 p.m.

Inst. of Engineers and Shipbuilders in Scotland.—Grosvenor Restaurant, Glasgow. "James Watt" dinner.

Inst. of Metals: Sheffield Local Section.—In the Non-ferrous Section of the Applied Science Department of the University, St. George's-square, Sheffield. "Centrifugal Casting of Non-ferrous Alloys," Mr. F. W. Rowe, B.Sc. 7.30 p.m.

Junior Inst. of Engineers.—At 39, Victoria-street, S.W.1. "The Influence of Harmonics in Transformer Circuits," Mr. Ernest Ambrose, M.I.E.E. 7.30 p.m.

Manchester Assoc. of Engineers.—Engineers' Club, Manchester. Presentation of Medals. Presidential address, Dr. T. B. Morley. Smoking concert. 7.15 p.m.

Saturday, October 14th.

Inst. of Marine Engineers: Junior Section.—85–88, The Minories, E.C.3. Social and dance. 7.30 to 11.15 p.m.

Monday, October 16th.

Bradford Engineering Soc.—Joint meeting with the Technical College, at the Technical College, Bradford. "Degreasing of Metals," Mr. H. O. Brown. 7.30 p.m.

Tuesday, October 17th.

Inst. of Marine Engineers.—85–88, The Minories, E.C.3. "Oil from Coal," Dr. W. R. Ormandy and Dr. J. Burns. 6 p.m.

Sheffield Metallurgical Soc.—198, West-street, Sheffield. "Exhaust Valve Failures," Mr. C. C. Hodgson. 7.30 p.m.

Wednesday, October 18th.

Inst. of Fuel.—In the Lecture Hall of the Geological Soc. of London, Burlington House, Piccadilly, W.1. Presidential address by Sir Wm. J. Larke. 11.30 a.m.

Inst. of Fuel.—At Geological Society's Rooms, Burlington House, W.1. "Recent Developments in Coking Practice," Dr.-Ing. H. Koppers. 2.30 p.m.

Inst. of Fuel.—Connaught Rooms, Great Queen-street, W.C.2. Annual dinner and dance. Presentation of the Melchett Medal to Sir John Cadman. 6.45 for 7.15 p.m.

Friday, October 20th.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. Informal meeting; election of Sub-committee. 7 p.m.

Inst. of Sanitary Engineers.—At Caxton Hall, Westminster, S.W.1. "Aggregates for Concrete Work," Dr. Bernard H. Knight. 6 p.m.

Junior Inst. of Engineers.—At 39, Victoria-street, S.W.1. "Air Lift Pumps," Mr. A. C. Judd (member). 7.30 p.m.

North-East Coast Institution of Engineers and Shipbuilders.—Bolbec Hall, Newcastle-upon-Tyne. Annual general meeting. Address by the President, Mr. R. J. Walker; cinematograph film, "Mechanism of Ships' Wake," Professor T. B. Abell.

Saturday, October 21st.

Inst. of Electrical Engineers: N.E. Students' Section.—Visit to Messrs. A. Reyrolle and Co.'s short-circuit test plant, Hebburn. 2.30 p.m.

Inst. of Mechanical Engineers: Graduates.—Visit to the de Havilland Aircraft Company, Stag-lane Aerodrome, Edgware.

Tuesday, October 24th.

Inst. of Automobile Engineers.—At Hotel Victoria, Wolverhampton. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7.30 p.m.

Inst. of Engineers and Shipbuilders in Scotland.—39, Elmbank-crescent, Glasgow, C.2. "Flame Cutting of Steel for Welded Joints," Mr. E. J. Clarke. 7.30 p.m.

Sheffield Metallurgical Soc.—198, West-street, Sheffield. "Our Knowledge of the Conditions in the Blast-furnace," Mr. R. C. Tucker. 7.30 p.m.

Wednesday, October 25th.

Inst. of Mechanical Engineers: Yorkshire.—Grand Hotel, Sheffield. "Fatigue and Corrosion Fatigue, with Special Reference to Service Breakages," Prof. Frederic Bacon. 7.30 p.m.

Thursday, October 26th.

Glasgow University Engineering Soc.—At James Watt Engineering Laboratories, University. Presidential address by Mr. H. A. Reincke. 7.30 p.m.

Inst. of Electrical Engineers.—Savoy-place, W.C.2. Presidential address, Mr. P. V. Hunter. 6 p.m.

Inst. of Mechanical Engineers.—At Dorchester Hotel, Park-lane, W.1. Annual dinner, 6.45 for 7.15 p.m.

Inst. of Mechanical Engineers: Yorkshire.—Queen's Hotel, Leeds. "Fatigue and Corrosion Fatigue, with Special Reference to Service Breakages," Prof. Frederic Bacon. 7.30 p.m.

Midland Metallurgical Societies.—In the James Watt Memorial Inst., Gt. Charles-street, Birmingham. Discussion, "The Production of Sound Cast Iron Castings." 7 p.m.

Friday, October 27th.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. General meeting. Presidential address, Mr. Alan E. L. Chorlton. 6 p.m.

Junior Inst. of Engineers.—At 39, Victoria-street, S.W.1. "The Electrolytic Theory of Corrosion," Mr. H. E. Yerbury, M. Inst. C.E., M.I. Mech. E., M.I.E.E. 7.30 p.m.

Saturday, October 28th.

Stephenson Locomotive Society.—Visit to Stratford, L.N.E. Railway Running Sheds. 2.30 p.m.

Monday, October 30th.

Bradford Engineering Soc.—Technical College, Bradford. "Salvage Work on the Ex-German Fleet at Scapa Flow," Mr. E. F. Cox. 7.30 p.m.

Inst. of Automobile Engineers.—At 39, Elmbank-crescent, Glasgow. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7.30 p.m.

Inst. of Mechanical Engineers: Graduates.—Storey's-gate, S.W.1. "Stainless Steels," Mr. F. J. Murdoch. 6.45 p.m.

Tuesday, October 31st.

Inst. of Transport.—15, Savoy-street, W.C.2. Discussion, "The Duties of a Modern Transport Manager," Mr. M. F. Barnard.

LAUNCHES AND TRIAL TRIPS.

Steel Barges (three); built by Richard Dunston, Ltd., to the order of London owners; launch, September 26th.

Pass of Balmaha, oil tanker; built by Blythswood Shipbuilding Company, Ltd., to the order of Bulk Oil Steamship Company, Ltd.; dimensions, 200ft. by 30ft. 6in.; to carry oil in bulk. Engines, triple-expansion, 15in. by 25½in. by 41in. by 30in. stroke, pressure 190 lb. per square inch; constructed by David Rowan and Co., Ltd.; trial trip, September 27th.

University College Dinner.—A dinner to celebrate the fiftieth anniversary of the founding of the Engineering Society of University College, London, by Sir Alexander Kennedy, will be held in the College refectory on Thursday evening, November 16th, with Mr. Roger T. Smith in the chair. Tickets, 8s. 6d. each, may be obtained from Professor W. C. Clinton at the College.

A Seven-Day Journal

◆

Testimonial to Sir Henry Lyons.

To mark the retirement of Sir Henry Lyons, F.R.S., from the position of Director of the Science Museum, South Kensington, a presentation was made to him in the Science Museum on Wednesday morning, October 11th. Sir Richard Glazebrook, F.R.S., presided at the gathering in the Lecture Theatre, and among those present were Lord Irwin (President of the Board of Education), Sir Henry Pelham (Secretary to the Board of Education), Lord Rayleigh, F.R.S., Lady Lyons, and a large number of friends and colleagues of Sir Henry Lyons. Before the presentation and reading of an address to Sir Henry, signed by all the members of the Advisory Council of the Museum—who also were responsible for the gift of a handsome mahogany writing table—Sir Richard spoke of the manner in which the Science Museum has developed under the direction of Sir Henry Lyons, and at the same time he read several letters from prominent men, expressing appreciation of his work and suggesting, as a mark of the work of Sir Henry, that a new central block should be started at an early date. The address presented to Sir Henry Lyons expressed the regret of all the members of the Advisory Council of the Science Museum at his retirement, and their great appreciation and admiration of the work he had done. It recalled that when, in 1920, Sir Henry was appointed, the Museum was a small institution known only to a few. The eastern block, planned in pre-war days by Sir Hugh Bell's Committee, was incomplete. The collections, scattered throughout various unsuitable buildings, were without order and arrangement. By his tact, energy, and ability, however, Sir Henry had made the Museum what it now is and was known to be—a treasure house of past achievements and an inspiring guide to future progress. One single fact sufficed to indicate the magnitude and success of his work: the number of visitors had increased from about 400,000 in 1921 to nearly 1¼ millions in 1932. Lord Irwin made the presentation, and Sir Henry Lyons, expressing his thanks for what had been said of his services and for the gift, at the same time spoke of his gratitude to the Board of Education for encouraging him to develop the idea of a modern technical museum. At present there were only two in existence—the Science Museum, South Kensington, and one in Germany—but twelve others were being developed in other countries. The wisdom of that work was seen in the increasing number of persons visiting the Science Museum.

Industrial Uses of Gas.

In the course of a paper read at the Scottish Conference of the British Commercial Gas Association, which took place at Dunfermline last week, Mr. J. W. M'Lusky, the general manager of the Glasgow Corporation Gas Department, dealt with the development of the industrial field. There was no doubt, he said, that the 18,000,000 tons of coal purchased annually by the gas undertakings of the British Isles could be very largely augmented if the advantages of gaseous fuel were brought home to industrialists. In addition to the basic industries, there were many special industries in which gas was being widely used. In the Glasgow area recent developments in the industrial field had, for instance, been more pronounced in the baking trade than in the engineering and allied industries. With regard to conversions from oil to gas, the general attitude was very favourable towards gas, but with the proposed oil-from-coal schemes many manufacturers using oil were prepared to await future developments. A few instances in which gas had been used, and was being formally considered in preference to oil, included, he said, oven furnaces for spring-making and heat treatment in a railway engineering works; gas-fired boilers for varnish manufacture, and furnaces for melting brass and type metal.

Two Important Motor Ship Launches.

Two important launches of motor ships have recently taken place, one on the Tyne and the other in Belfast. The Tyne-built ship is the "Port Chalmers," which has been constructed by Swan, Hunter and Wigham Richardson, Ltd., at the firm's Wallsend yard, for the service of the Commonwealth and Dominion Line, Ltd., of London. The ship, which was launched on Tuesday, October 3rd, has a length of 486ft. 6in., a beam of 65ft. 3in., and a measurement of about 8800 gross tons. Here deadweight carrying capacity is close upon 11,500 tons. A feature of her hull construction has been a free use of welding instead of riveting in many parts of the structure. Although she will carry about twelve passengers, the new ship is mainly designed for the carriage of perishable goods, such as meat, fruit, and dairy products, and no less than 46,500 cubic feet of insulated space is provided in her holds and 'tween deck spaces. The refrigerating equipment has been designed by J. and E. Hall, Ltd., of Dartford, and includes special refrigerating and ventilation arrangements. The propelling machinery consists of a twin-screw arrangement of Barclay Curle-Doxford opposed-piston engines, designed to give the ship a speed of about 15½ knots when running at 96 r.p.m. The auxiliary machinery equipment is electrically operated for the most part. The Belfast launch, which took place on Monday last, October 9th, from the yard of Workman Clark (1928), Ltd., was that of the motor liner "Isipingo," one of three now being built for the mail and cargo services of Andrew Weir and Co., Ltd., of London, between Indian and South African ports. The new ship has an overall length of 425ft., a breadth moulded of 57ft., and a depth of 37ft. She will carry a full complement of first, second, and third-class passengers, as well as general and refrigerated cargoes. The propelling machinery, constructed in the builders' shop, consists of two sets of Workman Clark-Sulzer engines, designed to give the vessel a speed of 15 knots.

Statistics in Industry.

The Council of the Royal Statistical Society has decided to form a section for the purpose of promoting the application of methods of statistical analysis to problems in industry and agriculture. In the last decade or so there have been considerable developments in the application of modern statistical methods to technical problems met with in industry and agriculture. In the opinion of the Council the time is now ripe for the formal provision of facilities which will give a common platform for discussion to those who have problems to solve requiring the use of these methods. There are, on the one hand, special research problems involving careful planning and experiment, such as occur from time to time at an agricultural research institution, or in the research department of a large industrial firm. There are also many problems that arise in the course of routine production and exchange; problems of sampling and testing; questions as to whether measurements taken are used to best advantage; how far they are adequate for the purpose intended, and to what extent some of them may even be redundant. The facilities provided by the section will be two-fold—(1) the holding of regular meetings, and (2) the publication of a Supplement to the *Journal* of the Royal Statistical Society which will be devoted entirely to the study of this aspect of statistical science. The first meeting will be held on Thursday evening, November 23rd next, at the Hall of the Royal Society of Arts, John-street, Adelphi, at 5.30 p.m.

The Metropolitan Water Board.

At a meeting of the Metropolitan Water Board, held on Friday last, October 6th, Lieut.-Colonel J. R. Davidson, chief engineer to the Liverpool Corporation waterworks, who, on attaining the age of sixty on May 30th, 1934, will retire on pension, was appointed chief engineer to the Board at a salary of £5000. It was pointed out by the General Purposes Committee that important matters requiring early consideration, with regard to the adequacy of the Board's works to meet future requirements, were now pending. These included questions of additional storage, improved means of distribution, intercommunication, and the modernisation of the pumping machinery. While the Committee had every confidence in the deputy chief engineer, recently appointed, it considered it desirable to secure for a limited period the services of a water engineer of the highest distinction and experience. Mr. F. G. Howard, the Chairman of the Committee, said that while it was the policy of the Board to promote from within its own staff, their own engineers lacked the long and varied experience which the position demanded. The work in prospect would involve an expenditure of possibly £4,000,000, and if the Board was to engage consultants the fees payable would be £100,000. There was some opposition to the proposal of the Committee, but Lieut.-Colonel Davidson was appointed by 31 votes to 5. At the same meeting it was reported that Sir Alexander Houston, Director of Water Examinations, had tendered to the Board his resignation as from the end of the present year. In accepting the resignation the Board placed on record its high appreciation of Sir Alexander Houston's services during the past twenty-eight years.

A Clydebank Naval Order.

The Admiralty announces that the contract for building the convoy sloop H.M.S. "Bittern," has been placed with John Brown and Co., Ltd., of Clydebank. The new vessel, we understand, will have a normal displacement of about 1500 tons, and will provide employment for hundreds of men over a period of about eighteen months. The new order brings the number of naval vessels now under construction at Clydebank to five. In February last the firm received orders for two "Fearless" class destroyers, while work is also well advanced on the two mine-sweeper sloops "Skipjack" and "Halcyon," which were ordered in September, 1932. Six of the eight building berths at Clydebank are now occupied, the largest being taken by the unfinished new Cunarder. The sloop order above mentioned is the only naval vessel of the 1933 programme to be proceeded with this year. The Admiralty 1933 programme includes four cruisers, a flotilla leader, eight destroyers, three submarines, and four sloops, in addition to the one just ordered, besides other small craft. Most of these ships are to be built in private yards, and the contracts will, it is expected, be given out about February or March next year.

Steel Trade Improvement.

In a speech on Tuesday, October 3rd, following his installation as Master of the Cutlers' Company of Hallamshire, Mr. J. C. Walsh referred to the definite improvement in the steel trade which had taken place since the beginning of the year. Sheffield was now producing, he said, a greater tonnage of steel than in pre-war times, and something like 27,000 tons a month more than in the corresponding period of last year. The average monthly output of steel for the whole country over the first eight months of the year was more than 99,000 tons greater than the monthly average for the whole of 1932, and with the addition of several large new furnaces which had been started up in various parts of the country, the output would be substantially increased. Mr. Walsh was of the opinion that some share of the improvement must be attributed to the tariffs on imported steels. The newer Sheffield products, such as magnets, razor blades, and stainless steels, had made great strides during the year, and there was a likelihood of further developments in these special lines. He spoke of the larger passenger and goods returns on the railways, as an evidence of Britain's increasing prosperity, and expressed the hope that the companies would soon resume their normal programmes of renewals, for railway materials were largely supplied by Sheffield manufacturers. Mr. J. C. Walsh is a general manager of the United Steel Companies, Ltd., and he succeeds Colonel A. N. Lee in the office of Master Cutler.

Improved Unemployment Figures.

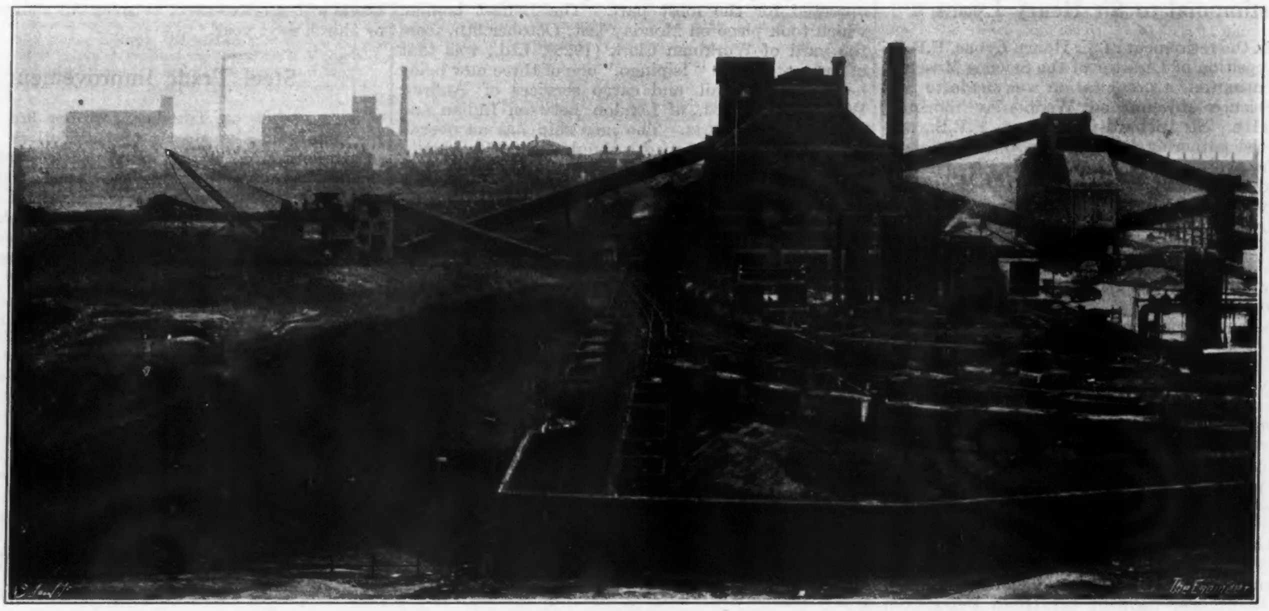
According to a statement issued by the Ministry of Labour early in the week, the figures for September 25th, 1933, show a marked decrease in the number of unemployed persons. There were 74,410 less unemployed than in the preceding month and 521,284 less than a year ago, the present figure having brought down the number of unemployed to 2,336,727. With regard to the employment of insured persons, last month's returns show an increase of 86,000 for the month, or 792,000 more than a year ago, which bring the number of employed up to 9,943,000. It is pointed out that the figures for each month of the present year, with the exception of July, in which there was an increase of 4000, have indicated a steady decrease in the number of unemployed persons, the total being well over half a million less than at the end of January last. Among the industries which show the largest increase in employment during the January–September period, is coal-mining, which now has 46,000 fewer unemployed, mainly in the Midland, Yorkshire and North-Eastern areas. The reduction of unemployment in other industries is indicated by the figures given below:—Iron and steel, 8000; general and electrical engineering, 5000; motor car manufacture, 6000; metal goods manufacture, 8000; pottery, 7000; cotton, 11,700; wool, 5500; hosiery, 2000; jute, 1200; and boot and shoe, nearly 4000. These eleven important industrial groups show together a total decrease of over 104,000 unemployed. The unemployed figures for Germany were also better last month.

Bridge Replacement at Neasden.

A remarkable engineering feat was successfully accomplished at Neasden on Sunday, last, October 8th, when a 60-ton bridge carrying the Cricklewood–Acton branch line of the L.M.S. Railway over Neasden-lane, N.W., was dismantled and replaced by a new structure weighing 160 tons in a single day. The new bridge, which has been provided in order to permit of the working of heavier locomotives over this section of the L.M.S. line, had been erected beforehand on trestling above the roadway. Operations began early on Sunday morning with the arrival of a 36-ton steam crane from the L.M.S. depôt at Kentish Town, N.W., together with a train of wagons and other equipment in charge of expert engineers and some 100 railway and other workmen. The old bridge was rapidly demolished, the girders, flooring, and other parts of the structure being lifted out of position by the steam crane, which loaded the material into rail wagons for removal, while a gang of men with compressed air drills cut up the stone abutment of the old bridge. Shortly after 4 p.m., before the last pieces of the old structure had been removed, work was begun on moving the new bridge into position, this being performed by four men winding on winches, whereby the complete bridge was moved on ball bearings along the trestling into its place. By Sunday night the complete bridge was in position and tracks laid over it in time for the passage of the first train on Monday morning, the work being completed well within scheduled time.

HIGGINSHAW GASWORKS OF THE OLDHAM CORPORATION

MR. F. GREENHALGH, BOROUGH GAS ENGINEER, DESIGNER



Oldham Gasworks.

THE new gasworks of the Oldham Corporation are probably the most modern and elaborately equipped of their kind in the country, for they have not yet been in operation for six months. They have been erected in consequence of the steadily increasing local demand for gas, and on account of the fact that there was only a margin, with the old plant, of 6 per cent. between the maximum daily demand and output. There were, of course, the gasholders to fall back upon in case of emergency. The new works have been constructed to the designs of Mr. F. Greenhalgh, the Borough Gas Engineer, and are illustrated by the accompanying drawings and engravings.

Previous to the alterations the Borough possessed three gasworks: one, known as the Central, equipped with Dempster-Toogood continuous vertical retorts capable of producing 1,000,000 cubic feet of gas a day; another, at Hollinwood, with Glover-West continuous vertical retorts making 3,000,000ft. a day, with a subsidiary water-gas plant of 1,500,000ft.; and the Higginshaw works. It is the latter which have been remodelled. They were originally equipped with horizontal retorts, capable of producing 2,750,000 cubic feet of gas a day, which were about thirty years old.

The Higginshaw site is well in the centre of the district to be supplied and has an area of 33 acres of made ground. It has a connection with the L.M.S. Railway and siding accommodation for 120 wagons. The old buildings, which are indicated by dot and dash lines on the map on page 349, have been entirely demolished and in their place the new gas-making plant housed. The relative sizes of the old and the new plants and how space has been saved by the adoption of modern carbonising plant in the place of the old horizontal retorts will be appreciated. The new plant is capable of producing 4,500,000 cubic feet of gas a day, or nearly twice as much as the old, while it occupies much less space. It is intended to carbonise 234 tons of coal a day.

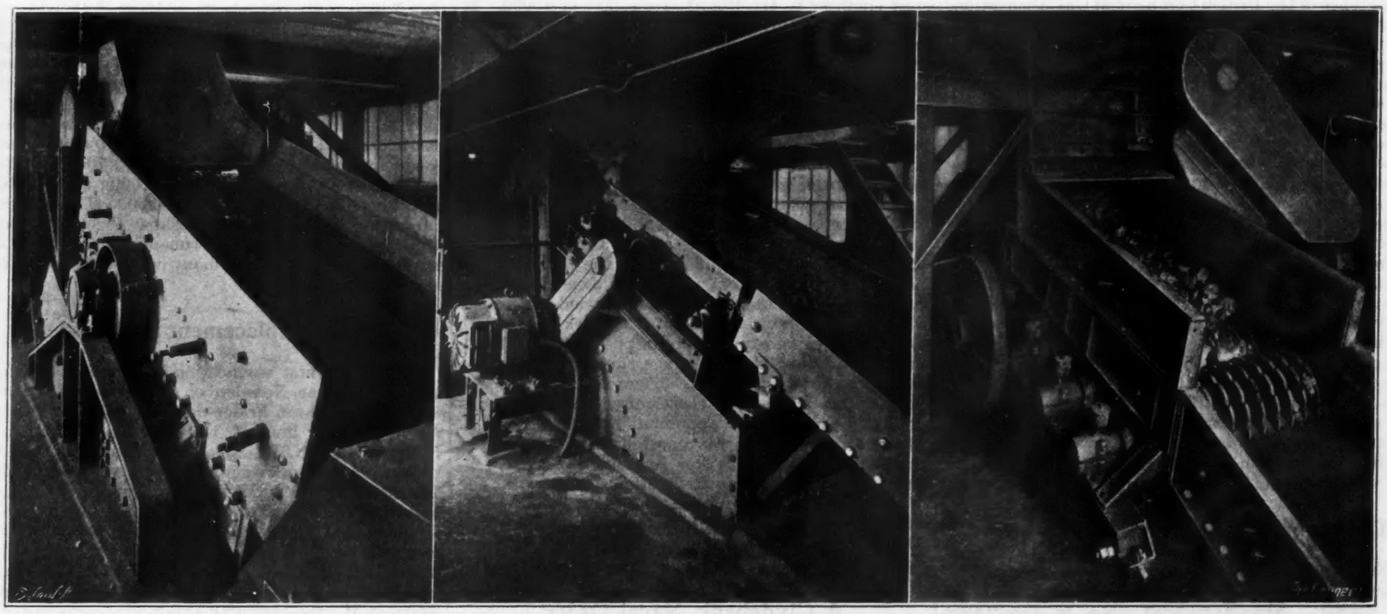
The essential features of the new works comprise an entirely new carbonising plant with vertical retorts, an extensive system of conveyors and cranes for handling the raw coal and coke, a plant for classifying and dispatching the coke, and by-product recovery apparatus, together with all their ancillary services. As will be seen from the plan, the raw coal comes in on one side of the site, is carbonised at the centre, and leaves, as gas and coke, on the opposite side. Incidentally, the "lay-out" has been so arranged that extensions can be conveniently carried out.

The Carbonising Plant.

The carbonising plant, which was supplied by the Woodall-Duckham Vertical Retort and Oven Construction Company (1920), Ltd., of 136, Victoria-street, Westminster, comprises a group of twenty-eight vertical retorts arranged in two rows of fourteen back to back, with the producers necessary for supplying the heating gas on one side of the row and the boilers used for conserving the otherwise waste heat on the other side. The arrangement of the various units is well illustrated by our drawings on page 351. The retorts are about 25ft. high, rectangular in section, 103in. across, and 10in. wide at the top, and taper outwards towards the bottom to allow the free descent of the charge. Between the retorts there are the flues, in which the heating gas is burned, and ultimately goes away as waste gas, whose heat is used for steam raising.

The raw coal is fed into the retorts from overhead hoppers, the supply to which will be described later, through rotary valves into auxiliary hoppers that are virtually upward extensions of the retorts, but are not subject to the coking heat. From them it falls into the retorts where the volatile constituents are dispelled by the heat conducted inwards from the heating flues. The rate of descent of the charge, and consequently the period during which it is subjected to the carbonising effect, is dependent on the rate at which the coke is withdrawn at the bottom of the retort.

The bottom is formed as a curved plate, on which the weight of the charge rests, with a side opening closed by a star wheel having helical vanes. This wheel is rotated at a speed appropriate to the rate at which discharge is required by a reciprocating horizontal bar on which tappets can be fixed at any desired interval. The coke passing the star wheel falls into another hopper which will hold as much coke as is generally made in two hours. The bottom of this hopper is sealed by a valve that is opened

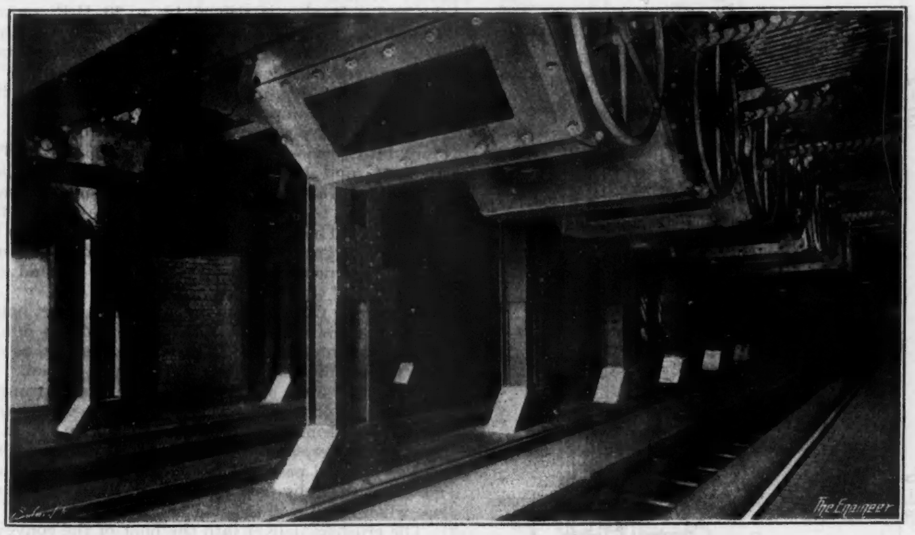


VIBRATING SCREENS AND ROTATING GRIZZLIES IN COKE SCREENING PLANT

Charging Hopper and Floor Levels of Gas Producers

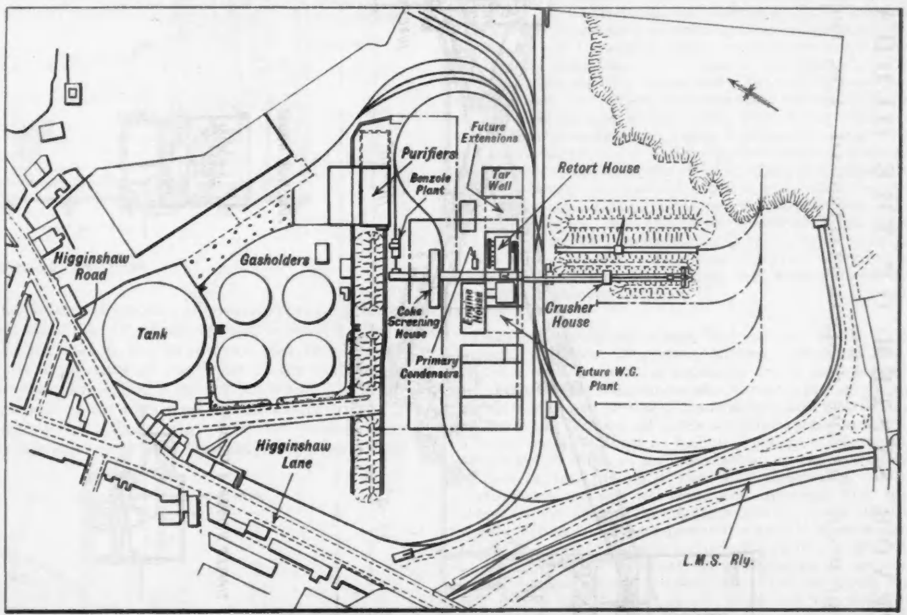
"Aeroplane" Distributor

every two hours for the discharge of the coke. It will thus be seen that the retort is sealed away from the atmosphere and there is a continuous downward flow of the charge, while the gas generated is taken off at the top into a collecting main. Each retort is provided with a mushroom valve in the off-take pipe, so that it may be isolated. Another main is provided on each side of the retort setting in which the gas is sprayed with hot ammoniacal liquor. The liquor is circulated round and round a system which includes wells for the collection of the tar washed out of the gas. The gas and the surplus liquor go on to the by-product recovery plant and the gas ultimately to the town's mains. One of the retorts at the end of the bench is provided with separate connections to a small purifying plant so that it can be used for unfamiliar brands of coal and the best carbonising procedure determined.



Coke Discharge Apparatus Below Main Retorts

The heat necessary for carbonising the coal is provided by gas generated in producers alongside the battery of retorts. There are seven producers in all, and they use a mixture of small coke and breeze from the retorts that is of such a low quality as to be hardly worth selling. The producers are of the stepped grate type and their form is shown in the sectional drawing on p. 351. They all discharge into one main for the distribution of the gas to the heating flues of the retorts, and are so equipped with doors, air and steam injection that they can be adapted to immediate requirements.



"The Engineer"

Map Showing Arrangement of Gasworks Plant

After passing through the heating flues the gases, naturally, have a considerable amount of sensible heat, and this is secured for useful purposes by passing them through either one of two waste heat boilers.

These boilers are arranged on the opposite side of the retorts to the producers, and either one of them is capable of providing nearly all the steam necessary to run the plant. The boilers are of the tubular type, and work under induced draught. The working steam pressure is 160 lb. per square inch, and the steam, except so much as may be necessary to send directly to the retorts and producers, is superheated in the waste gas flues. The feed water for the boilers is preheated by exhaust steam.

The gas made in the retorts first passes through a primary tar extractor of the Holmes cyclone type, and is then cooled in condensers of the tubular type, the "pull" on the retorts being determined by two Arca regulators controlling butterfly valves in the uptakes. It is then forced by exhausters into a secondary single-column condenser, where it is finally cooled to a temperature within 5 per cent. of that of the circulating water. The exhausters, by G. Waller and Son, Ltd., of Stroud, are of the four-bladed type, and are capable of delivering 200,000 cubic feet of gas per hour against a pressure of 50in. at the outlet and minus 6in. at the inlet when running at 60 revolutions per minute. They are driven by 80 H.P. non-condensing engines controlled by hydraulic-steam governors in correct proportion to the make of gas.

From the secondary condenser the gas passes through a Livesey washer and thence into a Holmes double-unit rotary brush washer. The washed gas is taken to some oxide beds, which were put down in connection with the old plant, for the removal of sulphur compounds. Air for the regeneration of the oxide *in situ* is supplied by a Connersville blower driven by the brush washer. The purified gas then goes to a Holmes debenzolising plant which recovers about 1 gallon of benzole for every ton of coal carbonised.

As the new works have to work in parallel with the other two plants, the gas is boosted up in pressure and delivered to the holders there through a 24in. main. There are two rotary four-blade boosters, by G. Waller and Son, Ltd., of Stroud, for this purpose. They are each capable of delivering 250,000 cubic feet of gas per hour against a pressure of 40in. W.G., when running at 60 revolutions per minute, and are driven by horizontal non-condensing engines of 65 I.H.P. Two small rotary Waller compressors supply gas to a high-pressure lighting system.

The other principal product of the works—coke—will be dealt with in connection with the conveyor system, but before going on to that part of the works it may be as well to give a brief account of the power plant.

The Power Plant.

The steam supply from the waste heat boilers is augmented by that from three Lancashire boilers at the back of the engine house, which are fired with coke and breeze. It is delivered from both sets of boilers to a common ring main underneath the engine-room floor at a pressure of 160 lb. per square inch, and the plant has been so laid out that the length of the piping has been reduced to a minimum.

In the engine-house there are besides the boosters already referred to three electric generating sets by Ashworth and Parker, of Bury, with General Electric dynamos. They are each of 125-kW capacity, with a 25 per cent. overload, and are of the enclosed compound type. There is a pass-out from the intermediate receiver from which steam, at a pressure of 30 lb. per square inch, is taken for the service of the retorts and producers, while the low-pressure cylinder exhausts against a back pressure of 5 lb. into a main that provides steam for feed-water heating and general service about the buildings. The dynamos are compound-wound, and generate current at 440 and 220 volts. The exhaust from the booster engines is dealt with in the same way as that from the generating sets. The engine-room, it might be mentioned in passing, is most pleasant as regards its cleanliness and airiness, which is in striking contrast to the atmosphere of most gasworks.

The Conveyors.

Reverting now to the conveyor system which handles all the raw material in the way of incoming coal and the outgoing coke. It was supplied by the Fraser and Chalmers Engineering Works of the General Electric Company, and resolves itself broadly into sections for receiving coal from the railway and putting it either into stock or delivering it directly to the retort-house; with a subsequent system for taking away, grading, and delivering the coke. The lay-out of this plant is well illustrated by the line drawing alongside. It has a capacity for taking coal at the rate of 240 tons per hour from the railway siding on to the storage ground and delivering to the retort house, either from the store or directly from the siding at the rate of 80 tons per hour.

The coal trucks are first weighed on an Avery machine and are then tipped by a Mitchell machine capable of handling 20-ton trucks into an underground hopper. This hopper has two outlets at the bottom, beneath each of which there is a reciprocating feeder, capable of handling coal up to 12in. cube, that discharges on to the rising conveyor marked A on our drawing. This conveyor is of the Robins rubber belt type, 30in. wide, and is 119ft. long between centres. It rises 37ft. 6in., runs at a lineal speed of 375ft. per minute, and is driven by a 20 H.P. motor. At the head of this conveyor, in the junction house, there is a discharge chute having branches for leading the coal either directly to the storage conveyor B, or through crushers to the boot of the elevator C that feeds the retort house. The conveyor B runs over the stock pile on a trestle and is 30in. wide by 173ft. long, and has a slight rise of 9ft. towards the end. It also is driven by a 20 H.P. motor. Straddling this conveyor there is what is described as an "Aeroplane Trimmer," which comprises two short conveyors, each about 15ft. long, that rise at an angle of 18 deg. on either side and discharge the coal on to the dump.

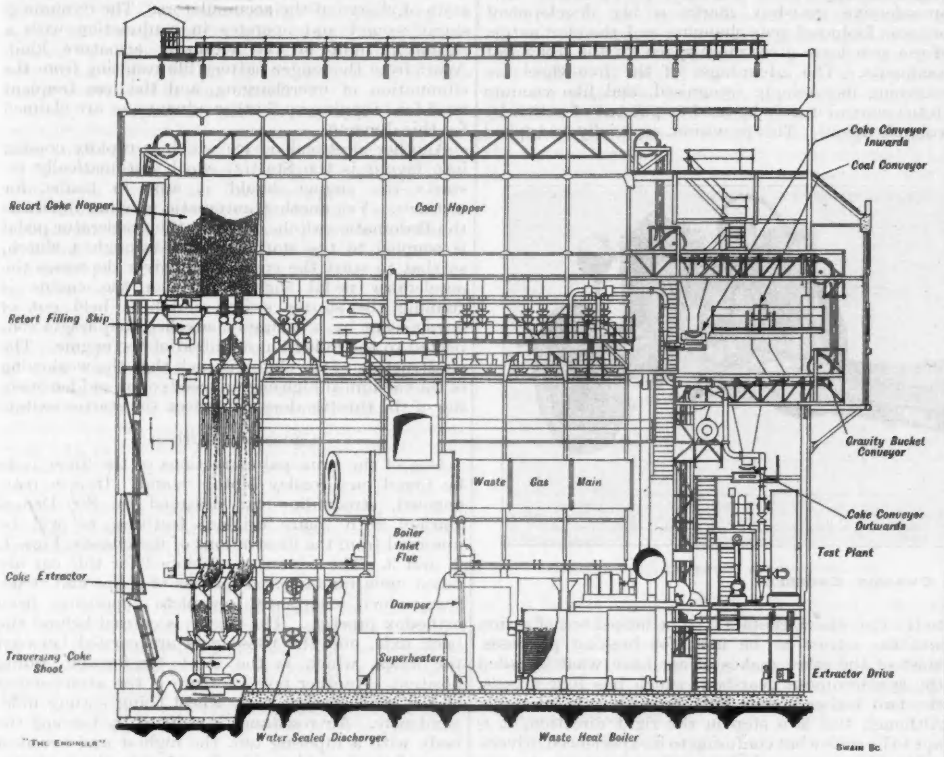
Coke Skip-Filling Station

For the purpose of returning the coal out of store into service the travel of the conveyor B is reversed, and it is supplied through a travelling hopper with a short feeder belt, 6ft. long, beneath the opening, to check the impact of the load on the main belt. The coal is picked up from the dump by a travelling grab crane, driven by steam, of 2 tons capacity, which has a radius of 50ft. beyond the centre line of the main conveyor.

On its way from the conveyor A to the retort house the coal, whether it goes directly or *viâ* the dump, must, probably, be passed through a crusher, as the aim is to purchase "run of the mine" coal. So two 30in. by 30in. Jeffery coal crushers are arranged in the Junction House. They are capable of breaking down coal from a maximum size of 22in. cube to 2in. and under, and are driven by 40 H.P. motors. Either one will pass 80 tons of coal per hour. There is, however, a by-pass shoot over the crushers for use when small coal is being handled.

The crushers deliver into the boot of the conveyor C, which goes to the retort house. This conveyor is also of the Robins type, but is 24in. wide, as its capacity is intended to be 80 tons per hour. It is 212ft. long, has a rise of 55ft., travels at a speed of 225ft. per minute, and is driven by a 10 H.P. motor. Towards the upper end this conveyor runs over a Westminster weighing machine, which is guaranteed to give the weight of the coal delivered to within 0·5 per cent.

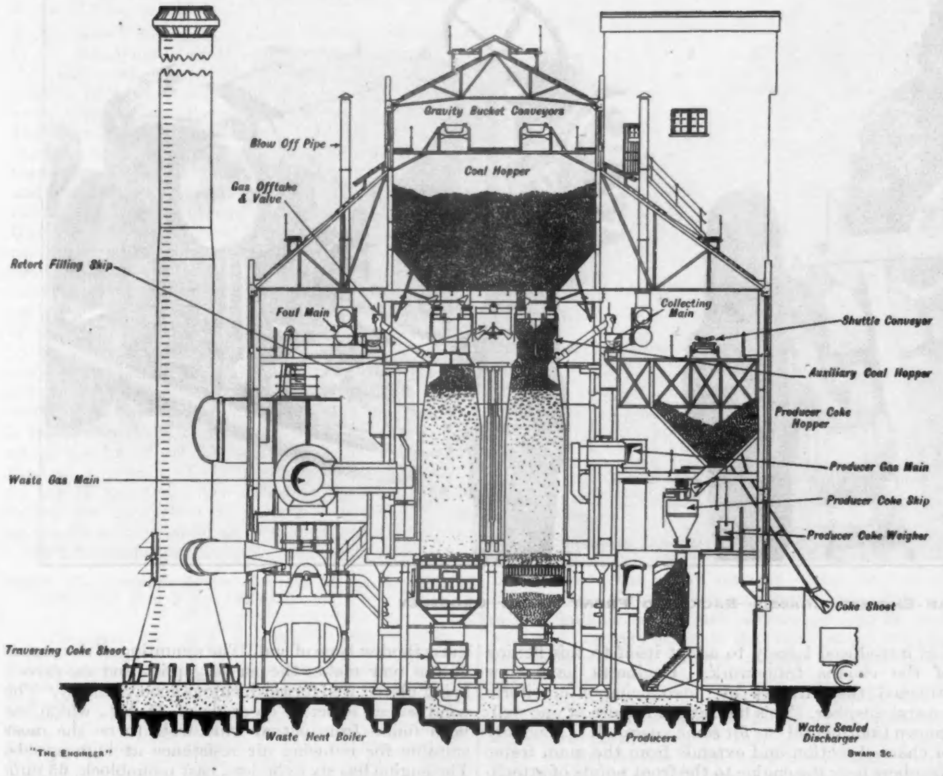
The conveyor C delivers into a gravity bucket conveyor that encircles the retort house in a vertical plane. Its route can best be followed in the drawing of the retort house. This conveyor, which has a capacity of 100 tons an hour, first takes the coal up and over the bunkers that feed the retorts, and then drops down to pick up the resultant coke and raise it up to a level for feeding the outgoing conveyor D.



Retort House—Longitudinal Section

This conveyor D has a capacity of 50 tons of coke per hour and has a length of 142ft., while its rise to the screening house is 42ft. It runs at 260ft. per minute, and is driven by a motor of 5 H.P.

In the screening house the coke is passed over rotary grizzlies and vibrating screens to separate it out into sizes ranging from over 2½in. down to breeze. All these sizes are sent into separate bunkers. It is noteworthy, in view of the usually unpleasant dusty atmosphere of such operations, that, while we climbed to the top of the screening house immediately after a charge had been passed through, the air quickly cleared, the floor was already in process of being swept up, and the surroundings of the plant gave little indication of the activities within. We also noticed that the chutes leading into the hoppers were well extended to leave the coke little free fall, with a consequent reduction in the amount of fines produced.



Retort House—Cross Section

The coke can be taken out of the hoppers to several alternative destinations, by means of two conveyors E and F beneath the outlets—see sectional elevation—each about 70ft. long, and both running towards the centre, or it may be discharged directly into carts for dispatch from the works. The conveyors may deliver to a belt conveyor G, which takes coke back to the retort house for use in the producers and the Lancashire boilers, or to another conveyor H for delivery to an automatic skip-filling hopper from which it is removed by means of an overhead steam crane to the coke storage yard. Coke may also be passed directly from the conveyor D to the conveyor J, and thence, by means of the grab crane, to a stock pile. This pile can be recovered by using the crane and reversing the conveyor J to take it back to the screening plant. There is also a coke-washing plant for medium sizes that is served by the skip crane.

The Laboratory.

Before closing this account some reference should be made to the laboratory, which is built on similar lines to the engine-house and the corresponding meter house, which go far to assist in the scientific control of the works, while the mess and lavatory accommodation for the staff is excellent.

Literature.

SHORT NOTICES.

Mechanical Refrigeration. By Hal Williams. Fourth edition. London: Sir Isaac Pitman and Sons, Ltd. 1933. Price 20s.—When a book reaches its fourth edition, and that only six years after the third was published, it may be judged with certainty that it has been accepted as the standard work on the subject. When, in addition, a glance at the preface indicates the possession by the author of a delicate sense of humour, one is quite unreasonably prepossessed still further in favour of his book. Whereas, when the third edition was published only two years after the second, the author found that the necessary alterations brought about by the ordinary course of development were few, in this new edition many new illustrations have been included to mark the march of progress. Notable developments have been made in the use of "dry ice"; in refrigerated trucks and other vehicles; in the freezing of fish and meat, and also in the design of abattoirs. The reviewer fears that Mr. Hal Williams is likely to suffer for the rest of his natural life the mixture of gratification and embarrassment he has already endured on three occasions, at intervals, caused by the readiness of the sale of his book and the rapidity of development of mechanical refrigeration.

The Sanitation of Water Supplies. By Murray P. Horwood. London: Baillière, Tindall and Ccx. 1932. Price 7s. 6d.—This book, an American one, is intended particularly for students of municipal sanitation and public health. While the author points out that the subject may be divided into the three aspects, laboratory, public health, and engineering respectively, he is mainly concerned with the first two. Opening with a short history of the rise of Municipal Sanitation and Public Health, the remainder of the first seventy-seven pages is devoted to sources of and the development of water supplies; the requirements of a potable supply and the effect of water as a vehicle for disease. Nearly one hundred pages more are then devoted to purification, softening, filtration, and disinfection. The examples quoted, and the methods described, as might indeed be expected, are all those of the country of origin of the book—America. As a general survey, therefore, of American conditions the volume has some interest for engineers in this country.

Electrical Transmission and Distribution. By E. T. A. Rapson. London: Humphrey Milford. Price 12s. 6d.—This is a book written for students, but it may possibly also prove useful to engineers who have not hitherto given much attention to electrical transmission and distribution problems. It is based on notes compiled by the author in lecturing on the subject to technical college students and is intended to serve as an introduction to the specialised treatises on this branch of electrical engineering. Many questions are set and answered and overhead lines and cables are covered. Descriptions are given of all the modern cables and feeder protective gear. A somewhat notable feature of the book is the inclusion of a chapter on the British "grid," in which the well-known advantages claimed for the scheme are set forth. On the whole, the book covers the subject pretty well, but no reference appears to be made to voltage regulation by means of A.C. feeder regulators, which show signs of meeting with widespread application.

The Mechanism of the Car. By Arthur W. Judge. Second edition. London: Chapman and Hall, Ltd. 1933. Price 4s.—This little book is Volume III. of Motor Manuals, a series published with the object of meeting the needs of motor owners and users. Since the first edition of the book was published in 1925 considerable progress has occurred in the design of automobiles, and a careful revision of the work and the inclusion of some new matter has been found necessary. The book deals in successive chapters with all the various parts of a car, such as the chassis, axles and steering, the clutch, gear-box and other transmission details, brakes, and wheels. It is not concerned with the engine, as the title might be thought to imply. Modern developments such as pre-selective and synchro-mesh gear-boxes are described, as well as hydraulic, pneumatic, and vacuum-servo brakes.

Motor Car Show at Olympia.

No. I.

Although the motor car exhibition which is being held at Olympia under the auspices of the Society of Motor Manufacturers and Traders will no doubt prove as attractive to the public as most of the twenty-six annual Shows which have preceded it, much of the curiosity of motor vehicle users has already been satisfied by the previous publication of the chief features of the 1934 products of the principal British makers. It is claimed that there are altogether some 500 firms exhibiting, but by far the largest number is to be found in the accessories and garage and service equipment sections. A notable development in this connection centres in tools for the complete renovation of engine cylinders and valves, and appliances for testing the roadworthiness of cars, as and when required. Particular interest will be found by engineers in the testing plants to check performance and brake adjustments, some of which can now be applied while cars are being lubricated.

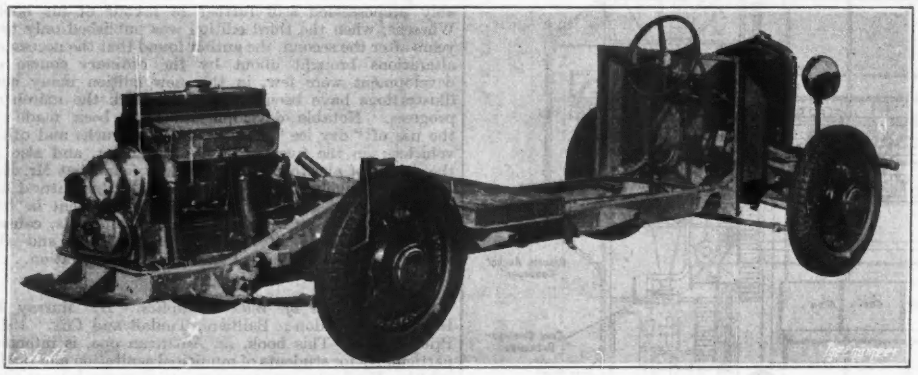

Fig. 1—Rear-Engined Chassis—Crossley

The motor boat section is well patronised by the leading builders. The exhibits range from an "Aquaplane" for towing behind motor boats for "surf-riding," to a full-powered cabin cruiser. In the latter type of craft there appears to be a growing tendency to use two medium-powered engines instead of one large engine, a change which gives increased reliability and easier handling of the boat. A feature of this section is the increased speeds of small craft, such as dinghies and yacht tenders. Nearly all the inboard motor boat engines are now provided with electric lighting and starting equipments, and a dashboard with instruments and switches. There is a good range of compression ignition engines, some of which are light enough in weight for installing in 30ft. cruisers.

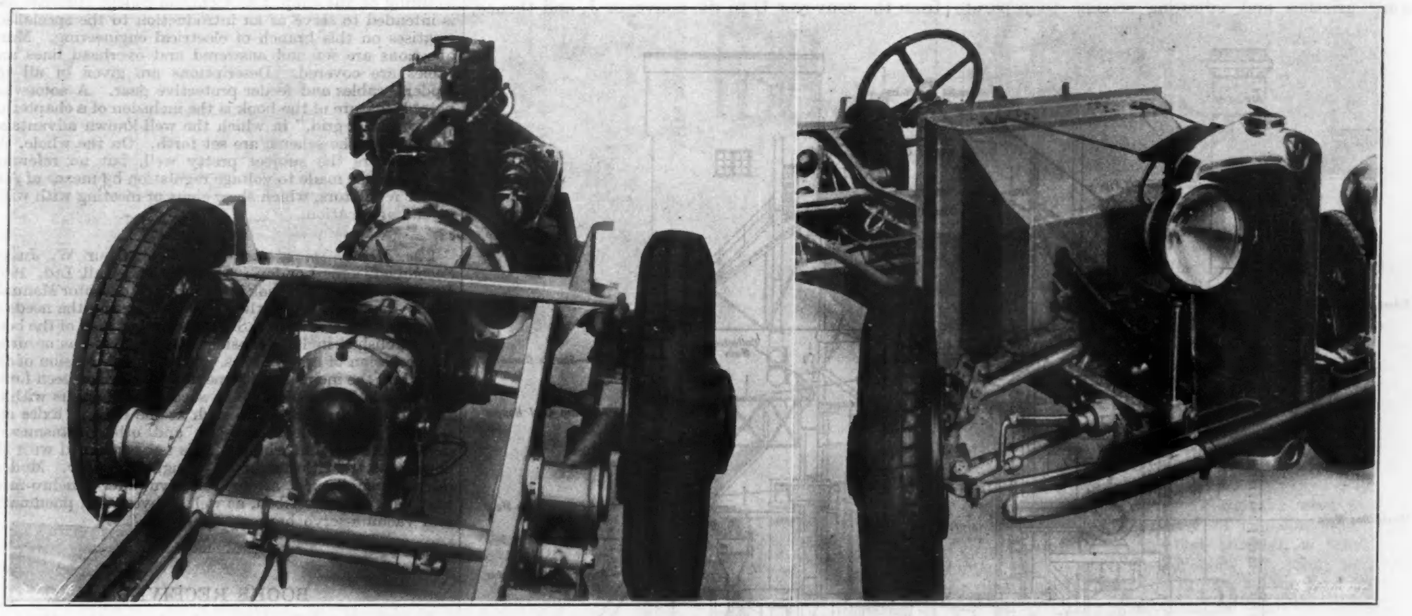

Fig. 2—Rear-Engined Chassis—Back and Front Axles—Crossley

With regard to the new car designs, as most of our readers are already informed, the outstanding feature this year has to do with gear-box construction and design. The improvements which have been introduced are of various kinds—some more complicated than others—to enable easy and quiet changes of gear to be effected. The most prominent perhaps is the Wilson epicyclic gear-box, which was originally introduced by the Armstrong-Siddeley Company, and latterly adopted by the Daimler and allied companies in conjunction with the fluid fly-wheel. The pre-selective gear-box marks a big development towards foolproof gear changing and the elimination of the gear lever gives more space for the front seat occupants. The advantages of the free-wheel are becoming increasingly recognised, and like vacuum clutch control it may be used or put out of action by a simple device. This provision, especially as applied to the free wheel, enables it to be locked out of action and the engine to be used for braking purposes. Most of the other makes of car have what is called the synchro-mesh gear-box, which has four speeds, the two higher speeds only being always in mesh. Although this is a step in the right direction, it is apt to be somewhat confusing to inexperienced drivers.

Much prominence is being given in the motor car industry to the stiffening of the chassis framework. Some of the more popular makers of cars, on account of lightness, have not hitherto put sufficient metal into the frames, or if they have done so have put it where it is least needed. The result has been twisting and distortion of the framework, which has caused troubles with the body work. The Weymann body was introduced largely to adapt itself to this flexing of the chassis framework. Engineers have now stiffened their frames by introducing a cruciform central member. This has been a feature of one well-known Continental car for some years. It is generally of channel section and extends from the main frame members near the engine to the front points of attachment of the rear springs. The centre of the cross is made hollow, so that the propeller shaft from the gear-box to the rear axle may pass through it. This form of construction will go a long way towards preventing the body noises common in some makes of car, which are produced by the flexing and relative movement of the parts of the wooden body frame.

As regards ignition, the great majority of 1934 cars will have the coil and battery form with automatic timing over part of the range and manual control for the rest. The Scintilla vertical magneto, which we described in connection with last year's Show, will also be seen on some cars. This device has the merits of accessibility and synchronous timing, with automatic control. Electricity will play a greater part than ever in next year's cars. Ignition, starting, lighting, supplying fuel to the carburetter from the tank, wind-screen wiping, and horn blowing will all be done by electrical means. The firm of Lucas is introducing for these purposes an improved form of dynamo, the output of which varies with the state of charge of the accumulators. The dynamo is shunt wound and operates in conjunction with a regulating unit of the vibrating armature kind. Apart from the longer battery life resulting from the elimination of overcharging, and the less frequent need for 'topping up," other advantages are claimed for this dynamo.

Another electrical device which is rapidly coming into favour is the Startix, which automatically restarts the engine should it stop in traffic, for instance. Yet another automatic starting device is the Pedomatic switch, in which the accelerator pedal is coupled to the starter switch through a clutch, so that to start the engine the driver depresses the accelerator pedal slightly. When the engine is running the starter switch clutch is held out of engagement by a vacuum-controlled diaphragm connected to the induction manifold of the engine. The construction of the clutch is such that the weakening of the vacuum at high engine speeds or on sudden opening of the throttle does not affect the starter switch.

Crossley Motors.

One of the principal attractions of the Show is to be found on Crossley Motors stand. It is a rear-engined, stream-line car designed by Sir Dennis Burney with many original features, as will be observed from the illustrations of the chassis, Figs. 1, 2, and 3. The advantages claimed for this car are based upon fundamental reasons of shape and structure, which incorporate complete departures from orthodox practice. The engine is carried behind the back axle, and the passengers are carried between the axles, which is the most comfortable riding position. Another novel feature is the arrangement of the road springs, each wheel being sprung independently. Air resistance is reduced by forming the body with a tapering tail, the highest and broadest part of the body being in front, as in the case of a bird. A self-changing pre-selective gear-box of the Wilson type is placed immediately in front of the back axle, and the final drive is by spiral bevel gear, and thence through a short cardan shaft universally jointed at both ends to each rear wheel. The body is built exceedingly low without loss of headroom, as there is no transmission shaft from front to rear, as in the orthodox type of car. The mounting of the engine at the rear makes the car very quiet, and the driver, being placed well forward, enjoys good visibility. The wind screen is set at an angle of 35 deg., which has been found from actual wind tests to be the most suitable for reducing air resistance at high speeds. The engine has six cylinders, cast monoblock, 65 mm. bore by 100 mm. stroke, the R.A.C. rating being 15·7 H.P. It has overhead valves and forced lubrication to all main bearings, and also to the big end bearings. The carburetter and magneto are very easy of access. By lifting the rear bonnet the engine can be reached with ease, as there are no wheels or wings to lean over. The Wilson gear box gives four speeds. The wheel base of the car is 9ft. 8in.; front track, 4ft. 8in.; rear track, 3ft. 7in.; overall width, 5ft. 6in.; ground clearance, 8in.; and turning circle, 35ft.

(To be continued.)

World's Oil Supplies.

By JOHN B. C. KERSHAW, F. Inst. Fuel.

THE issue of THE ENGINEER for August 7th, 1931, contained an article by the writer in which the position of the Fuel Oil Industries at that date was discussed. In the present article the figures of the earlier one have been brought up to date, and their bearing upon the prospects of the various processes now being employed for the production of oil from coal is considered in some detail.

There is a tendency at the moment, especially amongst financiers and politicians, to raise expectations unwisely concerning the possibility of extracting oil from coal, and thus of making this country independent as regards our future supplies of fuel oils. It is advisable therefore that the real facts of the position should be made clear and published as widely as possible, in order that the magnitude and difficulties of the problem may be realised more fully by the general public. The decision of the Government to grant a rebate of the Excise Duty amounting to 4d. per gallon upon home-produced petrol after April 1st, 1934, has certainly rendered the prospects of these processes more favourable. The writer is doubtful, however, whether more than one or two of the processes will be able to produce light oils at a price which can compete with the imported petrol, even with this rebate of half the Excise Duty to help them, and the figures given below for our consumption of petrol and other light oils indicate what an enormous development of these new processes will be necessary before we are rendered independent of our external sources of supply.

THE WORLD OUTPUT OF CRUDE OIL.

Table I. gives the official figures for the world production of crude oil in the pre-war year 1913 and for the post-war years 1922 to 1932, expressed in thousands of barrels. The percentage of the total supply which comes from the United States is given in the last column of the table. The figures show that the world production of crude oil attained its peak in 1929, when it reached the huge total of rather over 1000 million barrels, which is equivalent to 42,000 million gallons. Since 1929 the world production has been curtailed, largely owing to the trade depression and consequent falling off in demand, and for 1932 the total output of the oil wells had fallen to 781,845,000 barrels, or by 22 per cent. The United States proportion has also fallen away very rapidly, for fresh oilfields have been developed and brought into operation in various quarters of the world since 1923, when the United States oilfields supplied 72 per cent. of the total world production of mineral oil. The percentage has now receded to 59·9, which represents a reduction of 13·1 per cent. in the ten years, and the predominant position occupied by the United States oil companies in the world market seems now nearly ended. The position is made clearer by the two diagrams printed below, which are based on the figures of Table I., and the gradual approach of the two curves in Diagram 1 to the 50 per cent. line indicates that by 1936 or earlier the production of "Other countries" in the aggregate will be equal to, if it does not exceed, the United States output.

TABLE I.—*Comparative Figures for the Total Production of Crude Oil in the Years* 1913–1932, *from Figures Compiled by the U.S. Geological Survey (in thousands of barrels of 42 U.S. gallons).*

Year.	World.	U.S.A.	U.S. percentage.
1913 ..	.. 383,547 ..	.. 248,446 ..	.. 64·7
1922 ..	.. 858,715 ..	.. 557,531 ..	.. 64·9
1923 ..	.. 1,018,900 ..	.. 732,407 ..	.. 72·0
1924 ..	.. 1,012,927 ..	.. 713,940 ..	.. 70·4
1925 ..	.. 1,067,566 ..	.. 763,743 ..	.. 71·5
1926 ..	.. 1,095,934 ..	.. 770,874 ..	.. 70·4
1927 ..	.. 1,262,582 ..	.. 901,129 ..	.. 71·4
1928 ..	.. 1,324,733 ..	.. 901,474 ..	.. 68·0
1929 ..	.. 1,482,517 ..	.. 1,006,587 ..	.. 67·9
1930 ..	.. 1,418,723 ..	.. 898,011 ..	.. 63·3
1931 ..	.. 1,372,532 ..	.. 851,081 ..	.. 62·0
1932 ..	.. 1,305,563 ..	.. 781,845 ..	.. 59·9

NOTE.—The 1932 figures are not estimates, but are the Bureau of Mines figures.

TABLE II.—*World Production of Crude Oil (in thousands of barrels) for Four Years,* 1929–32.

Country.	1929	1930.	1931.	1932.
United States ..	1,007,323	898,000	851,081	781,845
Russia*	100,583	136,835	165,576	158,050
Venezuela	137,472	137,675	116,613	116,300
Roumania	34,689	41,680	49,127	54,160
Persia	42,145	45,420	44,376	49,470
Dutch East Indies ..	38,072	40,100	35,539	39,000

Peru	13,422	17,458	10,089	9,900
Equador	1,350	1,559	1,762	1,595
Other countries ..	25,805	22,092	25,640	22,921
Totals	1,484,041	1,418,725	1,372,532	1,305,563

* N.B.—Includes Sakhalin production.

Table II. gives the details of the crude oil production of the leading individual countries for the past four years, and from this table it will be seen that Russia and Venezuela are the two countries which, after the United States, are contributing the largest share to the world's supplies of mineral oil. Roumania, Peru, the Dutch East Indies, and Mexico follow in the order named, and it will be noted that some of these countries have reduced their output for 1931 and 1932. It would be premature to conclude, however, that these particular oilfields are exhausted, for their restriction of output has been dictated chiefly by the desire to conserve their supplies until the demand has increased and the price obtainable for the crude oil has reached a more remunerative figure.

Considering now the statistics for the consumption of oil in this country, Table III. gives the figures published by the Board of Trade, showing the imports of oil for the pre-war year 1913 and for the post-war years 1928 to 1931, expressed as thousands of gallons.

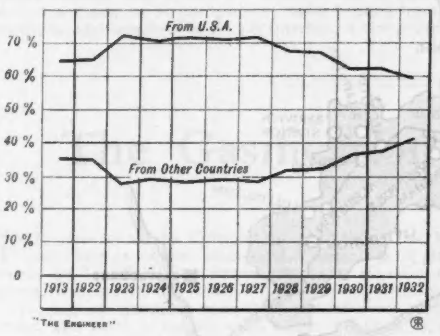

DIAGRAM I.—OUTPUT OF CRUDE OIL

TABLE III.—*The Imports of Oil into the United Kingdom (in thousands of gallons) for the Pre-war Year* 1913 *and for the Post-war Years* 1928–31.

Character of import.	1913.	1928.	1929.	1930.	1931.
Crude oil	1,108	498,001	487,348	460,968	344,370
Refined oils—					
Petrol	100,858	734,737	810,084	954,609	905,205
Fuel oil	161,011	450,876	405,610	491,089	485,814
Lamp oil	157,141	189,763	255,032	245,792	270,946
Lubricating oil ..	67,962	105,429	98,018	101,937	97,531

The total imports of these five types of oil are seen to have increased from 488 million gallons in 1913 to 2103 million gallons in 1931, or more than fourfold.

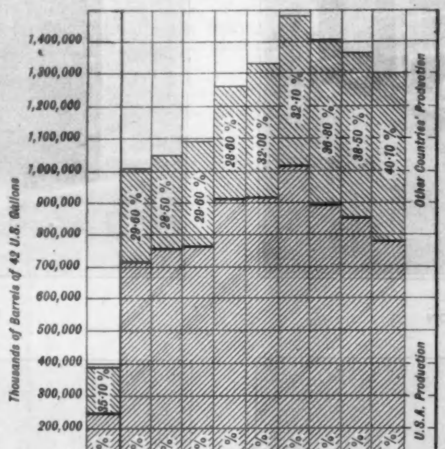

DIAGRAM II.—OUTPUT OF CRUDE OIL

If one takes the petrol imports alone the increase in the same period is seen to have been from 101 million gallons up to 905 million gallons, or ninefold, and one may estimate that the consumption has kept pace with the imports, in spite of the increased storage capacity at the importing centres.

The aggregate value of the fuel oil imported in 1931 amounted to close upon 25 million pounds sterling, at the ports of entry—that is, before the Excise Duty or distribution costs have been added to the original cost of the oil. More than one-half of this total represented the cost of petrol, for in 1931 the total value of imported petrol was £13,671,444, which is equivalent to an average price of 3·62d. per gallon at the port of entry. Lamp oil came next with a value of £3,499,883, equivalent to 3·10d. per gallon; while our imports of crude oil cost us £2,974,662, or 2·07d. per gallon. The balance of our imports was made up of lubricating oil, valued at £4,018,021, and fuel oils, valued at £3,499,883, and the latter cost us on the average only 0·98d. per gallon at the port of entry. It is rather unsatisfactory to note, however, that our imports of crude oil have declined during the last few years, and are now only one-third of the volume they were in 1913. There is no reason why the cracking and refining of crude oil should not be carried on in this country rather than in the country of origin, and it might be well if the excise authorities took some steps to encourage the import of crude oil rather than of the refined products which are obtained from it.

Finally, in comparison with the above figures, the estimated production may be given of the existing plants for obtaining fuel oils from coal when the extensions now in progress are completed, and the new Bergius plant for the hydrogenation of coal is in operation. We shall then be in a position to produce about 80 million gallons of light fuel oils per annum or about 9 per cent. of our present consumption, and this shows that many years must elapse before the whole of our requirements of light and heavy fuel oils can be met by our home producers.

Future Prospects of Low-Temperature Carbonisation.*

THE present-day low-temperature carbonisation industry is on a small scale. Not more than about 1 per cent. of the household fuel burnt in open grates is produced by low-temperature carbonisation processes. The economics of these processes depend essentially on the difference in price between small and large coal. An expansion of the industry must of necessity have a profound influence on the price, both of the raw material for the process and of the finished product, and it is important to consider, whether, should supplies of low-temperature fuel become abundant, the "manufactured product" could successfully compete with the "raw material."

The quality of coal suitable for low-temperature carbonisation for the production of a household fuel depends to such an extent on the process used that it is not possible to generalise. For example, one process may be able to deal only with non-caking or feebly caking coals, whilst another may demand a strongly caking coal for its successful operation. The choice of process, or of coal for a process, can be determined satisfactorily only by trial.

Supplies of cheap coal suitable for low-temperature carbonisation (*e.g.*, of low ash content) are not unlimited. An industry, established at the collieries, swollen to such a size as to be able to supply the major part of the nation's household fuel, would have to pay a price not much, if any, less than the average pithead price of all grades of coal, which is, at present, about 13s. 3d. per ton. The finished product would compete with large house coal, now commanding a price at the pithead of about 27s. per ton.

Theoretically, a low-temperature coke should be valued at a higher figure than coal; for a fuel that retains the qualities of coal for use in open grates and is also smokeless has material advantages. Nevertheless, it is doubtful whether such advantages of quality as a low-temperature coke might possess would cause it to be valued more highly than house coal if both were equally available. Moreover, it must be remembered that the market for house coal has been decreasing, owing to the substitution of gas and electricity and of central heating plants burning high-temperature coke. Equally, it must be presumed, the market for a low-temperature coke as a domestic fuel might be decreasing.

When considering the future prospects of low-temperature carbonisation as an industry, therefore, it would not be wise to count on a greater difference in price between the raw material and the finished product than at present exists between the average price at the pithead of all grades of coal and the price of house coal, a difference of about 13s. 9d. The operating costs for a 200-ton plant would be about 10s. per ton of coal carbonised, equivalent to about 14s. 3d. per ton of fuel produced.

With expansion of the industry, closer attention could be paid to the tar and gas as sources of revenue. Low-temperature tar, if reasonably free from solid matter, is a suitable raw material for hydrogenation, and the whole of it, including the pitch fraction, can be so treated. When bulk supplies of low-temperature tar are available, hydrogenation should be profitable. The gas is usually of high calorific value, being rich in hydrocarbons, a fact which would commend it for use as a motor fuel, inasmuch as, for a given capacity of cylinders for compressed gas, a motor lorry, for example, would have double the touring range if the calorific value of the gas were 900 B.Th.U. instead of the 450 B.Th.U. usual for coke-oven gas. A gas rich in hydrocarbons could also be subjected to pyrolysis (*i.e.*, heat treatment) for the production of benzene.

General Conclusions.—At the present time, the difference in value between the raw material (small coal) and the finished product (domestic fuel) being great and the output being small, the manufacture, by a suitable process, of a low-temperature coke of good quality should prove a profitable undertaking for colliery companies.

With the growth of the low-temperature carbonisation industry to the point where most of the domestic market would be met, the prices of small coal and house coal (and, thus, of the manufactured fuel) would approach each other, so that the margin allowable for operating costs would be restricted. It is estimated that a plant having a throughput of less than 200 tons of coal per day might not then be sufficiently profitable.

IT is proposed that a Bill should be promoted to form a Joint Municipal Transport Board operating throughout the area of nine local authorities in South-East Lancashire and East Cheshire, with Manchester and Salford as the focal centre of the new system.

---

* From a leaflet, Memorandum No. 12, issued by the Utilisation of Coal Committee of the Institution of Mining Engineers.

A New Rural Electrification Scheme.

OF the rural electrification schemes that have been made possible by "grid" secondary lines, the Ringmer and District Electricity Undertaking, embracing an area of some 63 square miles of picturesque country, should easily prove to be one of the most successful. With several important industrial concerns at the Lewes end and agricultural and residential districts, as indicated in the map, Fig. 1, the area which extends along under the lee of the South Downs between Lewes and Eastbourne offers a good field for electrical enterprise. Factories, farms, country houses, villas, and shops are now reaping the benefits of electricity derived from the Ringmer and District Supply Company, Ltd., financed by Johnson and Phillips, Ltd., of Charlton, S.E.7, who manufactured and erected all the plant, cables, and overhead lines. Broadly speaking, the area lies between Lewes and Ringmer in the centre, Plumpton to the west, and Alfriston to the south. A special order was granted by the Electricity Commissioners to the company in 1930, and an efficient and extensive distribution system has since been provided.

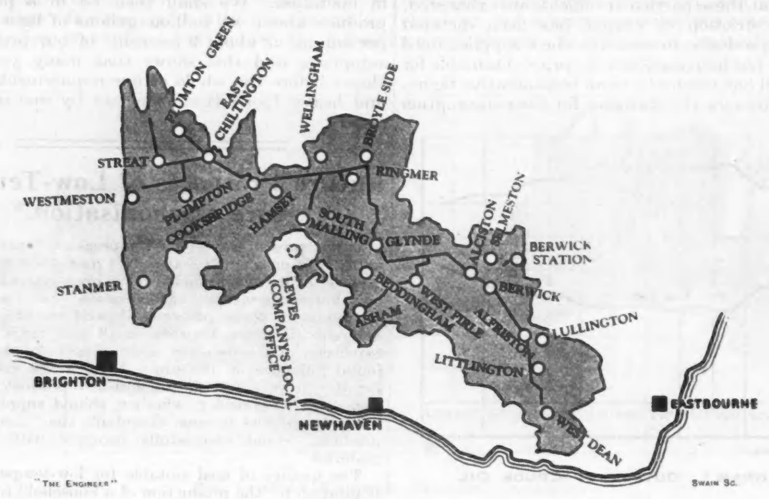

Fig. 1—Map of Ringmer and District Electrified Area

Three-phase current at 10·5 kV is supplied to the undertaking by the Central Electricity Board through the sub-station—Fig. 2—which is tapped on to the 33-kV secondary "grid" line between Eastbourne and Newhaven. It is situated at Asham, Rodmell, just beyond the Lewes urban boundary, and contains two Johnson and Phillips 5000 kVA automatic on-load tap-changing transformers, which reduce the pressure to 10·5 kV for the Ringmer transmission system. In the company's sub-station adjacent to that belonging to the Central Electricity Board there are two incoming and five outgoing high-tension feeder panels with metering and protective equipment for the supplies at this point. While the two incoming panels control the 5000-kVA transformers, the outgoing panels deal with the supplies to the Alpha Cement Company, Ltd., Carbo Products, Ltd., and to the company's main transmission system.

The Cement Company's main works are on the sub-station site and a supply is given to them through two 1500-kVA Johnson and Phillips outdoor transformers, which reduce the pressure from 10·5 kV to 440 volts for motors in the factory. Two 500-kVA transformers of the same type and make installed about 500 yards distant are supplied through a length of cable and serve for providing the Cement Company's smaller works with current. Overhead 10·5-kV lines are employed, mainly for the transmission of electrical energy from the supply company's main sub-station to the distribution centres. This transmission system is, roughly speaking, in the form of a short stemmed T with the Asham main sub-station at the base. On the north boundary of Firle Park at Gibraltar Farm the stem meets the main lines and at this point there is a special four-member pole, as shown in Fig. 4, which carries switchgear for controlling the high-tension lines running to the east of the Alfriston area in the south, and north to Ringmer, with a subsequent veering round to the west to Plumpton. The switchgear on this pole consists of the new Johnson and Phillips "E.K.C." oil circuit breaker with an automatic reclosing device which, when minor self-clearing faults occur, recloses the breaker three times in succession with increasing time lag on each occasion. After the final reclosing the circuit breaker remains open and an indicator shows which section of the line is giving trouble. Obviously the device offers the advantages of avoiding the necessity for a lineman to tramp perhaps miles in order to reclose a breaker that has been opened by a minor fault, and consequently reduces the time the supply is interrupted.

The main overhead feeder from the Asham sub-station to the Gibraltar Farm four-member junction pole, shown in Fig. 4, consists of 0·05 square inch equivalent steel core aluminium conductor, whilst the lines running north and subsequently west and east and then south are composed of 0·025 square inch equivalent cadmium copper. For the most part the high-tension conductors are carried on wooden poles, as shown in Fig. 5, in which the pole to be seen in the foreground carries a 11-kV 25-kVA transformer and fuses. The design of the cross arms carrying the lines is said to be the outcome of much investigation in connection with eliminating troubles caused by birds.

Although for the most part the high-tension conductors are carried on wooden poles, concrete poles are also employed, as shown in Fig. 6, which illustrates a terminal pole with an 11-kV 25-kVA transformer, high-tension fuses, low-tension switch, and three outgoing low-tension lines. While the pole span averages 425ft. on normal runs of line, owing to the particular configuration of the ground in some places spans of between 450ft. and 550ft. have been adopted. Pole-mounted transformers are provided at convenient points for reducing the line pressure to 230 volts single-phase for lighting and for general domestic purposes, and to 400 volts three-phase for power purposes. Generally speaking, the outgoing low-tension leads from the transformer are taken to a waterproof ironclad switch and fuse and then to insulators fixed to the pole, from

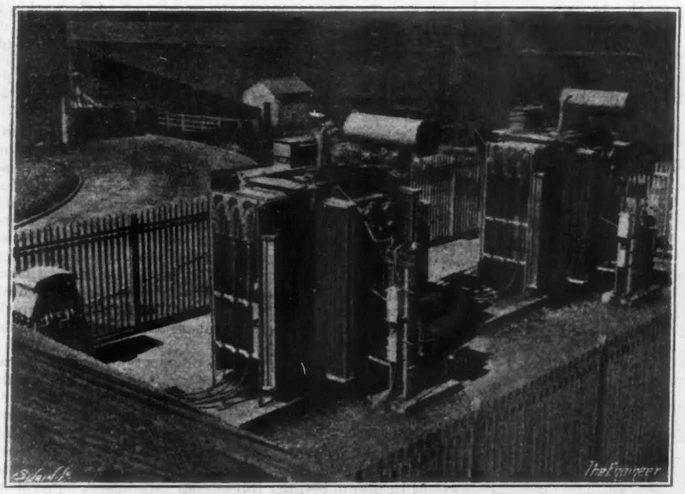

Fig. 2—The Asham Sub-Station

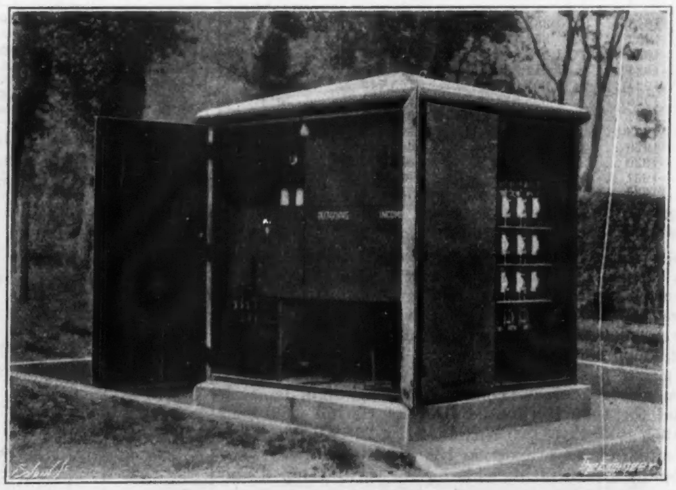

Fig. 3—Kiosk at Alfriston

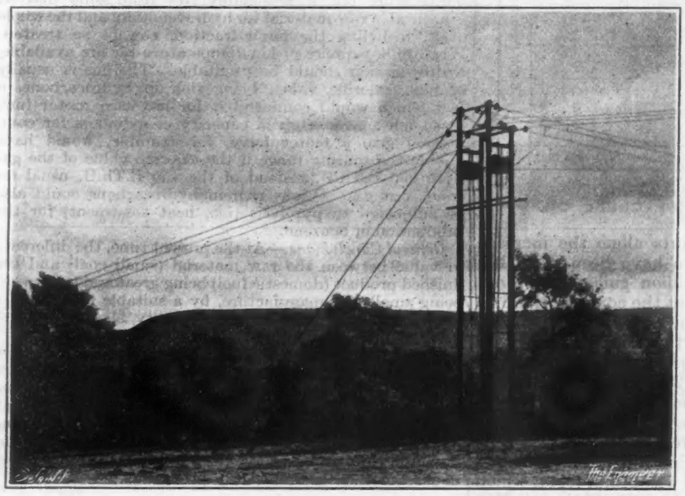

Fig. 4—Junction Pole at Gibraltar Farm

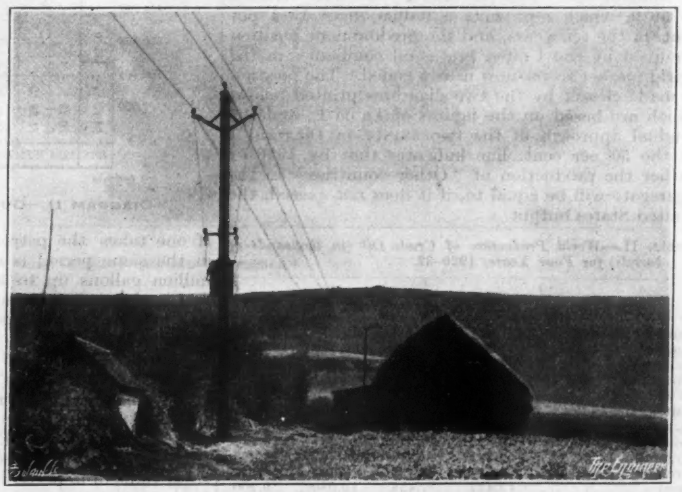

Fig. 5—Straight Line Wood Transformer Pole

which the low-tension service lines are run to the consumers' premises.

Except in a few places in which it has been necessary to preserve the special amenities of the district by the use of underground cables, the low-tension distribution system is overhead. Service lines consisting of " P.B.J." cable and bare copper conductors are connected to the distributors by means of Johnson and Phillips "Wonpeace" insulators fixed to the pole and building respectively, while the service is continued into the premises by rubber insulated fire-resisting cable passing through porcelain tubes. Where a row of terraced houses is to be supplied special low-tension lines have in some cases been erected and services are tapped off at intervals for supplying groups of houses from convenient points, the special fire-resisting cable being run along the faces of the houses. Individual services are then taken off to each consumer through cast iron tee boxes. Where it has been necessary to employ underground distribution cables a length of high-tension cable has been brought from a neighbouring terminal pole outside the area to be supplied and has been connected to a combined transformer and feeder pillar which feeds low-tension distributors, all service connections to the individual consumers also being kept underground. For a relatively large demand in places in which the amenities must be preserved, such as in the old world village of Alfriston, a kiosk sub-station has been provided, as shown in Fig. 3.

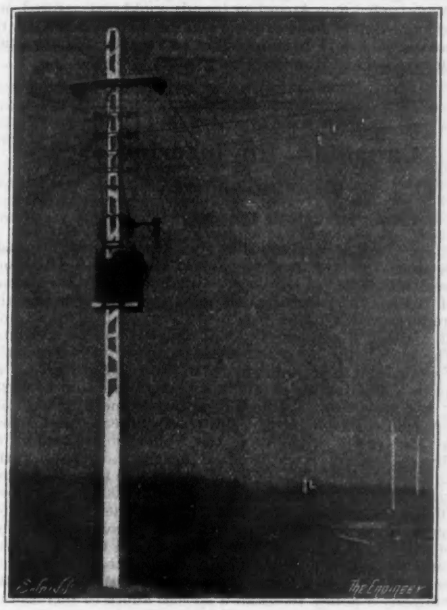

Fig. 6—Terminal Concrete Pole with Transformer

Tariffs have been framed to attract all classes of people, such as ordinary power users, farmers, and domestic and business consumers. For power demands above 5 horse-power there is a flat rate tariff of 1½d. per unit, while private residences and hotels can adopt a two-part tariff in which the fixed charge is 20 per cent. of the rateable value of the premises and the running charge 1d. per unit for all units consumed. For an "off peak" water heating load the price is only ½d. per unit. At present the company's output is approximately three million units per annum with an average maximum demand around 900 kW, produced mainly by the Alpha Cement Company, Ltd., and Carbo Products, Ltd., but domestic and small power consumers are being connected to the system at a very encouraging rate. Consumers' premises are wired, when necessary, on hire purchase terms, the actual work being undertaken by local contractors approved by the company, which specifies how the work shall be done. The wiring system generally employed is the Johnson and Phillips surface system, in which tough rubber sheathed cables are employed. Under the assisted wiring scheme payment for the installation is extended over a period of three years and is made through the medium of slot meters calibrated so that a small charge towards the cost of the wiring is added to the normal cost per unit consumed. The scheme is generally limited to the smaller types of properties, on which it has proved distinctly helpful.

Apart from this assisted wiring scheme the company offers very attractive terms to its consumers for the hire of domestic electrical apparatus, such as cookers, fires, water heaters, wash boilers, &c. Cookers may be hired for as low a charge as 5s. per quarter, water heaters from 4s. upwards, and fires from 2s. 3d. per quarter. A hire purchase scheme for electrical apparatus is at present under consideration. At 80, High-street, Lewes, there is an attractive showroom, in which all the latest electrical devices are to be seen and advice is given to potential consumers.

During a visit to the area last week we inspected several of the largest consumers' premises, including those of the Alpha Cement Company, Ltd. (formerly Cement Industries, Rodwell, near Lewes), and the Glyndebourne Festival Opera House, which will be opened next spring or summer. Glyndebourne is a Tudor house situated in the midst of beautiful country, and the addition of the Opera House gives it new artistic interest. The stage mechanism consists of over seventy overhead sets, two stage lifts, stage wagons, and electrically operated steam-raising apparatus for stage effects, while a newly designed mechanism, said to be hitherto unknown in England, has been installed for operating the proscenium curtain. The stage lighting system, which is considered to be the most modern in the world, is controlled from a special cabinet facing the stage, for which there are seventy spot lights under separate dimming control. Other important consumers are the East Sussex Agricultural Institute, Plumpton, and Plumpton Place, the residence of Mr. Edward Hudson. The consulting engineer to the Ringmer and district electricity undertaking is Mr. W. O. Rooper.

The Gasification of Town's Refuse.

FOR some time the Corporation of Burnley has had under test at its destructor station a new type of plant made by Whitfield Gas Producers, Ltd., 82, Victoria-street, London, S.W.1, which we had an opportunity of inspecting in operation recently. Actually, we understand, the plant is dealing with about one-third of the town's refuse, and the gas resulting is being used for raising steam in a Lancashire boiler. At Burnley the Corporation's electricity generating station is adjacent to the destructor station, and consideration is being given to the production of electrical energy by gas engines supplied with gas from the Whitfield plant subject to the permission of the Electricity Commissioners and the Ministry of Health.

The Whitfield producer, of which we give a sectional illustration in Fig. 1, embraces new features which have been introduced to obviate the troubles which have been met with in the past in dealing with domestic refuse. One of these troubles is the variability in size, character, and density of the material which makes it difficult to distribute the air for combustion uniformly through the refuse in the combustion zone. This feature results in the air taking the line of least resistance through the fuel bed, developing excessive combustion at this spot and forming a "chimney" in the fuel bed; localising combustion and forming clinker in the body of fuel. Other disadvantages which have been encountered are the raising of the zone of high temperature, the air escaping through which causes the burning of some of the producer gas as formed, giving high CO_2 and low CO contents. In this manner, also, the gas formed is hot and cooling results in thermal losses. Further, tar is more liable to be entrained in the gas leaving the producer at a high temperature, and this fact gives rise to tar troubles.

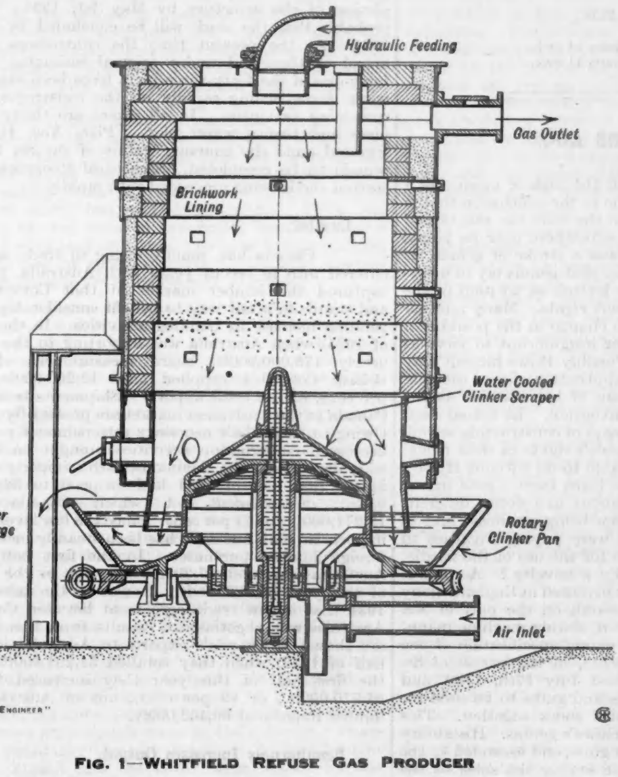

Fig. 1—Whitfield Refuse Gas Producer

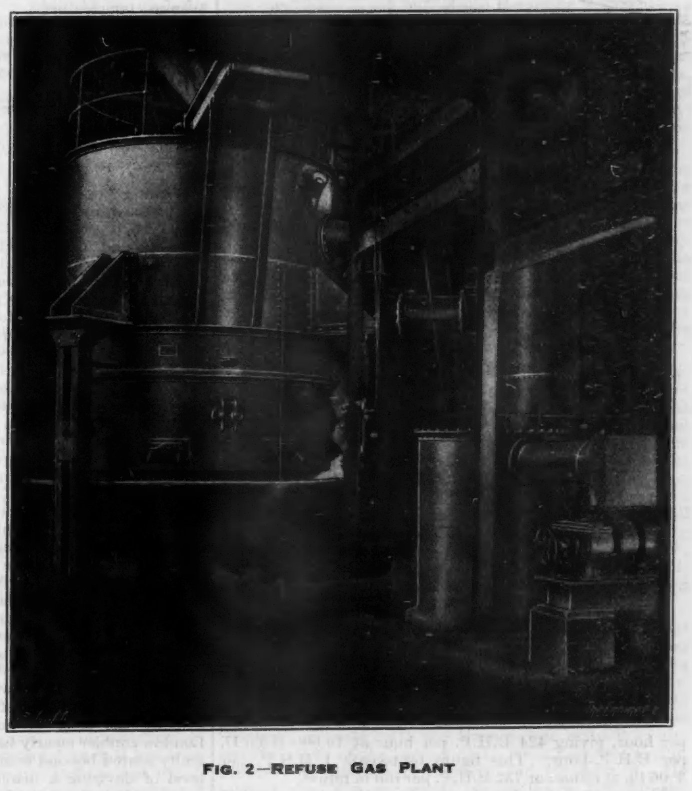

Fig. 2—Refuse Gas Plant

In the Whitfield producer the chief improvement consists in a system wherein the air supplied at low pressure to support combustion is restricted over the whole grate area and meets a uniform resistance in passing through the grate before coming into contact with the bed of fuel. The grate, see Fig. 4, is divided into small sections, and air is distributed over its entire surface, so that each section has an equal amount of air, no matter what may be the condition of the fuel bed above. The grate, as will be gathered from the detail drawing reproduced herewith, is composed of a series of truncated cones of diminishing diameter piled one on top of another. These cones are held together by bolts or studs. On the underside of each pads are formed, the space between these pads constituting expanding orifices from which the air issues. By this means equal distribution of air is claimed to be effected throughout, and no excess air can find its way above the normal combustion zone, thereby restricting combustion to the layer immediately above the grate where the clinker forms and whence it is most easily removed. Another point which the makers claim for this producer is that a reduced depth of fuel bed can be used, and thus less suction or pressure is required, while the confinement of the fuel bed to a low level results in the upper portion of the producer being cooler and giving a lower temperature of gas and in the retention of more tar in the producer, which is condensed in the new fuel on top of the bed. The other important feature is the absence of excess air in the higher parts of the bed, which prevents the burning of the gas in the producer.

As will be observed from the sectional drawing, the conical grate is mounted in the clinker pan, which holds the water seal. The body of the circular generator, which, in the Burnley plant, is 8ft. diameter, terminates below the water level in the pan, and is supported from outside stanchions. The body is water-jacketed to a height immediately above the combustion zone. The pan and grate are caused to revolve slowly by means of a worm reduction gear engaging a large worm wheel attached to the underside of the pan, the speed being variable between one revolution per hour and one revolution in four hours. In the Burnley plant power for this purpose is supplied by a ½ horse-power electric motor. The air which is passed through the grate is provided by a small fan, and is saturated with steam which can be obtained from the water jacket, but which, in the Burnley plant, is supplied from the existing destructor boilers. The refuse is fed into the producer through the hopper at the top by means of a square hydraulic ram, which also acts as a gas seal, and the gas outlet is at the side immediately below the ram feed. The clinker which is formed on the grate is scraped off by means of arms immediately above the grate as the latter revolves, and then passes down into the pan. A plough fixed to a supporting stanchion and carried down into the pan evacuates the clinker as the pan revolves.

The gas, on leaving the producer, passes through primary and secondary coolers, Figs. 2 and 3, to a tar extractor, where the last traces of tar are eliminated. A sample of the gas taken by the Borough Analyst gave the following analysis :—

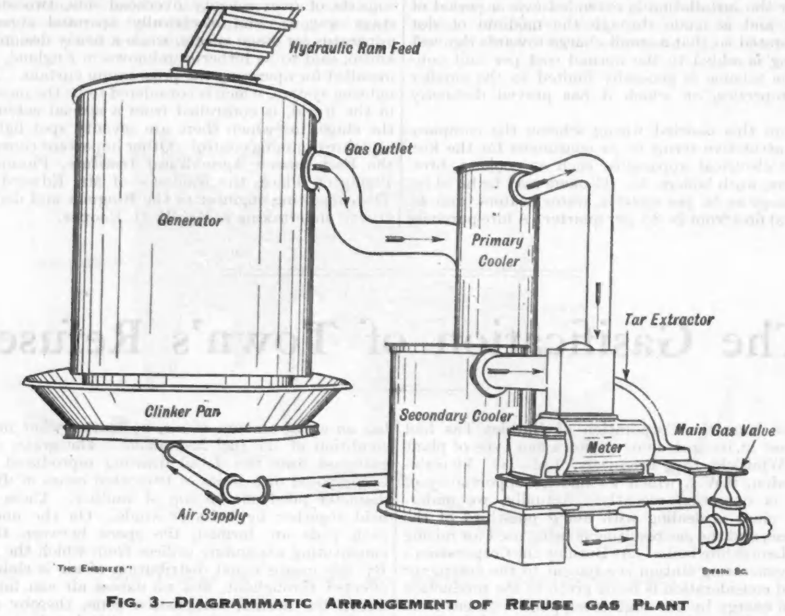

FIG. 3—DIAGRAMMATIC ARRANGEMENT OF REFUSE GAS PLANT

	Per cent. by volume.
Carbon dioxide	10·2
Oxygen	0·4
Nitrogen	48·2
Carbon monoxide and hydrogen	40·0
Hydro-carbons	1·2
Total	100·0

The results of tests carried out by the Burnley Corporation Cleansing Department are given in another table below. The figures show an average gas yield per hour of 32,100 cubic feet from an average feed of 11·6 cwt. per hour, giving 424 B.H.P. per hour at 10,000 B.Th.U. per B.H.P.-hour. This figure represents 1 B.H.P. per 3·06 lb. of refuse, or 732 B.H.P. per ton of refuse.

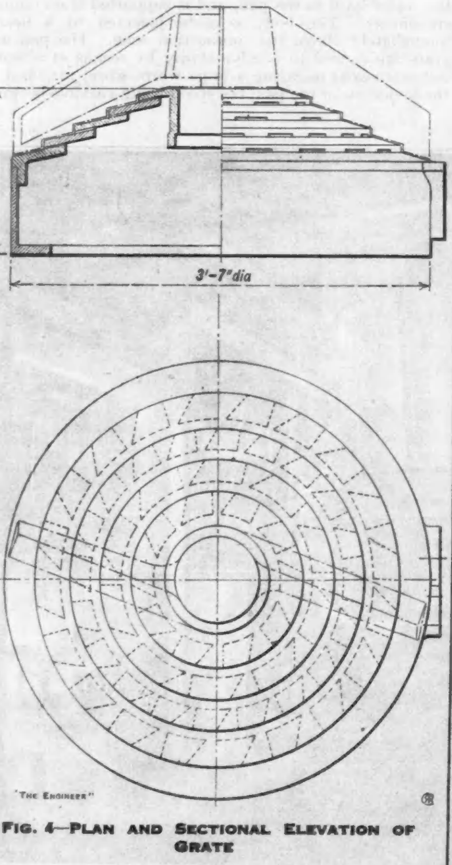

FIG. 4—PLAN AND SECTIONAL ELEVATION OF GRATE

The report states that the quality of the screened refuse was very poor, as it contained a large amount of paper. It also states that the dust had been removed by passing the refuse through a screen of ⅜in. mesh and that the refuse was fed into the generator by hand.

Mr. Arthur Race, the Borough Engineer and Surveyor, estimates that a plant of this description large enough to deal with the whole of the refuse of Burnley would cost £34,000, and would cost the Corporation £6277 annually for interest, working cost, maintenance, overhead expenses, and the removal of dust and clinkers. Against this he estimates a production of 605,000,000 cubic feet of gas per year, 2,000,000 cubic feet of which would be used for the incineration of offal refuse, leaving 603,000,000 cubic feet of an average calorific value of 125 B.Th.U. per cubic foot. The horse-power-hours available on a basis of 10,000 B.Th.U. per horse-power-hour would be 7,537,500. The units of electricity generated, with a generator efficiency of 90 per cent., would be about 5,000,000 per annum. Assuming that 0·15d. per unit is realised for the gas supplied to the electricity undertaking, the annual revenue would be £3125, and therefore the cost of refuse disposal would be £3152 per annum, or 2s. 10½d. per ton. No allowance has here been made for possible revenue from the clinker or separated dust, metals, &c.

Test Results.

Period of test	Commencing 11 a.m. Monday, June 26th, 1933, continuously until 11 p.m. Friday, June 30th Saturday, July 1st, 8 a.m. to 11 p.m. Monday, July 3rd, 8 a.m. to 11 p.m. Tuesday, July 4th, 7.30 a.m. to 11 p.m. Wednesday, July 5th, 8 a.m. to 11 p.m.
Total weight of refuse dealt with	97 tons 18 cwt. 2 qrs.
Total quantity of gas produced	5,409,900 cubic feet
Total number of hours worked	168¼
Average calorific value of gas (from calorgraph chart)	132·1 B.Th.U. per cubic foot (gross)
Average temperature of gas at outlet ..	85·6 deg. Fah.
Weight of clinker removed from plant ..	Wet—63 tons 14 cwt. Dry—45 tons 11 cwt.

SIXTY YEARS AGO.

When Elias Howe set himself the task of producing a sewing machine he speedily came to the conclusion that it would be necessary to transfer the hole for the thread from the end of the needle to somewhere near its point. This departure from tradition was a stroke of genius, or perhaps it would be better to say that genius lay in incorporating this apparently minor feature as an item in the subsequent application for patent rights. Many another man might have considered the change in the position of the needle eye as too obvious or insignificant to serve as the basis of a specific claim. Possibly Howe himself may have included it in his patent application almost casually and looked upon the mechanism of his machine as the really important part of his invention. In actual fact, however, there were dozens of ways of constructing sewing machines without infringing Howe's rights in their mechanical details, but no one was able to do without Howe's needle. Sixty years ago, as we learn from a note in our issue of October 17th, 1873, about five dozen different varieties of sewing machine were being produced and in every case the manufacturers were paying royalties to the trustees of the Howe estate for the use of the needle. But was the Howe needle really a novelty ? A rumour began to spread that it had been invented in England many years previously. Diligent research on the part of Mr. Lucius Lyon, of Finkle and Lyon, sewing machine manufacturers, brought to light the patent specification of one Thomas Saint, of Greenhill Rents, in the parish of St. Stephen, London. It was dated July 17th, 1790, and covered a composition of resins and gums to be used for sticking the soles of boots and shoes together. This London cobbler clearly lacked Howe's genius. His ability really soared beyond resins and gums and ascended to the level of devising a machine for sewing the soles to the uppers. It had a spool for the thread, an awl to make the holes in the material, and a needle to drive the thread through the hole, and the eye of this needle was at the point precisely as in the Howe machine. A drawing of the machine—and for that matter a drawing of a weaving machine and several other appliances—accompanied Saint's specification of 1790, but the textual portion was devoted entirely to the resin and gum compound. Not a word was said about the machinery illustrated by the drawings. Hopes were at once raised by the discovery of this old specification. Some held that it would put an end to the payment of royalties to the Howe estate. Others went further and talked about recovering the enormous sums which had been paid in past years by way of royalty. We ourselves took the trouble to examine Saint's specification. We found it to contain "a most unintelligible drawing" of a sewing machine of apparently the crotchet stitch type. Our American friends could rest assured, we added, that even if Howe's patent were proved to be invalid it would be impossible to recover the royalties already paid to Howe and his trustees.

Canadian Engineering News.

(By our Canadian Correspondent.)

British Exhibits in Canada.

As a medium for the development of trade between the various countries of the British Commonwealth of Nations, the work carried on by the Federation of British Industries in enlarging and strengthening the trade ties of Empire, was well illustrated in its exhibit at Canada's annual National Exhibition, at Toronto. The recent display marked the tenth anniversary of the Federation's first appearance in Toronto. Starting as quite a small affair of about twenty exhibitors in 1923, it has grown until it now comprises some fifty exhibits covering between twenty and thirty different industries. At the recent Exhibition the Federation's exhibit of British manufactures occupied nearly the whole of the north and south wings of what is known as the old Government Building, covering an area of 17,000 square feet. Of all the British exhibits there was one that calls for special mention—the motor truck travelling exhibit of Sir W. G. Armstrong, Whitworth and Co., Ltd. The company's truck contained a complete collection of pneumatic tools sent to Canada in furtherance of the company's policy to make a special effort to increase its trade with the Dominion. The samples shown at Toronto were chosen with a view to their suitability for North American requirements, just as the five similar motor trucks now touring elsewhere carry tools applicable to local requirements. One of the great advantages of the work of the Federation of British Industries in staging an annual exhibit at Toronto lies in the assistance it gives to British firms new to Canadian markets. The last ten years have proved that for newcomers an exhibit at Toronto saves a great amount of exploration work. By arranging test displays they are able to ascertain the reaction of the Canadian people to various classes of goods and can judge in the quickest possible time how acceptable, or otherwise, their products may be to Canadian buyers. Another important feature of the British display is the private view each year held on the afternoon before the public opening of the Exhibition. This has become an occasion of some consequence in Toronto, and is attended by upwards of 2000 guests, all of whom are directly interested from a commercial point of view in the various goods displayed.

Progress of St. Lawrence Bridge.

The 3,000,000-dollar bridge spanning the St. Lawrence River between Caughnawaga and Ville La Salle, which is being erected by the Lake St. Louis Bridge Corporation, will, in all probability, be completed approximately a year ahead of schedule. Plans called for completion of the structure by May 1st, 1935; but it is probable that the work will be concluded by July 1st, 1934. At the present time the contractors are both ahead of time and under original estimates. Already forty-one of the forty-three piers have been erected, and work is proceeding rapidly on the construction of the remaining two piers. In all, there are thirty-one land piers and twelve water piers. Piers Nos. 11 and 12, situated amid the coursing waters of the St. Lawrence, remain to be completed. Structural steelwork has also started and is being proceeded with rapidly.

Lumber.

Canada has, mainly owing to trade agreements entered into in recent years with Australia, practically captured the lumber market of that Commonwealth, and stands in a fair way to benefit considerably from the pending increase in building activities. In the first half of 1925, when Australia was importing to the extent of nearly 173,000,000ft. board measurement of lumber, British Columbia supplied only 12,200,000ft., or 7·6 per cent. of the total imports. Shipments from Eastern Canada to the Australian market are practically negligible. Owing to Australia's necessary retrenchment policies and decreased construction activities brought on by world-wide depression, the Commonwealth's imports of lumber in the first half of 1931 had dropped to 32,320,000ft. board measurement, of which Canada supplied 13,271,000ft., or 41 per cent. Since the low level of lumber imports in 1931 Australia has been steadily increasing her foreign lumber purchases. In the first half of 1932, Australia imported 57,398,000ft., and in the first half of this year 69,402,000ft. It was in the latter part of 1931 that a new trade agreement between Canada and Australia was negotiated. Results from this agreement are shown in Canada's exports to Australia in the first half of 1932, when they totalled 51,291,000ft., and for the first half of this year they increased further to 64,770,000ft., or 88 per cent., out of Australia's total lumber imports of 69,402,000ft.

Beauharnois Increases Output.

The power output of the Beauharnois Power Corporation has been increased from 60,000 to 133,000 H.P. Of this additional power the Ontario Hydro-Electric Power Commission has taken 40,000 H.P., and the Montreal Light, Heat and Power Consolidated 25,000 H.P. The balance of 8000 H.P. is taken by Montreal Cottons. The company's contracts call for the eventual delivery of 462,000 H.P.

Railway and Road Matters.

The tessellated pavement, now known as the Checkon Pedestrian Safety Crossing, mentioned herein on August 18th as having first been used in Salford, is being laid down in Leytonstone, Croydon, and Brixton.

Some 15,000 employees of the L.M.S. Railway will be attending special classes and lecture courses this winter in accordance with the company's policy of providing free educational facilities for many grades of its staff.

The "Royal Scot," the L.M.S. Railway's complete express train which is now on exhibition at the Century of Progress Exhibition at Chicago, is to make a further extended tour of Canada and the United States during the autumn.

The Railway Operating Medal and the Railway Engineering Medal, given by the Railway Companies' Association for inclusion in the awards made by the Institute of Transport, have been won by Mr. E. D. Grasett and Mr. F. Lydall respectively. The paper read by the former was on "Freight Train Operation," whilst Mr. Lydall dealt with British Main Line Electrification. The medals were presented by the President, Mr. W. Whitelaw, at the opening meeting on Monday, October 9th.

The worst train accident on the railways of Ireland was the Armagh disaster of June 12th, 1889, when eighty passengers were killed. The next most serious accident in Ireland occurred eighty years ago. It occurred at Straffan, Great Southern and Western Railway, on October 5th, 1853, and was due to a collision between a passenger train and one conveying cattle. Fifteen passengers were killed, and it was the most serious accident on the railways of the United Kingdom up to that time, and remained so until the collision of August 25th, 1861, in Clayton Tunnel, when twenty-three passengers lost their lives.

The publication of an agreement made between the railway companies and the proprietors of privately owned rolling stock as to the charge for the transit of their empty wagons, shows that there are 526,000 such wagons. Of these, 373,000 belong to collieries, coal merchants, coal factors, &c.; 125,000 mineral wagons, and 500 tank wagons are the property of wagon-hiring companies; 16,000 are used for ironstone, gravel, brick, lime, cement, &c.; and 11,500 are tank wagons owned by oil companies. The agreement in question is the result of prolonged discussions between the companies and a committee of traders as to the interpretation to be put upon the entry in the General Classification as to rolling stock regulations. Instead of paying separate charges for individual wagons, the traders are to make a collective payment of £21,000 a year; originally, the railway companies estimated their gross annual receipts from charges paid for the haulage of empty privately owned wagons to be upwards of £37,500.

The Raynes Park, Southern Railway, derailment, and the subsequent collision with the derailed coaches, of May 25th, when five passengers were killed by the collision, has revealed a weakness in the railway companies' standard rules as to engineering work that affect the safety of the track. It may be remembered that as a passenger train was running between Wimbledon and Raynes Park on the down through line the engine and its five eight-wheeled vehicles were derailed. Some of the coaches fouled the adjoining up through line and were struck by an up passenger train. As part of a programme of improvements the long curve that begins at Wimbledon was having its radius at this point increased from a minimum of 64 chains to one of 80 chains. That was done on the preceding week-end, and the work in hand at the time of derailment was "to top and fettle the high rail of the curve, and to correct the superelevation where necessary." That had to be done between trains, and, when the down train approached, a lift of at least 1¾in., and possibly more, was in hand, but the time available proved insufficient to pack all the eleven or twelve sleepers, and the track was thus temporarily defective. Colonel Anderson concludes his report on this accident by saying that it illustrates the need for the greatest caution when any such work on the track is carried out under fast and dense traffic. While the height of a lift has hitherto apparently been taken as a criterion of what may or may not be done without possession of the line or speed restriction, the time interval between trains appears to be equally important.

The fatal collision of June 17th between a double-headed express and a mineral train at Crich Junction, Ambergate, London, Midland and Scottish Railway, mentioned herein on June 23rd, was inquired into by Colonel Trench, whose report was issued on October 5th. As both drivers were killed and their firemen were unable to throw any light on the condition of the signals, there is only the evidence of the signalman concerned to support the conclusion that the express ignored the distant, inner home, and starting signals at Wingfield. All the facts, moreover, point to that having been done, and it thus becomes a question as to how such men, of whom it is said that they "had good records and were considered sound passenger express drivers," came to be so remiss in their duty. In this connection we would refer to a paragraph which appeared in this column on September 1st last, wherein we suggested that the driver who was found responsible for the Ais Gill collision was misled by the signalman not fully acting up to a rule which provides that when a starting signal is at "danger," the home signal must be kept "on" until the train has been brought quite, or nearly, to a stand. At Wingfield, as at Ais Gill, the home signal was put to "clear" prematurely, and the drivers would therefore naturally assume that the other stop signals were in their favour. There is also the possibility that the distant at Wingfield might have been missed and the home signal taken for the distant. Colonel Trench recommends therefore that if the companies cannot see their way to delete the words "or nearly," they should see that the "nearly to a stand" should be rigidly obeyed. He points out that the accident was one which would have been prevented by automatic train control, and that it showed the value of the detonator placers which were now being provided in new and reconstructed signalling installations.

Notes and Memoranda.

The imports of electrical machinery, apparatus, and cognate material into Italy during the five months ended with May last attained a value of £663,365, as compared with £929,110 in the corresponding five months of 1932. There was also a decline during the same period in the exports of similar material from Italy from £768,730 to £294,540.

The uses of tin are analysed in a survey prepared by the International Tin Research and Development Council in London. Amongst the uses mentioned are those connected with the electrical industry, such as the manufacture of wires, wireless parts, lighting fixtures, refrigerator coils, solders, cable sheathing, lampshades, &c., and (in the form of tinfoil) in electrical condensers.

The Soviet stratosphere balloon, the "U.S.S.R.," made a second ascent into the air on Saturday, September 30th, and reached an altitude of nearly 12 miles. The balloon was in the air for 8 h. 15 min., and important scientific observations were made. According to later reports, it is now believed to have gone higher than the 12 miles originally recorded on Saturday. A special commission of scientists is checking the instruments and calculating the maximum height from data taken at land observation points. Meanwhile, the possibility of making further flights throughout the winter months is being discussed.

It is with regret that we have to record the death on Tuesday, October 10th, of Mr. Joseph P. Wolfe, formerly the chief engineer of the White Star liner "Majestic." Mr. Wolfe was born in Liverpool and educated in London, where he served his apprenticeship with the Thames Ironworks, and afterwards with Laird Brothers, of Birkenhead. He began his sea-going career with Lamport and Holt, Ltd., and transferred to the American Line in 1894, later going to the White Star Line, in which he served as chief engineer in many of the largest liners. At the end of the war Mr. Wolfe was sent by the White Star Line to Germany to superintend the completion of the "Homeric" and "Majestic" prior to these liners being handed over. Later he took over the post of chief engineer of the "Majestic," and remained with her from that time until indisposition caused him to relinquish his post in October, 1930.

The correct way to fit a stud depends, says Mr. E. S. T. Hill, in the *American Machinist*, on what the stud has to do. A parallel thread may not hold unless bottomed. It can only be made to hold by deforming the threads. It seems better not to bottom, but to deform the unthreaded portion of the stud. Hence it is wrong to make the stud with a collar strong enough to allow thread deformation. If the stud is not asked to stand a big stress, use parallel threads, tight if desired, but do not deform them. Obviously, it is waste to make a screw and then to destroy it. For heavy duty, a taper thread is to be preferred, as it enables a real jamb to be effected without spoiling the screw. But in most of the instances where studs are used the duty is heavy and a stud is not good practice. It is doubtful whether a machine exists after a few years of use in which the studs have not given trouble to the millwright. Bolts, rivets, and pins are often better engineering and better for the repairer.

The lithopone manufacturing industry was founded and first developed in this country by Mr. John Bryson Orr, who recently died at the age of ninety-four. He lived long enough to see, under the stimulus of the new fiscal policy, a marked revival in the manufacturing industry. Despite the introduction of newer white pigments, lithopone seems destined to maintain its position in the paint, rubber, linoleum, and other industries. The reaction whereby a pigment consisting of barium sulphate combined with zinc sulphide is produced by the double decomposition of solutions of zinc sulphate and barium sulphide has been described as one of the most remarkable reactions in industrial chemistry. Orr's invention, whereby the pigmentary properties are developed by igniting the precipitate to redness in the absence of air, discharging the red-hot mass into cold water and thoroughly grinding whilst wet, laid the real foundations of the modern lithopone industry.

An interim report of the Inter-Departmental Home-grown Timber Committee, 1933, issued by the Stationery Office, contains short references to the use of larch, Scots pine and other timbers for power transmission line, telegraph and telephone poles. As a result of evidence given by the Electricity Commission, Central Electricity Board, and Overhead Lines Association, the B.S.I. has under consideration a specification for larch poles for use in transmission lines. The Institution is collecting cost data and going into the economics of the matter; the Forests Products Research Laboratory is testing for strength and securing evidence of durability. Home-grown Scots pine poles of a minimum size of 16ft. long and 6in. in diameter at the butt are accepted for telephone poles by the Post Office. At the request of the Committee, the Forests Products Research Laboratory is testing Corsican pine, Norway spruce and Sitka spruce for strength and capacity for absorption of preservatives. If the tests show that these timbers compare favourably with Scots pine, the Post Office will give them an endurance test.

The use of super-hard materials for tipping tools has, says *Machinery*, increased, for the advantages resulting from their employment in various machining operations has been abundantly demonstrated. Many of them consist essentially of tungsten carbides bonded with or alloyed with different metals. Some of them are produced by sintering powders and others are melted and cast. The application of these materials has been successfully extended in many cases to the manufacture of drawing dies and many alloys are marketed under various trade names. One of the most recent developments in the field has been the production of cemented tantalum carbide dies which are claimed to compare very favourably with cemented tungsten carbide under similar conditions of test. A method has been perfected in America of mounting tantalum carbide tips by brazing an inset of pure molybdenum between it and the steel shank. Since molybdenum has almost the same coefficient of thermal expansion as tantalum carbide alloys, its use prevents strains being set up or cracks developing in the tips after brazing.

Miscellanea.

The zinc oxide plant of the Sulphide Corporation at Seaton Carew is being extended on account of the increased demand, both at home and abroad.

It is said that an ample supply of potable water for Rangoon has been discovered, and that the cost of its development will not be prohibitive.

The high-level sluices of the Mettur dam, in Southern India, were opened for the first time about the middle of September and the water turned into the canals.

It has been found necessary to postpone the reception by the President of the Institution of Chemical Engineers from November 16th to Wednesday, November 22nd.

The United Provinces of India Government proposes to organise a scheme for the production of motor spirit from alcohol with the idea of stabilising the sugar industry.

Owing to prevailing trade conditions, the Textile Machinery and Accessories Exhibition, which was to have been held in Bradford, Yorkshire, from October 11th to 21st, has been indefinitely postponed.

It appears that the consumption of electricity in the area of the West Midlands Joint Electricity Authority has increased by 11·3 per cent. during the last six months. The greatest rate of increase has come from industrial centres.

The Cardiff Waterworks Committee has decided to expend £40,000 in developing a water supply from the lower catchment area at Llwyn-on, in the Brecon Beacons, which will give the city an additional daily supply of 4,000,000 gallons.

On Saturday, September 30th last, an interesting event took place in the social life of the works of Thompson Bros. (Bilston), Ltd., in the form of the opening of the company's new recreation ground for employees, by the Charter Mayor of Bilston, Councillor H. Beach, J.P.

Among the proposals of the Dutch Government for the relief of unemployment is one which suggests the improvement of the Merwede canal connecting Amsterdam and the Rhine. The scheme will cost about one-third of a million sterling and involves a canal with a width of 164ft. and only one lock.

Nearly 200ft. of dyke protecting the north coast of the Island of Beveland, on the Eastern Scheldt, about 20 miles north-east of Flushing, suddenly sank on Wednesday to below the normal level of the land. The breakdown exposed the fruit farms in the neighbourhood to flooding with the rise of the tide, and it is feared that very great damage may be caused to orchards near the shore. Fortunately, the danger is considerably reduced by the fact that a second or inner dyke stands about 50 yards inland.

The question of utilising the sun's energy has in recent years been attracting the attention of scientists and engineers. Now we learn that a Russian has invented a solar kitchen. It has been constructed by Mr. Poshtar, a member of the helio station in Samarkand. He recently tested his apparatus in the presence of scientists and technicians and representatives of Soviet public life, and the *Pravda Vostoka* reports that meat soup was cooked on the solar kitchen range in two hours, and that kashba (a kind of porridge made of buckwheat) with meat took fifty minutes to cook.

Since the Royal Charter was granted to the Institute of Marine Engineers in March last an important alteration has been made in the regulations governing the admission of students. A detailed syllabus of the student examination has been issued, with particulars of exemptions open to candidates possessing certain educational qualifications. The next examination will be held in May, 1934, at various centres, according to the candidates' places of residence. Full particulars may be obtained on application to the Secretary, the Institute of Marine Engineers, The Minories, London, E.C.3.

It is understood, says the *Iron and Coal Trades Review*, that, in connection with the scheme for establishing a coal-distillation factory near Irvine, Ayrshire, a new company is being formed, to be known as Charles Turner (Scotland), with a capital of £1,000,000. The company is to acquire from the vendor, Turner Trust, Ltd., the sole and exclusive licence to use the Turner patent and process in Scotland. In order to ensure adequate supplies of suitable coal the company propose to acquire two collieries—the Mauchline colliery in Ayrshire, and the Auchlochan colliery in Lanarkshire.

On Wednesday, October 4th, the Hon. Oliver Stanley, the Minister of Transport, in company with Members of Parliament, inspected the million-pound improvement scheme now being carried out by the Grand Union Canal Company. When the work is finished, along the whole of the route from London to Birmingham canal banks will have been concreted; canal locks will have been widened from 7ft. to 12ft. 6in.; loads up to 100 tons will have been made possible; and horse-drawn boats will be largely replaced by motor-driven models. Over fifty new locks are being built during the course of the work, many of them by the side of others over 100 years old. A feature of the scheme is that not once has it been necessary to suspend the through traffic.

At a conference held at Buckie on Saturday, September 30th, it was stated that in 1924 the Buckie Fleet comprised 285 steam drifters. This was reduced to 241 five years later, and the number was becoming less every year. Seventy per cent. of the drifters were over twenty-five years old. Sir Godfrey Collins, the Secretary of State for Scotland, in reply, said the Government realised to the full the plight of the herring fleet. That fleet was a vital necessity to the fishing industry and for defence. He realised that the arguments placed before him for the modernising of the herring fleet deserved the most careful consideration. He could assure them that the matter would be looked into. Sir Godfrey afterwards inspected a large motor-drifter under construction in the building yard of Messrs. Thomson and Stewart, Buckie, a type which is expected to prove the successor of the steam drifter.

A RAILWAY CHAIRMAN'S ADDRESS.

The new President of the Institute of Transport is Mr. William Whitelaw, the Chairman, since its constitution in 1922, of the London and North-Eastern Railway and previously the chairman of the then North British and, earlier still, of the Highland. In the inaugural address which he delivered on Monday evening last, Mr. Whitelaw mentioned, in his opening remarks, that he had been a director for thirty-five years, during thirty-two of which he had borne the responsibility of the chairmanship. Such a lengthy service in so high an office might give to those who do not know him a wrong impression of Mr. Whitelaw's age, but we can assure them that, when, in relating an event in the year 1901, he speaks of himself as "a young enthusiast," he was aptly describing himself as he was at that period. We may add that, though he is now more than thirty years older, he still retains his former enthusiasm. In that year, as he recalled in his address, he proposed the acquisition of the Highland Railway by the Caledonian and the London and North-Western. He told the late Mr. C. H. Mason, the solicitor to the latter company, that the Highland would soon be earning a dividend on its ordinary stock. Mr. Mason replied that if he was convinced that even 1 per cent. could be earned, he would advise his board in favour of amalgamation, but he added, in the most kindly way, that, while he did not wish to damp the ardour of a young enthusiast, he could not believe that any such dividend could be earned by the Highland. That ended the proposal, but Mr. Whitelaw's prophecy came true; in 1903 the dividend of 1 per cent. was earned and paid, rising gradually to 2½ per cent. in 1913. Had the Highland been absorbed the East Coast companies would doubtless have proposed to purchase the Great North of Scotland Railway and thus a part of the existing amalgamation might have been carried out twenty years before it was accomplished under the Act of 1921, and there would have been none of the controversy, raised by the proposals of Sir Eric Geddes, as to whether the Scottish companies should be united in one group or, as was done, combined with their English allies in parallel lines.

We mention this anecdote as illustrating the ability of the new President to speak, from experience, to the young men of the Institute and particularly to the railway operating men. There is a considerable amount of candour in what he says. His remarks on examinations and their value, particularly his playful suggestion that "fail-ees" should be allowed to set examinations for the examiners, will appeal to many young engineers. Elsewhere he remarks that railway managers engaged in the practical management of their companies would have an easier life "if they were able at times to disregard the theories of the engineer, the kindly autocracy of the accountant, and the restriction imposed by the legal adviser." Mr. Whitelaw then tells a good story of how six-coupled engines were not allowed north of Inverness because their axle load was beyond the limit laid down for that territory. Subsequently it was found that the drivers of the engines in common use had been in the habit of adjusting the axle load so that the weight borne exceeded the limit which the engineer considered was the maximum! Fortunately they did not damage the line. The fallacy of depending upon theory instead of on fact was exposed by an illustration from the amount of track renewed each year on the Highland. Between 1902 and 1909 the average renewal was 10 miles a year, but between 1909 and 1913 it was only about 4 miles a year. Engineers, generally, would not expect such a permanent way to be in very good order, but the war brought a traffic which every month of four years was far in excess of the amount carried in the busiest month of the summer of previous years. Obviously the condition of the permanent way was put to an extremely practical test. Moreover, the line north of Inverness was intended only for the light rolling stock used there, but during the war it had to carry, daily in both directions, the heaviest passenger rolling stock of the London and North-Western Railway. The Highland ceased to have a separate existence in 1923, before which date, with an average renewal of only about 7 miles a year out of a total track mileage of 564, the permanent way should, according to generally accepted theories, have ceased to function. Mr. Whitelaw does not suggest that such a programme of renewal could be applied to railways generally, but the facts just related at least "cause one to think that such a practical test of the endurance of the permanent way is not without its lesson." The question is then asked: Have permanent way engineers made sufficient allowance in estimating the life of their roads for the greater weight of rails and chairs, better fastenings, more efficient creosoting of sleepers, more attention to good drainage, and the greatly extended use of stone ballast in place of gravel or ash? Have they made any allowance for the wonderful improvement in the balancing of locomotives, so that a locomotive weighing 120 tons or more may be much lighter on the road than one of older construction weighing much less? The same thing applies to bridges; "only a few years ago engineers had to condemn girder bridges on mathematics, where to-day their strength can accurately be measured, and fact, by displacing pure theory, has added years of life to many a railway bridge." Mr. Whitelaw daringly suggests that it is possible that, in the past, unnecessary expenditure has been incurred on renewal of the permanent way because its life was estimated wholly upon theory, and that actual inspection and practical testing thereof, to secure reliable facts as to its condition, may well lead to definite savings in that branch of railway expenditure. He does not think too much importance can be attached to the day-to-day maintenance work on a line, and he feels sure that the efficient performance of that work would add very materially to the life of a well-laid road.

The latter part of the address deals mainly with the Railways Act. The principal theory of the Act was that an economic basis for the amalgamated companies would be found by stating the remuneration to which the owners of railway capital should be entitled; and by the appointment of one tribunal to fix wages and conditions of labour, and another to ascertain and fix rates and fares which would, under efficient management, provide the cost of labour and the proper remuneration of capital. "The latter tribunal has, year by year, given the companies its certificate of efficient and economical management, but has found its duty of fixing rates and fares for the proper remuneration of capital, in the face of the cost of labour as fixed by the sister tribunal, to be impossible of discharge. The Act had assumed that there would always be traffic awaiting conveyance at the necessary rates and fares, and Parliament does not seem to have given any consideration to the situation which has actually arisen, in which the traders are clamouring for lower rates and greater rapidity in conveyance, while, even at the existing rates, the economic position aimed at has not nearly been reached. Here, certainly, is an instance of the breakdown of theory before irrefutable facts." In drawing attention to what Mr. Whitelaw has to say about wide decentralisation we recall the objection we raised when grouping was being proposed a dozen or more years ago. We then said that it was out of the question that the authorities at Euston could have the same close acquaintance with local conditions in the Potteries that the North Stafford Railway people had, or that they would have the same knowledge of hematite ore that the Furness Company possessed. Mr. Whitelaw, on the present occasion, says that, even in this small island of ours, there are many important centres of commercial enterprise and, between the North of Scotland and London, railway problems are by no means always similar nor are the requirements of traders always identical. But whatever their differences, there is one thing all traders are unanimous about, and that is that they should be able without undue exertion and difficulty to meet with a man in real authority who has power to come to a definite arrangement in connection with their transport problems, without reference to a head office, situated, it may be, some hundreds of miles away. "The spreading of the responsibility," he says, "becomes more and more necessary as the task increases in volume and complexity, but with adequate decentralisation there seems to be hardly any limit to the size of a company which can be put under one control; it is all a mixture of personal control and wide diffusion of responsibility throughout the geographical area served by the company." He, for one, would have no fear of the unification of all the railways. "Probably it will be said that that would be just the penultimate step to nationalisation. The statesmen of the future will be well advised not to be frightened by a name. National management of the railways would prove," he is satisfied, "ruinous to both passenger and industrial transport, but national ownership, with management completely divorced from political influence, is not impossible and cannot be dismissed from consideration for all time because of the prejudice attached to the name of nationalisation."

On another page we reprint the major part of the address and we feel sure that many engineers will read it with the greatest pleasure. The public, as we know, is all too prone to forget the benefits which the railways confer, and to censure them for defects which are often outside their control. It is of interest now and then to see the railways from a chairman's point of view, and when that chairman has the long experience enjoyed by Mr. Whitelaw and a facility for coming lightly, but directly, to the point he desires to make, his comments are likely to be remembered. To some of his views we have alluded above. Not all of them will be readily accepted, and concerning two, at least, there will be strong differences of opinion—we refer to his remarks on permanent way and nationalisation. If there is one thing more than another of which British railways can justly boast, it is the upkeep of the permanent way, in which we include bridges. Engineers, we believe, have not, in fact, been slow to appreciate the good effect of the reduction of locomotive hammer blow, but it will take a deal of persuasion to induce them to go below the factors of safety which have become traditional. Often it is good economy to be too strong than even a little too weak. On the question of nationalisation we can only say here that if the word has become ominous it is because a certain school of thought has made it so. Probably the railways themselves would have no objection to nationalisation—for a due consideration—but it will always be opposed by those who fear that it would be but one more step towards the nationalisation of everything and the supersession of the individual.

Waste.

Under the heading "Waste in Manufacture," we gave, in our last issue, a few extracts from the Presidential Address which Mr. Engelbach delivered to the Institution of Automobile Engineers in London. No one who reads it can fail to be struck by the remarkable figures, taken from the records of a great motor-manufacturing firm, which it presents. It is recognised that the methods employed in the making of cars are the most advanced to be found in the whole realm of mechanical engineering. Yet a leader of the industry was able to show that out of all the materials used only 26 per cent. by weight was to be found in the finished product. Whilst in the case of paint, of which part is admittedly volatile, no more than 2 lb. weight out of the 22 lb. consumed is left on each car body. It might be assumed that in motor car factories at least there was little or no waste beyond that which was inevitable, but Mr. Engelbach told his audience that he himself was so appalled by the figures when he came to collect them for the preparation of his address that he caused investigations to be made, and that they had resulted in considerable reductions.

Whilst the figures put forward by Mr. Engelbach must inevitably cause not only heart searchings, but searchings of a material kind in manufacturing works, and whilst we anticipate that they will increase the acceleration of the engineer's never-ending pursuit for greater efficiency, we fear that in the hands of the partly informed an unjust whip may be made of them for the chastisement of manufacturers. All is not waste that so appears. When Mr. Engelbach states that "in order to produce 170 tons of finished castings 1000 tons of iron ore, 600 tons of coal, and 200 tons of limestone, a total of 1800 tons, have been used," he presents a case which is only appalling because it omits certain facts. The thousand tons of ironstone may contain less than 25 per cent. of iron; but the 600 tons of coal and the 200 tons of limestone have to operate on almost the whole bulk of the ore in the smelting furnace. If Providence had presented man with sufficient meteoric iron to meet all his needs, the expenditure of fuel and flux on the smelting operation would be reduced to negligible proportions. We may perhaps compare the waste that goes on in the production of pig iron, and in many other operations, to the waste of heat in a steam engine. As long as the efficiency of the latter was measured only by Carnot's Law, it appeared to be appallingly low, but when Rankine made the necessary correction for the conditions which obtain in a practicably operatable steam engine, engineers found reason for greater satisfaction. In the same way when the air standard is employed as a basis for the estimation of the efficiency of internal combustion engines, it is seen that instead of being very wasteful, they, in fact, are approaching the limits attainable under the conditions in which they operate. It is undesirable to press this comparison far; the point is that some unprofitable expenditure of energy is inevitable in all conversion processes, and that it is not quite fair to call it "waste" without differentiating between what could be avoided and what cannot. When, therefore, Mr. Engelbach speaks of the "appalling waste that occurs in the materials we use in the production of a car," he may give a wrong impression, unless it is clearly understood that "waste" is the difference between the actual expenditure of energy or materials and the least expenditure attainable under practical conditions and needs. For example, a great deal of the "waste" which occurs from the machining of castings is avoided in agricultural machinery by leaving them rough. But rightly regarded, it would not be waste if the purchaser preferred machined parts. Again, the form of body desired by the car purchaser involves the use of profiled sheets and the waste that results is considerable. It is, of course, possible to conceive a body design in which plain rectangular sheets alone were used and the "waste" reduced to very small proportions. But it would not be acceptable to the user. In other words, the user, in such cases, is more responsible than the engineer for the waste that occurs.

Whilst we advance these arguments to show that waste may not be as appalling as it seems when baldly presented, we are not attempting to undermine Mr. Engelbach's contention that a great deal of it is avoidable. Indeed, we might invite him to add to his study an examination of the waste involved in modern systems of office management, which in many cases cost too much for the efficiency they attain. It is the engineer's constant endeavour to reduce waste, and we have little doubt that Mr. Engelbach's address will have fruitful results. But, before we leave the subject, let us at least recall that if waste is one man's poison, it is another man's meat. By just so much as the motor car industry gains through the reduction of waste, the industries which supply the wasted material must lose. It takes 22 lb. of paint materials to apply 2 lb. of paint to the body of a car. If the waste is reduced by half, the paintmakers will suffer a reduction of output of 50 per cent. Hence, examined from the national point of view, it would appear that the reduction of waste in many—not all—cases can only be justified if it increases the demand for the products on which the saving is effected. That is an interesting economic reflection which we may leave to our readers. A few years ago it would not have called for much reflection; but nowadays, when it appears to be commonly held that the chief "industry" of every factory is the giving of employment, it wears a different aspect.

Co-operation in Science.

By S. C. BRADFORD, D.Sc.

THE early stages of specialisation of which Pope wrote, "One science only will one genius fit," have given place long since to concentration of individual genius within the narrowest subdivisions of special sciences. And now, with deeper knowledge, has come the realisation of the essential unity of all science. The barriers between the old departments of science are broken down and progress in one field may be felt in any other.

Thus the need for co-operation between the workers in all domains is recognised. Means of co-operation are being suggested, of which the bibliographical is the most fundamental. For before recorded information can be explained, or utilised, it must be located.

Few of those engaged upon the production of new scientific and technical data realise the enormous waste of energy in this process which is taking place. Two-thirds of the facts discovered are published, only to be buried in those cemeteries of books termed libraries. Some three-quarters of a million scientific and technical papers are issued every year. The same number of abstracts, or index references, are made in three hundred abstracting or indexing journals throughout the world. Yet only about one-quarter of a million papers are indexed or abstracted in published bibliographies, although it is evident that, without additional expenditure of energy, a complete index to scientific and technical literature could be realised forthwith.

The accomplishment of such an index requires the unification of existing bibliographies by the adoption of a standard system, whereby each fact is indexed, not in regard to a special science, but from the point of view of all science.

Before proceeding to the discussion of such a scheme some new data, which are essential to the proper understanding of the problem, must be recorded. Statistical analysis shows that the literature of a special subject is not confined to a comparatively small range of periodicals purporting to cater for that subject, or for the larger subject of which it forms a part. Such journals contain only a quarter or, at most, a third of the information in question. Papers on a given subject are distributed in such a way that the same number of papers will be found in three or more groups of periodicals, the numbers of journals in which are related as $1 : n : n^2$. Thus, in the subject of lubrication about a hundred papers a year are contained in a nucleus of some twenty periodicals. Another hundred papers occur in a larger group of about one hundred and twenty periodicals, in which each journal includes, on an average, about one paper on lubrication in a year. Outside this group there is a still larger group of about seven hundred periodicals, which contain another hundred papers on this subject at the rate of about one in ten years. Beyond this there are certainly other papers, which appear at rare intervals in a mass of periodicals.

The reason for the present failure of abstracting services now appears. To index the complete literature of a particular subject as it appears would need the weekly or monthly scrutiny of some thousands of periodicals, in the bulk of which relevant articles occur at the rate of from one a year to one in ten years or less. As this is not feasible, only the nucleus of those periodicals specially related to a subject is surveyed, with perhaps a selection of the more important journals in the next group. Thus a third, at most, of the literature of the subject is covered. And this is the extent of the finest bibliographies, as has been amply proved. It is evident that instead of abstracting by subject, periodical literature should be reviewed according to source. That is to say, every important article of each publication should be catalogued irrespective of its subject. If a standard system of classification were employed, as in the case of the International Catalogue of Scientific Literature, the notices, from whatever source, could be amalgamated into one index, or into a series of indexes by subject, where the references would be automatically sorted by the classification, all the entries relating to a particular topic falling together into one place.

It seems that a radical change in present methods of bibliography is needed. The alphabetical system, so much in vogue, is calculated to ensure the maximum of inefficiency and to prevent the possibility of co-operation. The fashion was surely invented by an office boy, who was instructed to index the subjects of his employer's correspondence. As the arrangement is found to scatter information on the same and related subjects throughout the alphabetical jumble, the index is loaded with time-wasting, and necessarily incomplete, series of cross-references, both from synonyms and related topics. Thus the alphabetical index is forced to attempt the reconciliation of the incompatible ideas of classification and alphabetical arrangement.

Those who need to use such compilations for serious work are fully aware of their inconvenience. There are usually half-a-dozen to a score of bibliographies relating to a particular field. At each inquiry each part of each volume of each bibliography must be worked through, piece by piece, every labyrinth of cross-references being followed to its farthest recess. The time expended amounts to hours or even days. And, in the end, there is the uneasy feeling that the indexers have successfully hidden much of the material. Some information officers take the trouble to cut up all the bibliographies they use, mount them on cards, re-head them, and bring them all together into one series, thus anticipating the general solution.

The most serious objection to the alphabetical method is that it necessarily perpetuates the present bibliographical chaos by rendering co-operation impossible. Not only must bibliographies relating to the same subject be kept separate, incomplete as they are, but the references to information on borderline subjects, which would be useful to workers in other fields of science, are hidden from their view. Thus data are indexed by the physicist that would be useful to the physiologist, by the botanist that should be utilised by the agricultural expert, and by the chemist that may be needed by the engineer. These facts remain hidden in their respective bibliographies by the uneconomic system. Yet, as has been seen, the information so hidden may represent the larger part of that upon a particular topic.

The way out of this confusion is obvious. "Let's go hand in hand and not one before another." General agreement to utilise a standard system would yield the desired index forthwith. This idea took shape so long ago as the First International Conference of Bibliography held in Brussels in 1895. The Conference decided that the Dewey Decimal Classification was founded on principles that would enable it to be developed into a satisfactory international bibliographical classification. The International Institute of Bibliography was founded in Brussels by Royal Decree to continue the work of the Conference. From its earliest stages such eminent names as Wilhelm Ostwald and Samuel Scudder were closely associated with the movement. In this country the first publication to adopt the Decimal Classification was "Natural Science," which began in 1896 the addition of decimal numbers to its articles in order "to prepare the way for that bibliographic reform, which all admit to be an urgent need." On the Continent a series of extensive bibliographies was inaugurated. These included, among others, a series of biological bibliographies on cards, the "Bibliographia Physiologica," the "Bibliographia Zoologica," and the "Bibliographia Anatomica," published by the Concilium Bibliographicum at Zurich, with the collaboration of the American Association for the Advancement of Science. Although the "Bibliographia Physiologica" has recently been suspended, the zoological and anatomical portions continue to constitute one of the most valuable bibliographies of any subject ever issued. When the necessary development of the classification had been completed, an extensive engineering bibliography was commenced under the title "Revue de l'Ingénieur et Index Technique." In 1925 this became the "Mededeelingen of the Dutch Institute of Documentation," and, recently, the "Repertorium Technicum."

Bibliographies of various other sciences were commenced, such as the "Bibliographia Geologica" in 1898, and the "Bibliographia Medica Universalis" in 1900. Unfortunately, energy, which might have accrued to the organisation, was diverted into other channels by the creation of a rival system. The Royal Society had taken the lead in bibliographical questions since the publication of its "Catalogue of Scientific Papers" from 1867 onwards. This constituted a list of papers under authors' names. An *index rerum* being needed, another International Conference was held in 1896, which made the fatal mistake of considering the philosophical order of a classification to be more important than its structure. The Conference resolved to set up a new classification, "in which the division of the subject matter in the various branches of science and the nomenclature to be used should be determined by competent bodies." In the result the inflexibility of its nomenclature rendered the classification unsuitable for indexing scientific literature on an international scale. Thus was missed a golden opportunity of establishing an international organisation, which must, almost inevitably, have provided a permanent solution to the bibliographical problem.

In the light of experience it is now easy to perceive another error in the decision of the 1896 Conference.

The error of too great centralisation. The organisation created resembled that corresponding to the higher branches of the animal kingdom in comprising a number of members activated from a single centre. When the central stimuli were inhibited by the World War the whole organism disintegrated. It is necessary to realise that the only control that is needed for the compilation of a World Index is that obtained by the use of a standard classification. The organisation of independent journals using a common classification, originated by the First International Conference of Bibliography, resembled a biological colony whose life is independent of those of its individual units.

In the result, the superiority of the classification and the methods of the International Institute of Bibliography have been demonstrated by its survival and increasing development. Despite the setback experienced in 1896, and the continual lack of even those few funds, which are needed for the proper administration of an international classification, the number, scope, and extent of bibliographies classified by the Decimal Classification have increased.

The Optical Society was the first scientific institution in Great Britain to adopt the Decimal Classification, which it did in 1926. Perhaps the greatest impetus was given to the movement by the foundation of the British Society for International Bibliography in 1927, whose honorary secretary is Mr. E. Lancaster Jones, at the Science Museum. Subsequently the classification was adopted by the Royal Society for the B Section of its "Proceedings," by the Royal Photographic Society, the Physical Society, the Physiological Society, the Imperial Agricultural Bureaux, and many other societies, research associations, and Government institutions, both at home and abroad, until the number of references classified has reached a hundred and fifty thousand annually, or 50 per cent. more than were contained in the International Catalogue of Scientific Literature.

As has been pointed out, the advantage of the system lies in the unification of the work of those adopting it, who thereby contribute towards the formation of a comprehensive index to recorded information. Specialists are enabled to select references to their particular subject from all published bibliographies using the standard system, and incorporate them in a special index to that subject; while large libraries can establish repertories, in which the entries from every source so classified fall together in a single series.

In such an index references to a given topic are brought together by the classification from every group of periodicals containing information on that subject; and references to border-line subjects are classified in such a way as to be available from whatsoever point of view they may be desired. Thus information recorded in a botanical journal is no longer hidden from the agriculturist to whom it may be useful. And all the instruments designed by physicists are labelled so that any one may be found by the physiologist at need. Thus the time of search is reduced from hours to moments at each consultation, while the range of the investigation becomes complete.

Such a repertory has been organised in the Science Library at South Kensington. The index now comprises two million cards covering all branches of science and technology. It is supplemented by an exceptionally extensive collection of miscellaneous bibliographies, which are estimated to contain in all some forty million references. The information service is administered by a scientific staff, who supply lists of papers on special topics on request. Periodicals, from a collection comprising more than ten thousand different sets, are also available for loan to scientific workers through the medium of approved institutions or industrial undertakings with which they are connected.

Partly owing to the success of the Decimal Classification, no doubt, interest in bibliographical problems is again reviving. An extensive review of bibliographical undertakings has been undertaken by an influential body. There are suggestions of more international conferences and for the creation of new classifications, proposals which are calculated to hinder the progress of bibliography and to repeat the expensive failure of the International Catalogue on yet a larger scale. We must consider whether any useful purpose is likely to be served by the international discussion of a problem already solved, and of which the solution has been demonstrated in practice on the largest scale. We have to realise that the whole art of bibliography is not to be comprehended in a day. There is a techique of bibliography, which is to be acquired only by training and experience. While we are seeking for savants to expound developments in their own domain, for the benefit of their colleagues working in other fields, let us be willing to accept the powerful instrument which bibliography places at our disposal, and thus achieve at last true co-operation in science, the need for which has for long been recognised.

Motor Car Developments.

The general and technical character of the Salon de l'Automobile, which opened in Paris last week, has changed with the altered conditions of the motor car industry. French makers have no longer the large and increasing foreign trade that enabled them formerly to extend their manufacturing facilities, and while they have made up some of the lost ground with a growing demand for commercial vehicles, the production of pleasure cars has been steadily declining. Several foreign markets have placed restrictions on the importation of cars. It is estimated that during 1932 the total production of cars in France, both private and commercial, was 171,222, while in 1931 the number was 196,079. This decline in business has had the usual result of stimulating makers to further research in the way of improvements, which are in most cases developments of ideas that have been put tentatively into practice for some years past. So long as rationalisation was the order of the day in the motor car industry, and makers sought to produce cheaply and sell at competitive prices, there was little prospect of any drastic change in car design, but following upon the trade depression, which compelled makers to strive after improvements that would encourage buying, the present Show differs from its predecessors in the presentation of many notable departures from former practice. These ideas are not new, for many of them have been imported from abroad. Their interest lies in the methods of applying them. The pre-selection of gears for synchronising the speeds of pinions before engaging them is worked out in different ways, though it may be remarked that some of the devices are demonstrated on chassis and are not standard fittings on cars offered for sale. Nevertheless, they are all presented by leading makers who would not introduce anything which they did not intend to identify with their cars. In one case, the rotation speeds are controlled by brakes to enable dog clutches to slip into the pinions easily. On the Panhard stand there is an arrangement worked by engine suction for automatically declutching and speed changing. Until recently, automaticity in car driving was deprecated by makers, who declared that the mechanical complication of devices to obtain it was undesirable, while it was argued that extreme facility in handling cars was really not necessary. The way was prepared for this easy car driving by the introduction of the four-speed gear-box, with two pairs of helicoidal pinions in mesh for silent changing, and now that almost complete automaticity has been obtained with a lever on the steering pillar, it is difficult to suppose that it will not become a feature in car design. This innovation lies to the credit of British car makers.

The suppression of direct connections between road wheel axles and the car frame marks another stage towards the provision of complete comfort to car users. Shock absorbers and other more or less ingenious suspensions have helped to attenuate the inconveniences of shocks and jolting on roads, and it is now sought to suppress them altogether by floating the frame on the road wheels. The problem is not easy of solution, since too much flexibility may cause more trouble than the road shocks themselves, and the devices employed must therefore not affect the lateral stability of the car. The most familiar method is the carrying of wheels on parallel transversal springs with hinged tension rods between the hubs and the frame; the Delahaye device is a modification of this arrangement with one transversal spring; the Panhard front axle is pivoted centrally on the frame; a German car has spiral springs between the axle and the frame with connections thereto by hinged yokes; Mathis relies upon a combination of shaft torsion and oil dashpot; and there are, in fact, many different ways of suppressing direct spring connections between the axles and the frame. For many years past cars have been built in France with floating bodies, but they have all disappeared, whether because the public was not prepared for them or because they revealed defects it is difficult to say. The problem is one that needs careful investigation, and as it implies the application of patented arrangements the practice of fitting cars with "independent" wheels will presumably extend gradually. The floating engine is evolved from the same desire to insulate the car body from vibration. A complete suspension of the engine is a delicate matter that has been accomplished in various ways with more or less success, and as progress in this direction is checked by the necessity of adapting a suitable suspension to particular engines the alternative of the three-point suspension with damper arrangements continues to find favour amongst some makers. The practically vibrationless character of some engines produced nowadays tends to lessen the importance of a flexible suspension. The growing practice amongst French makers to shorten engine stroke and run with higher compressions at greater speeds, coupled with facilities for control and gear changing, is in favour of the four-cylinder engine, which is less overshadowed by the six, eight, and twelve cylinder designs. A significant departure has been made by a leading French constructor of small cars who has gone over to the front wheel drive, and has arranged to build such cars under a German licence. The front wheel drive has never been anything more than an experiment, and all efforts to make it popular have failed, so that this mass production of a new type of car is an indication of the belief entertained by some French makers that a drastic change is necessary in order to shake the automobile trade out of its comparative lethargy. As presented, the new front wheel driven car offers distinct advantages in the way of providing ample room for a low frame and spacious body. It is of the floating type, with the rear wheels carried on brackets extending from the ends of longitudinal leaf springs and connected with the frame by hinged rods. This enterprise will show whether the front wheel drive can become a popular success.

Some compensation for the contraction of business in touring cars is provided by the activity of the commercial vehicle section, which is represented for the first time with the pleasure cars instead of lorries and vans, having, as formerly, a separate show of their own. The extraordinary development of road transport in France has been accompanied by progress in lorry design that is observable more particularly in the increasing use of the compression ignition engine and in the building of lorries to carry loads, in one case, up to 17 tons. Judging from complaints it would appear that some French lorry builders have exceeded the weights and dimensions of vehicles that should be permissible on the road. The driving control of such vehicles has necessarily received special attention from makers, and the big lorries are equipped with compressed air cylinders kept charged by an air compressor for actuating the brakes, and on the Renault lorry there is a compressed air servo-control of the steering gear, consisting of a double-acting piston which can be operated from the steering wheel for turning at sharp angles. The commercial vehicle has advanced as rapidly in essential practical details of design as the touring car has improved in refinement, and this progress is distinctly encouraging for an industry which has made great efforts during the year to prepare for a renewal of activity. It may, nevertheless, be supposed that competition will become increasingly keen for business.

Contrary to the experience of last year, there is a big foreign participation in the Show. Several German firms exhibit together under conditions suggesting that they form one commercial group. Some others have separate stands, notably M.A.N., with engines and a big lorry. The British industry is also well represented. The Show, on the whole, appears to indicate a turning point in motor car construction in the way of developing ideas that may have a permanent influence on the general design of motor vehicles in the future.

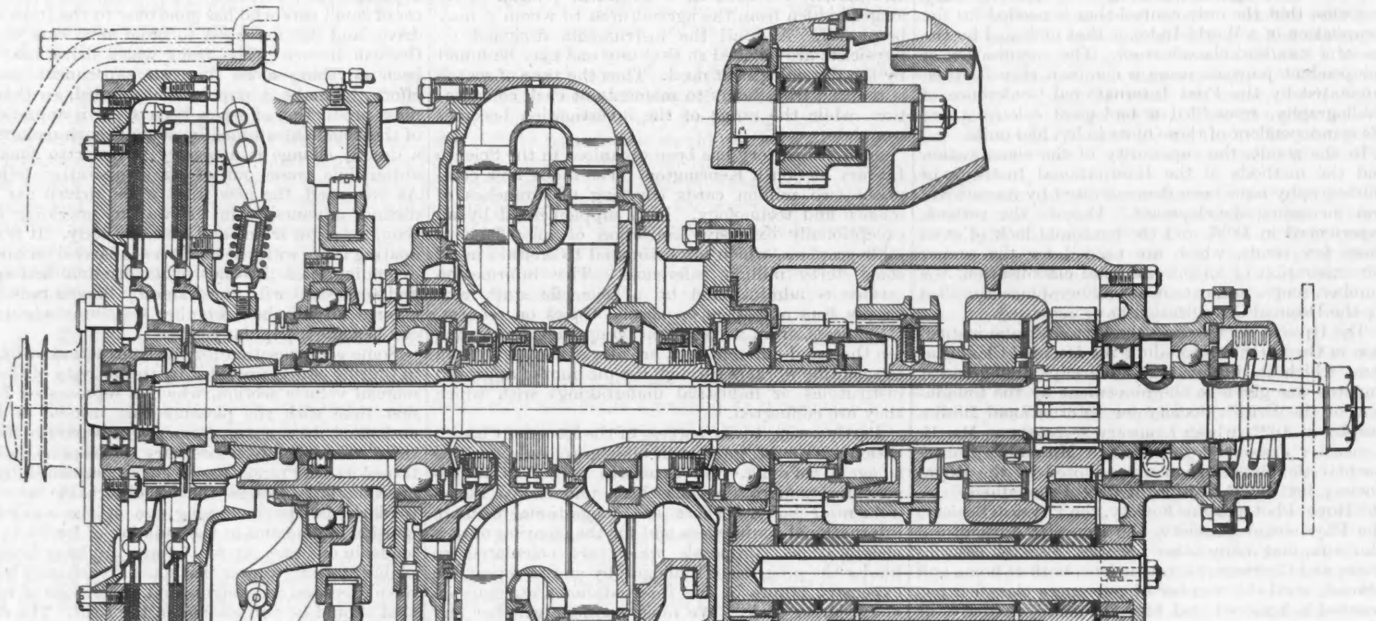
RAILWAYS IN THE PEAK DISTRICT.

The Wirksworth branch of the former Midland Railway has been somewhat in evidence of late because of the demolition of the occupation overbridge mentioned in our Seven-day Journal of September 29th. This short line of 8½ miles, opened on October 1st, 1867, is of historical interest in view of the part it was intended to play in the Midland Railway reaching Manchester. In the middle 'forties there was no railway communication in the Peak of Derbyshire between Ambergate on the Derby and Leeds of the Midland, and Stockport on the Manchester and Crewe Railway. There was, however, the High Peak Railway, opened in 1825, which joined the Cromford Canal with the Peak Forest Canal by a tramroad, but its gradients made it altogether unsuitable for a main line. The two companies named decided to build jointly a line from Ambergate to Stockport and the latter acquired the High Peak Railway. The scheme did not meet with the support of the London and North-Western when the Manchester and Crewe became part of that system in 1846, and it ended in a line being built from Ambergate to Rowsley, which, with the Cromford Canal, was leased to the L. and N.W. and Midland jointly. Because of that joint ownership with its great rival, the Midland determined upon an independent route from Derby through Wirksworth to Rowsley, and the Wirksworth branch, which leaves the Midland main line at Duffield, was the result. But it did not go farther. The L. and N.W. lease was to expire in 1871 and it was not therefore to that company's interests to fight, and the Midland first got a line from Rowsley to Buxton—sanctioned in 1860 and opened to Hassop on August 1st, 1862, and completed on June 1st, 1863—and from Millers Dale to the Manchester, Sheffield and Lincolnshire at New Mills—sanctioned in 1862 and opened on January 24th, 1867. The bridge on the Wirksworth branch, just destroyed, was an occupation overbridge to connect two portions of property that tbe new railway divided. Its construction is indicative of what railway companies paid in those days for compensation to landowners.

As an extraordinary example of welding of inflammable materials, satisfactory welds have, says Mr. A. Stephenson, in the *Journal* of the Royal Society of Arts, been made of celluloid with the acetylene-air flame, but not with the oxy-acetylene.

HYDRAULIC TORQUE CONVERTER, CLUTCH SYSTEM, AND REVERSE GEARBOX

LEYLAND MOTORS LTD., LEYLAND, LANCASHIRE, ENGINEERS



An Hydraulic Torque Converter.

SINCE the early days of motoring "crash" gears have been in use in the transmission systems of petrol-driven road vehicles. It is only within the last few years that devices that may mitigate the difficulties of gear changing or do away altogether with the gear-box have been developed. In any case, whatever device is fashioned to take the place of the conventional gear-box, it must have the characteristic of coupling the engine to the road wheels flexibly; that is, the engine must be able to run at a high speed while the road wheels are rotating slowly and the torque developed by the engine must be multiplied in the final drive shaft. Several types of hydraulic transmissions have been developed for road vehicles since the war, but except for the fluid fly-wheel, of which the characteristics still demand that a gear-box shall be included in the transmission system if the best results are to be obtained, no such device has come into general use.

On a recent visit to Leyland Motors, Ltd., of Leyland, Lancashire, we were privileged to inspect a hydraulic torque converter on the Lysholm-Smith system, which the firm is now putting into production. At the Commercial Motor Transport Exhibition, which opens at Olympia, London, on November 2nd, this converter will be shown as an alternative transmission system to the conventional clutch and gear-box in motor coaches and omnibuses. Several engravings accompanying this article illustrate the construction of this device, the most useful of which for reference purposes is the sectional drawing reproduced above. A glance at that drawing is enough to show that more is indicated there than merely the torque converter itself. On the engine side there is a system of clutches and on the other a reverse gear-box.

Since the characteristics of the torque converter itself influence the design of the other parts shown in the drawing it will perhaps be best to begin our description with that mechanism. It is, as might be inferred from the drawing, of the hydraulic type. One of the tone engravings—Fig. 1—shows the various parts of the device separated. Driven by the engine, there is a rotor in form much like the impeller of a centrifugal pump. Partly surrounding the "impeller" is the "rotor," which is connected to the road wheels and upon which are mounted three rows of blades not unlike those of a steam turbine. The casing into which these two parts fit carries two rows of fixed blades, which guide the hydraulic fluid on to the blades of the "rotor." The relative positions of the fixed and moving blades when the converter is assembled may easily be followed from the drawing. The hydraulic fluid follows, of course, a closed path, being driven outwards by the "impeller" and travelling inwards through the blades of the rotor. Its pressure varies from about 25 lb. per square inch at the centre to about 50 lb. per square inch at the outside.

Although this converter is a form of hydraulic coupling, its design is distinctively different from that of a fluid fly-wheel and its characteristics, as might be expected, are also different. Whereas a fluid fly-wheel is constantly in use, it does not take the place of a gear-box, while this torque converter, which takes the place of a gear-box, is not constantly in action; it is, in fact, at its best at low vehicle speeds and, when a certain optimum speed is reached, it is "cut out" of action and a change over is made to direct drive. What that optimum speed may be depends on the design of the converter and the arrangement of the blading. Since a continuous high rate of acceleration, uninterrupted by the necessity to change gear, is obtainable when the device is in use, this torque converter is likely to make a place for itself in the transmission systems of omnibuses designed for service in urban areas. The constant starting and stopping in such service will give scope for the converter to develop its accelerative possibilities while relieving the driver of the labour of continual gear changing. In Fig. 3 there is reproduced a graph supplied to us by the makers showing the acceleration obtainable with an ordinary gear-box and with the torque converter. Both curves refer to the "Titan" type of omnibus. For the reasons given above a speed of about 20 miles per hour has been adopted as the optimum for the converter drive, and for greater speeds a clutch mechanism is provided, by the use of which a direct drive may be obtained.

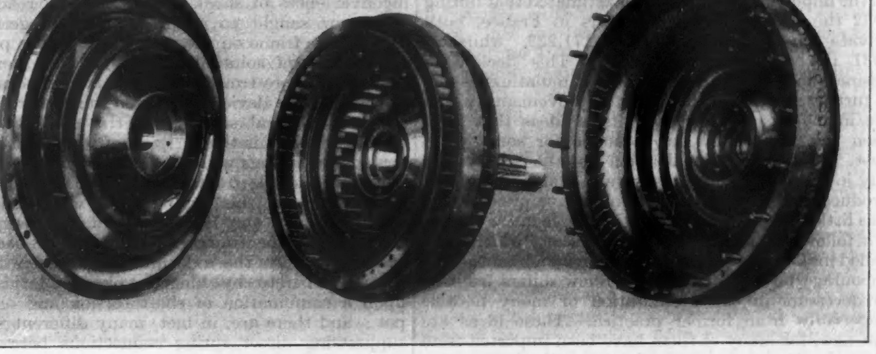


FIG. 1—PARTS OF HYDRAULIC TORQUE CONVERTER

On the end of the engine crank shaft there is mounted a dished fly-wheel encasing the clutch plates. There are two sets of plates, either of which may be brought into action by a mechanism that is so clearly indicated in the drawing and the tone engraving, Fig. 2, that there is no need further to refer to it. A "neutral" position when neither clutch is engaged is also available. By bringing the left hand set of plates into action a drive is obtained directly from the engine to a solid central shaft passing right through the arrangement of mechanisms under discussion and connected at its further end to the road wheels in a perfectly straightforward, normal manner. Thus direct drive is obtained. Throwing over the clutch-actuating mechanism to its alternative position connects the engine to a sleeve surrounding the central shaft and forming part of the "impeller" of the torque converter. The details as to how the central shaft and the sleeve are carried on ball and roller bearings clear of one another may be followed from the drawing. Following up the drive through the torque converter, it will be seen that a sleeve enclosing the central shaft also forms part of the "rotor" and projects into the reverse gear-box. About midway along the length of the gear-box it is externally splined to carry the moving portion of a dog clutch. Slid to the right—see the drawing above—this clutch engages with the inner member of a free-wheel mechanism, the outer member of which is mounted on the central shaft. The drive is thus transmitted from the "rotor" of the converter through the free-wheel to the central shaft and thence to the road wheels. This position is that normally occupied by the dog clutch, and the reason for the insertion of the free-wheel, even if it were not a desirable feature in other respects, will be realised after a moment's consideration. For when direct drive is engaged the "rotor" of the converter would be turning at the same rate as the central shaft and churning the oil with a consequent loss of power if it were not for the presence of the free-wheel mechanism. As the free-wheel is present the two rotary parts of the converter are both left free to rotate or remain stationary according to the effect of any small frictional forces that may act upon them. To obtain reverse the dog clutch is disengaged from the central member of the free-wheel and slid towards the left. Since the engine is running, as soon as this clutch is disengaged the "rotor" of the converter will begin to turn, carrying with it the sliding member of the clutch. At the same time the pinion of the reverse gear train with which the dog clutch is to engage is held stationary by its connection with the road wheels through the idler gear, lay shaft, and central shaft. To bring the "rotor" to rest the mechanism is so arranged that a simple cone clutch first makes engagement; subsequently, when rotation has been prevented, the outer ring of the dog clutch sliding member engages with suitable teeth cut on the side of the "reverse" pinion. The illustration Fig. 4 shows the central shaft and the various parts that are situated in the gear-box.

The general arrangement of the complete mechanism having now been described, it remains to refer shortly to several details. Firstly, those wise in the design of centrifugal pumps will see that by allowing the oil from the central portion of the converter to have access to the outer sides of the "impeller" and "rotor" over part of the area hydraulic balance is at least partially obtained, so that any residual thrust is easily taken by the large ball bearings on which the rotors are mounted. The most serious possibility inherent in the design is that leakage of fluid from within the converter may take place. Since the pressure of the oil within the converter may rise in the central space to 25 lb. per square inch, special precautions are necessary. To prevent the oil leaking out through the clearance between the "impeller" and "rotor" to the space around the central shaft and thence escaping longitudinally along that shaft, a copper bellows gland is fitted between the two rotating parts. Similar copper bellows glands prevent the oil escaping from the spaces behind the rotors along the outer surfaces of the sleeves. It is impossible, however, to prohibit leakage altogether, nor in the interests of lubrication would it be desirable to do so, and special passages are provided in the casing to collect any oil that does escape. These passages are easily traced on the drawing. A reserve oil tank is mounted on the dashboard of the chassis, and the leakage oil is conveyed to this tank by an injector, the high-pressure oil for which is obtained from the "pressure" side of the converter. A similar injector forces the oil from the reserve tank back into the spaces behind the "rotors" of the converter.

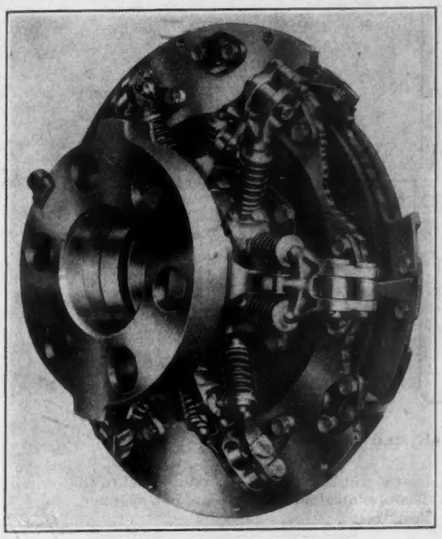

FIG. 2—CLUTCH OPERATING MECHANISM

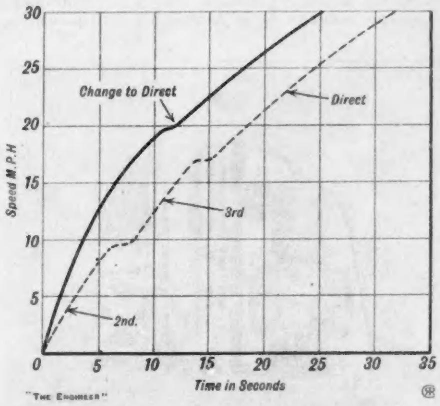

FIG. 3—"ACCELERATION" CURVES

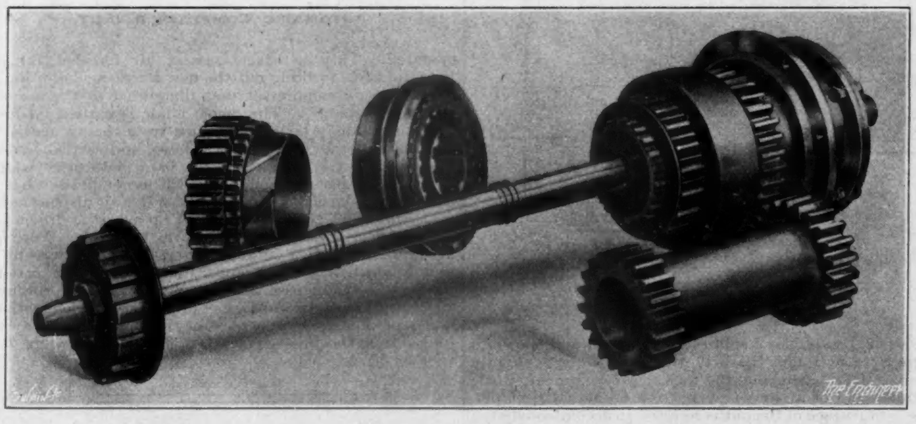

FIG. 4—CENTRAL SHAFT AND PARTS SITUATED IN GEARBOX

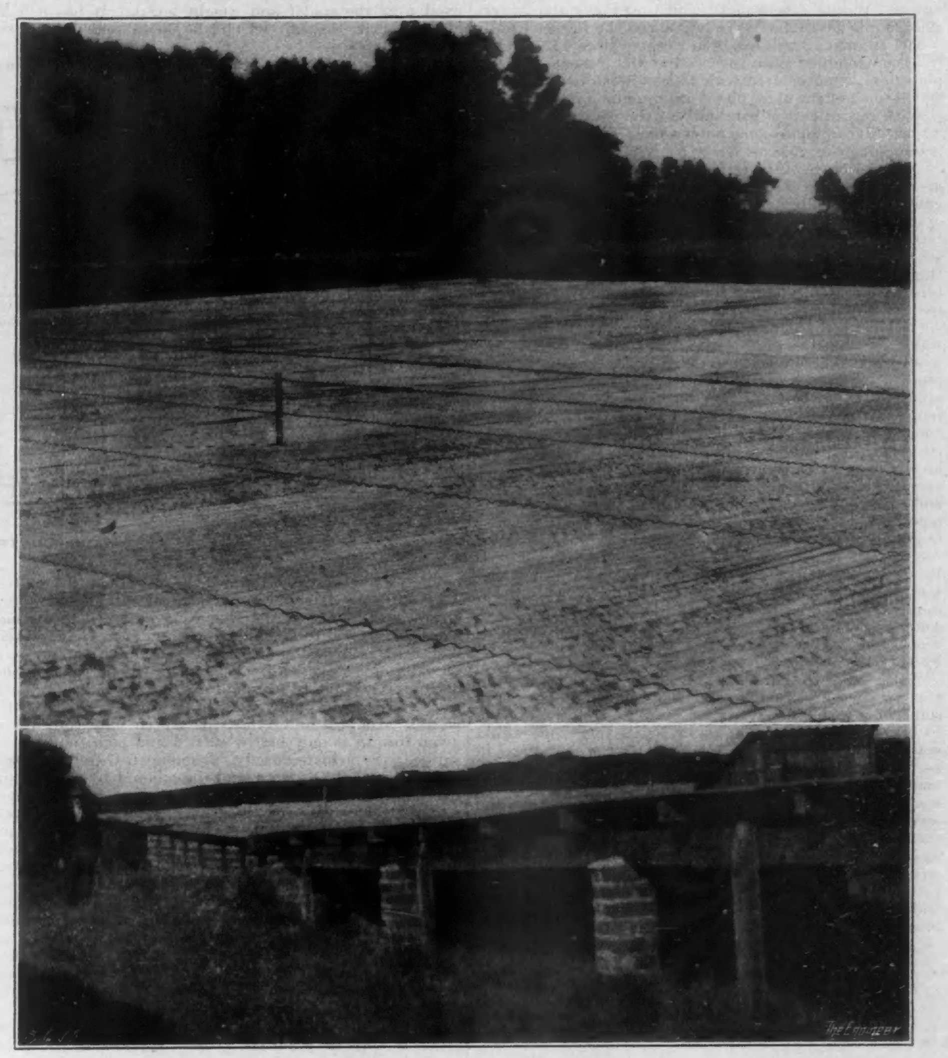
Under certain conditions new fluid, when introduced into the converter, may gasify to a slight degree. To avoid the possibility that trouble might arise from this cause a permanent "leak-off" pipe is provided at the top of the casing, through which the fluid flows to the reserve tank already mentioned. A small air-cooled radiator is included in order that prolonged use of the converter under extreme conditions—on a long steep gradient, for instance—shall not cause an undue temperature rise of the fluid. Usually a mixture of paraffin and lubricating oil or ordinary fuel oil, as used for compression-ignition engines, is used in the converter.

While we were at the works we were given the opportunity of testing a TD-3 "Titan" chassis, fitted with one of these converters on the road. The controls under the charge of the driver comprise an accelerator, brake pedal, and a lever controlling the clutches for "direct" or "converter" drive. There is, of course, no gear changing in the ordinary meaning of the term. The chassis was fitted with a petrol engine developing a maximum output of 110 brake horse-power. At speeds below 20 miles an hour with the converter in operation a great degree of flexibility is obtained. For instance, the vehicle, while climbing a hill, was required to turn to the right into a main road. It was baulked by the arrival of another car coming along the main road. In an ordinary omnibus or lorry the circumstances would have called for a rapid gear change at a time when the driver was occupied in avoiding the other vehicle. With the converter in operation, however, it meant no more than releasing the accelerator pedal for the few seconds necessary to allow the other vehicle to pass and subsequently depressing it again to accelerate smoothly across the road. The impossibility of stalling the engine was demonstrated on a steep hill, when the vehicle was allowed to come to rest and even to run backwards with the engine running. The smoothness with which the drive was taken up when the accelerator was again depressed was also noticeable. Having found a straight piece of road, which, unfortunately, was not absolutely level, we, personally, obtained the following acceleration figures by the use of a stop watch and the speedometer fitted to the vehicle :—

Speed.	Up. Seconds.	Down. Seconds.	Average. Seconds.
10 m.p.h.	4	3	3·5
15 ,,	6	5·25	5·62
20 ,,	12	10·5	11·25

The chassis with its load weighed 9 tons 17 cwt. and carried five passengers when these readings were taken, and, except for the torque converter, was standard in every respect. Owing to its smoothness the rate of acceleration was very deceptive to the passengers, seeming very much less than it really was. At 20 m.p.h. the change was made to direct drive. These tests fully justified the opinion of the manufacturers that the "torque converter" vehicle might appeal to omnibus service operators.

RAIN WATER CATCHMENT FOR A COUNTRY HOUSE



The Water Supply of a Country House.

THROUGH the courtesy of Mr. C. J. P. Cave, of Petersfield, we are able to give some technical particulars of a rain-water catchment he has erected in his grounds for the water supply of his house. Whilst the normal rainfall in the Petersfield district is on the high side—40in. p.a.—and thus favours the method he has adopted, yet the arrangement is so simple that other landowners who are forced to depend upon rain will be glad to have the following notes about the construction and operation.

Broadly, the catchment consists of an area of corrugated iron sheets laid upon wooden supports carried on short brick piers, as shown in the accompanying illustration. The sheets are laid with a slight fall towards a central gutter which runs transversely across the catchment. The sheets are raised about 4ft. above the ground at the outer ends and 3ft. at the centre, and the total effective area is 7670 square feet. The catchment is roughly square, measuring about 90ft. each way, with, however, a piece cut out to allow access to the valves which control the outlets of the tanks. Below the catchment there are brick tanks lined with cement, but the rain water passes through a gravel filter before entering these tanks. About 3000 gallons of water are secured for a rainfall of 1in.

In consequence of the small slope of the sheets—about 1 : 50—Mr. Cave found that there was a tendency for the water to run back under the edge owing to capillary attraction and thus fall outside the cross gutter. The loss that occurred in this way was considerable—between

30 and 40 per cent.—but rather than go to the trouble and expense of moving all the plates further forward over the gutter Mr. Cave adopted the following ingenious plan. He drilled holes in the valleys near the lower edge and dropped through them nails, which overhang the gutter. This simple device has entirely stopped the former loss.

The original system has been working since 1921, but it has been enlarged since then and at the present time the plates are being painted with cement wash to check rust which some of the older plates are beginning to show.

With regard to the potability of the water, we cannot do better than quote some notes which Mr. Cave has been good enough to give us.

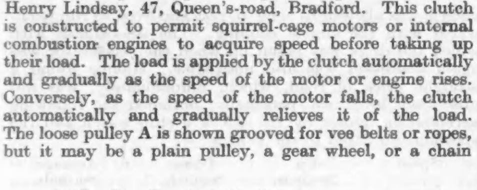
"As to storage of the water, I have always found that it keeps perfectly in the underground tanks. At one time we gave an extra filtering to the drinking water, but, in my opinion, this was quite unnecessary, and as a matter of fact we are not using the extra filter now. I cannot understand the prejudice against rain water stored in tanks. I think it must arise from people letting rain water run into tanks without filtering it through gravel. Our water is quite palatable and quite tasteless.

"I have had trouble with pipes owing to the very soft water. I understand that rain water takes up CO_2 very readily and that this makes it slightly acid. Anyhow, the pipes of the hot water supply (not the central heating apparatus) gave trouble. The hot water used to run very red, and after a time pipes began to leak, and others got choked up, and I had to renew a number. I am told that the pipes that were most affected were what, I believe, are known as red steam pipes, and I do not know how these came to be used. This house was originally a farmhouse and has been added to more than once. Anyhow, the new pipes are galvanised iron pipes. But to guard against anything of the sort happening again I installed a water 'softening' apparatus of Messrs. Boby and Co., of 62, Brook-street, which has the effect of neutralising the acidity of the water. This seems to have made a great improvement; the hot water no longer runs red. The water is still quite soft, but it is not as excessively soft as it was before. All the water that is pumped into the roof by the electric pump passes through the apparatus.

"This house stands 750ft. above the sea, and parts of this parish of Froxfield are over 800ft. above the sea. The soil is clay with flints overlying chalk. A well would have to be very deep to obtain water, and I fancy one would not know till one had sunk it how ample the supply would be. Almost all the parish depends on rain water, but many of the farms have a very inadequate supply. I consider that my catchment has been a great success, and several times in recent years I should have had to shut up the house and go away if I had depended only on the water from the roof. This year we have had an ample supply, and I have enough water to carry me on till January without any further rain, allowing 400 gallons a day; and we have not had to economise in water at all or even to ask people to be careful about bath water."

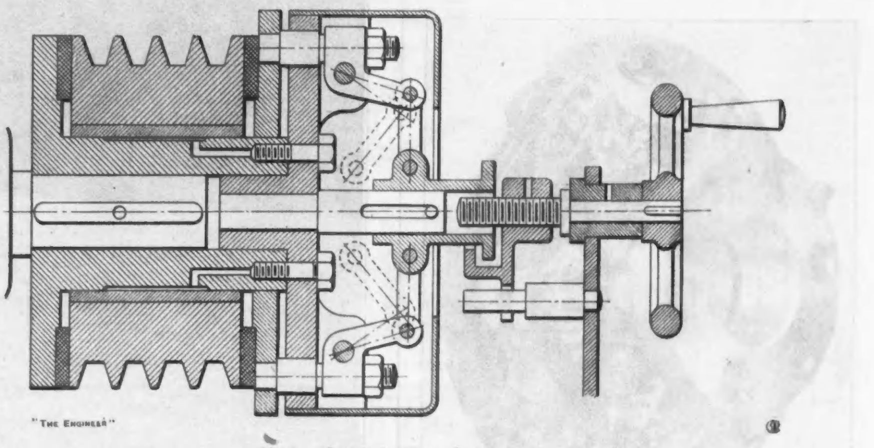
Automatic Centrifugal Clutch.

We illustrate herewith a design of automatic centrifugal clutch of the plate type developed and produced by Mr. Henry Lindsay, 47, Queen's-road, Bradford. This clutch is constructed to permit squirrel-cage motors or internal combustion engines to acquire speed before taking up their load. The load is applied by the clutch automatically and gradually as the speed of the motor or engine rises. Conversely, as the speed of the motor falls, the clutch automatically and gradually relieves it of the load. The loose pulley A is shown grooved for vee belts or ropes, but it may be a plain pulley, a gear wheel, or a chain sprocket wheel. It is mounted between a boss plate M keyed to the driving shaft and a pressure plate N sliding on the boss of the plate M. Friction surfaces composed normally of compressed cork are attached to these two plates to establish contact between them and the edges of the loose pulley. Attached to the end of the boss of the plate M and revolving with it is a spider to which two or more bell-crank levers W are hinged. These levers are of about 3 to 1 ratio, and are constructed in the form of weights. Each contains an adjusting screw, the point of which bears against the pressure plate N. As the motor gathers speed centrifugal force causes the weight levers to exert an increasing thrust on the pressure plate. Slipping occurs at first at the friction surfaces, but as the speed rises still farther the thrust exerted by the weight levers gradually becomes sufficient to cause the loose pulley to pick up the speed of the driven shaft. The adjusting screws provide a means of taking up wear of the friction surfaces. The compressed cork employed for these surfaces is stated to be very resistant to wear, and to possess the valuable characteristic of not losing any material portion of its driving capacity when it becomes greasy. A light aluminium cover is fixed over the spider and weight levers. It has a hole at its centre through which the loose pulley may be lubricated.



AUTOMATIC CENTRIFUGAL CLUTCH

For use in conjunction with single or two-phase motors having a low starting torque, the action of the clutch may be delayed by means of control springs extending between the ends of the weight levers. These springs can be subjected to fine adjustment and can be employed if desired as a means of causing the clutch to slip at a predetermined overload. It is pointed out that as the drive is transmitted through friction surfaces on both sides of the loose pulley, the thrust to be exerted by the weight levers, in order that the clutch may transmit a given torque, is only half what it would be if the friction surface were on one side only. Economy is thereby effected in the size of the weights, and the amount by which they overhang the shaft is reduced. There is no actual clearance between the driving and the driven parts, and, as a consequence, the clutch operates without backlash or vibration.

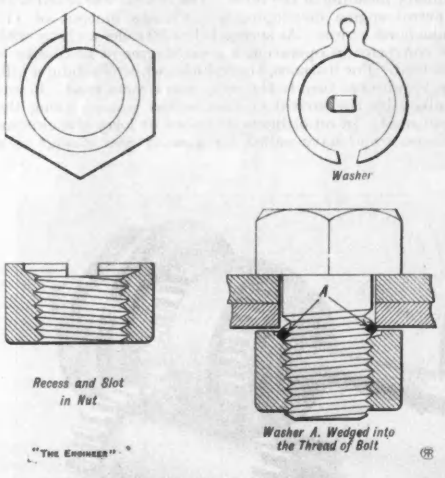


HAND-CONTROLLED CLUTCH

In our second engraving we illustrate a modification of the design in which the automatic action of the clutch is replaced by a hand control. In this case the thrust on the pressure plate is exerted by bell-crank levers linked to a sliding collar controlled by a hand wheel and screw. If the position of the motor is adjustable on slide rails two flat bars are inserted between the feet of the motor and the rails, and the motor fixing bolts passed through them. These bars are extended and at their end carry the bracket in which the control screw of the clutch is supported. By this means the position of the motor on its rails may be adjusted without dislocating the hand control gear.

A New Lock Nut.

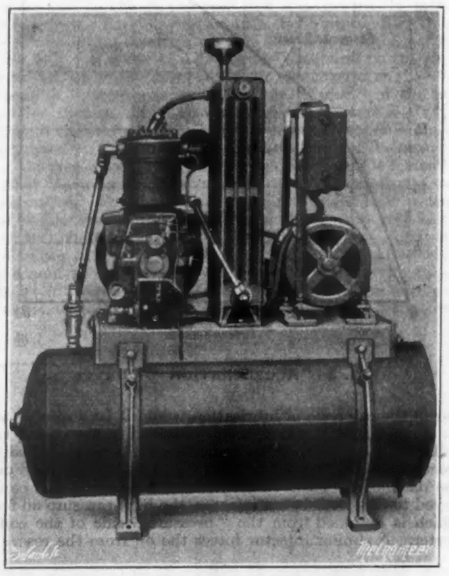
The "Dean" locknut illustrated herewith is made by the Aerogen Company, Ltd., Chalk Farm-road, London, N.W.1. It is claimed to be a simple and effective combination of a nut and a washer that will hold tight on a bolt against violent and long-continued vibration and to be capable of being removed easily and repeatedly without doing damage to either the nut itself or the bolt. The "washer" resembles a split pin opened out and bent into a circle to fit round the bolt with the two ends slightly apart. In an emergency the washer can be quickly made with the aid of a pair of pliers from an actual split pin. The contact face of the nut is recessed to accommodate the washer, a slot being cut from the recess to one of the nut corners to take the folded head portion. The bottom of the recess is coned. When the nut is screwed down against a metal surface the washer, by virtue of its half-round shape and the conical bottom of the recess, becomes slightly twisted and is kneaded into the thread all round the bolt and also into the turn of the thread extending below the plate surface. The tongue of the washer held by the slot locks the nut against loosening under vibration. An additional locking action is produced by the head of the washer lying in the slot. When the nut is nearly home this head makes contact with the metal surface and, lying as it does at a considerable leverage, produces an imperceptible tilting which has the effect of slightly "bastardising" the thread. The washer is made of soft iron and is claimed to cause no damage to the thread. The same nut can be used repeatedly on the same bolt with a new washer at each application. The effort required to loosen the nut is stated to be about equal to that required to shear a pinned nut with the aid of a spanner.



THE "DEAN" LOCKNUT

An Automatic Compressor Unit.

More and more is the modern garage becoming mechanised. It is only a surprisingly short while ago that all greasing was performed with the hand-operated grease gun, and the setting of tire pressures was achieved with a foot pump. A back-aching crawl was necessary if some adjustment had to be carried out beneath the car. The coming of the automatic compressor set has altered all that. Nowadays, greasing and tire-pumping are performed by the help of air pressure; air-operated tools are used in the repair department, and few "up-to-date" garages can afford to be without a hoist, frequently air operated. This increasing use of air has led B.E.N. Patents, Ltd., to bring out the new larger model of automatic electric compressor unit illustrated in the accompanying engraving. The whole affair is carried on four legs within the "bows" of which rests the air receiver, 20in. diameter by 60in. long. Above, and carried by the legs and not the receiver, is the base plate upon which the working parts are mounted. The compressor has a bore and stroke of 4in. by 4in., with a free air displacement of 20 cubic feet per minute at 695 r.p.m. It is driven by a 5 H.P. electric motor through a twin "V" belt. Working in conjunction with a suitable starter, there is a "pressure" switch which makes the apparatus automatic in action. Between the compressor and the motor a radiator, through which the cooling water flows by thermo-syphonic action, is mounted. The compactness of the whole affair may be judged from the dimensions. It is 5ft. 6in. long by 2ft. 7in. wide by 5ft. 3in. high.

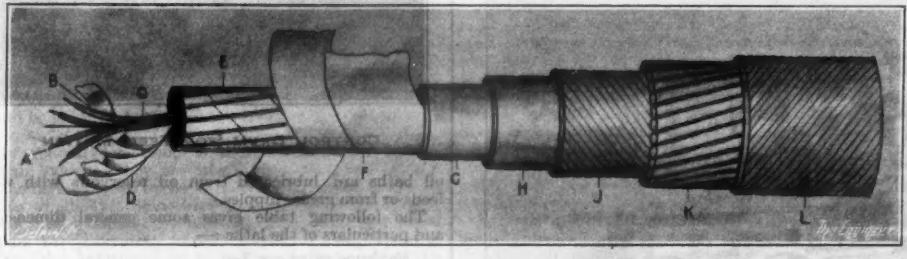


AUTOMATIC COMPRESSOR UNIT

The Anglo-French Telephone Cable.

Details are now available of the Anglo-French submarine telephone cable, which was laid on September 18th from St. Margaret's Bay, near Dover, to the Bassin des Chasses, near Calais, for use in connection with the proposed "on demand" trunk service to the Continent. From the English shore the cable is extended by an unarmoured lead-covered length of similar cable core drawn into a conduit and running to a repeater station on the cliff above the landing point. At the French end it is connected to a tape-armoured cable about 1½ miles long, terminating at a repeater station on the outskirts of Calais. As the distance between repeater stations is such as to ensure satisfactory transmission, the cable is not loaded. A land cable connected to the submarine cable at St. Margaret's Bay extends to London and is provided with suitable repeater stations, whilst on the French side a new cable has been laid to connect the Calais repeater station with Paris. The cable is designed for four-wire working. Speech from London will reach Paris by way of one pair of wires in the quad, while the return speech will be transmitted over the other pair in the same quad. In addition to the circuit at audio frequency provided by each quad there will be another circuit operated at a carrier frequency.

Some of the circuits in the new cable will terminate at Paris, while others will be extended to Geneva, Rome, Madrid, Marseilles, and other large Continental cities. The telephone facilities will not only be increased, but a higher grade of speech will also be obtained. The accompanying illustration shows the construction of the cable.

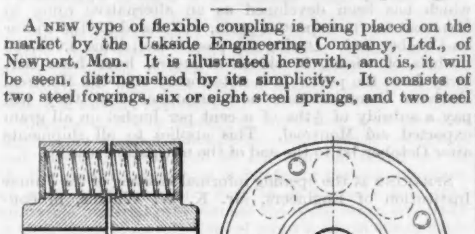


DETAILS OF THE ANGLO-FRENCH TELEPHONE CABLE

A is solid annealed copper wire weighing 66 lb. per statute mile and with a diameter of 0·064in. B is insulation composed of helical lappings of undyed insulating paper, C four conductors insulated in this way and stranded on a paper centre to form a compact quad. Insulated conductors at the ends of each diagonal of the quad form a telephone pair, which may be used separately or as a part of a four-wire circuit. Each quad, lapped with paper D, is marked for identification and is electrostatically screened by means of a helical lapping of metal foil, nineteen quads E being stranded into a compact cable. The stranded cable is covered with a lapping F of stout cut cotton tape and insulating paper and is sheathed, as indicated at G, with an alloy containing about 99 per cent. Imperial lead, the diameter being 1·58in. A waterproofing covering of rubber treated with rubber tapes is shown at H, a covering of compounded and tarred jute yarn to form a bed for the armouring at J, an armouring of twenty-five specially compounded No. 2 gauge galvanised iron wires at K, and a covering of special waterproof compounds and tarred jute yarn at L. The finished diameter of the cable is 2·95in. The main contractors were the Telegraph Construction and Maintenance Company, Ltd., and Standard Telephones and Cables Ltd. acted as sub-contractors.

The Uskside Flexible Coupling.

A NEW type of flexible coupling is being placed on the market by the Uskside Engineering Company, Ltd., of Newport, Mon. It is illustrated herewith, and is, it will be seen, distinguished by its simplicity. It consists of two steel forgings, six or eight steel springs, and two steel cover plates. The makers claim that it is extremely flexible, and inform us that they propose to manufacture it in all sizes from 5 to 1000 H.P. or more. They are at present producing one to transmit 200 to 300 H.P. for use in conjunction with heavy-duty mine haulage gear. The new design takes the place of flexible couplings employing rubber blocks or rubber sleeves previously made by the company.



USKSIDE FLEXIBLE COUPLING

Public Works, Roads and Transport Congress and Exhibition (1933).

THE Congress Organising Committee of the Public Works, Roads and Transport Congress and Exhibition, which is to be held at the Royal Agricultural Hall between November 13th and 18th, has issued the following preliminary programme :—

MONDAY, NOVEMBER 13TH.

At 3 p.m., conference under the auspices of the Institution of Sanitary Engineers on "The Re-sewerage of Guildford," by Mr. J. W. Hipwood, M. Inst. C.E., M. Inst. M. and Cy. E., M.R. San. I., Borough Surveyor of Guildford; Chairman, Mr. H. C. Adams, M. Inst. C.E., M.I. Mech. E., F.R. San. I., President of the Institution.

At 3 p.m., conference on "Town Building L.C.C. Cottage Estates (Post-war)," by Mr. H. Berridge, C.I.E., O.B.E., M. Inst. C.E., M. Inst. Mech. E., late Assistant to Administrator, L.C.C. Housing Development Schemes; Chairman, Sir Arthur B. Lowry, C.B., Deputy Secretary, Ministry of Health.

TUESDAY, NOVEMBER 14TH.

At 11 a.m., conferences under the auspices of the Society of Chemical Industry on (*a*) "Laboratory Tests and their Correlation with Full-scale Road Experiments," by Mr. R. G. C. Batson, M. Inst. C.E., M.I. Mech. E.; (*b*) "Some Factors Involved in the Mechanical Testing of Bituminous Mixtures," by Mr. W. G. Adam, B.A., M.I. Chem. E., F.I.C., and Mr. D. G. Murdoch, B.Sc., A.I.C., A.M.I. Chem. E.; (*c*) "The Mechanical Testing of Bituminous Road Mixtures," by Mr. Prevost Hubbard, Chemical Engineer, The Asphalte Institute, New York; Chairman, Major F. C. Cook, D.S.O., M.C., M. Inst. C.E., Deputy Chief Engineer, Ministry of Transport.

At 11 a.m., conferences under the auspices of the Institution of Gas Engineers on (*a*) "Dry Purification: Some New Methods for its Control," by Mr. W. A. Currie, jun., A.M. Inst. Gas E., Technical Assistant, Glasgow Corporation Gas Department; (*b*) "Qualities of Tars for Use on Roads," by Mr. W. E. Cone, Technical Adviser, British Road Tar Association; Chairman, Mr. F. P. Tarratt, M. Inst. C.E., M. Inst. Gas E., President of the Institution.

At 3 p.m., conferences under the auspices of the Society of Chemical Industry on (*a*) "The Mechanical Testing of Asphalt," by Mr. D. M. Wilson, B.Sc., A.I.C.; (*b*) "Mechanical Tests and the Modern Highway," by Mr. D. C. Broome, M.I.P.T., and Mr. A. R. Thomas, M.I.P.T.; (*c*) "Mechanical Testing of Bituminous Road Materials," by Professor Dr.-Ing. E. Neumann, Stuttgart, Germany; (*d*) "Mechanical Testing of Road Materials—Italian Practice," by Signor Vandone, Italian Roads Laboratory, Milan; Chairman, Professor G. T. Morgan, O.B.E., D.Sc., F.R.S., Past-Vice-President of the Society.

At 3 p.m., conference under the joint auspices of the Association of Public Lighting Engineers and the Institution of Gas Engineers on "The Lighting of Arterial Roads by Gas," by Mr. A. M. Bell, A.M. Inst. Gas E., Public Lighting Superintendent, Tottenham and District Gas Company; Chairman, Mr. E. M. Severn, President of the Association of Public Lighting Engineers.

WEDNESDAY, NOVEMBER 15TH.

At 11 a.m., conference under the auspices of the Institution of Municipal and County Engineers on "Specifications in the Light of Tradition, Experience and Research," by Mr. B. Price Davis, F.S.I., M. Inst. M. and Cy. E., M.R. San. I., L.R.I.B.A., City Engineer, Bangor; Chairman, Major L. Roseveare, O.B.E., M. Inst. C.E., Borough Engineer, Eastbourne, President of the Institution.

At 11 a.m., conferences under the auspices of the County Land Agents' Association on (*a*) "Allotments and Small Holdings," by the late Mr. F. H. Osmond-Smith, F.S.I., formerly County Land Agent for Glamorgan; (*b*) "Rats and Musk Rats," by Mr. M. A. C. Hinton, Deputy Keeper of Zoology, Natural History Museum; Chairman, Sir Charles J. Howell Thomas, K.C.B., C.M.G., Permanent Secretary, Ministry of Agriculture and Fisheries.

At 2 p.m., distribution of prizes by the Right Hon. Sir Hilton Young, Minister of Health.

At 3 p.m., conferences under the auspices of the Institution of Municipal and County Engineers on (*a*) "The Development of Road Bridges in Great Britain," by Mr. C. H. Bressey, C.B., C.B.E., F.S.I., Chief Engineer, Roads Department, Ministry of Transport; (*b*) "The Design of Superstructures for Small Bridges," by Mr. H. C. Adams, M.A., Assoc. M. Inst. C.E., Assistant Engineer, Roads Department (Bridge Section), Ministry of Transport; Chairman, Sir Henry P. Maybury, G.B.E., K.C.M.G., C.B., President of the Institution of Civil Engineers and Chairman of the Congress Organising Committee.

THURSDAY, NOVEMBER 16TH.

At 11 a.m., conferences under the auspices of the British Waterworks Association on (*a*) "Pooling of Supplies by Interconnection of Water Undertakings and their Trunk Mains through Rural Areas," by Mr. Alan E. L. Chorlton, C.B.E., M.P., M. Inst. C.E., M.I. Mech. E.; (*b*) "Water Pollution Research," by Dr. A. Parker, D.Sc., M.I. Chem. E., F.I.C., Secretary and Assistant Director of Research, Water Pollution Research Board, Department of Scientific and Industrial Research; Chairman, Mr. G. M. Robertson, J.P., Chairman of the Fylde Water Board, President of the Association.

At 11 a.m., conferences under the auspices of the Institution of Municipal and County Engineers on (*a*) "Office Efficiency in a Highways Department," by Mr. E. Tasker, Chief Engineering Assistant, Gloucestershire County Council; (*b*) "Control over Highway Expenditure," by Mr. P. Tait, Finance and Statistics Department, Ministry of Transport; Chairman, Mr. C. H. Bressey, C.B., C.B.E., F.S.I., Chief Engineer, Roads Department, Ministry of Transport.

At 2.45 p.m., conferences under the auspices of the British Waterworks Association on (*a*) "The Financial Management of Municipal Trading Departments," by Mr. Sydney Larkin, F.S.A.A., F.I.M.T.A., City Treasurer, Coventry; (*b*) "Water Supply and Fire Protection," by Mr. John Smith, Chief of the Belfast Fire Brigade; Chairman, Mr. G. M. Robertson, J.P., President of the Association.

At 3 p.m., conference under the auspices of the Institution of Municipal and County Engineers on "Some Considerations Affecting the Economical Reconstruction of Rural Roads," by Mr. D. G. R. Tiddy, F.S.I., M. Inst. M. and Cy. E., District Highway Surveyor, Somerset County Council; Chairman, Major L. Roseveare, O.B.E., M. Inst. C.E., Borough Engineer, Eastbourne, President of the Institution.

FRIDAY, NOVEMBER 17TH.

At 11 a.m., conferences under the auspices of the Institute of Sewage Purification on (*a*) "Recent Developments in Methods of Sewage Works Analysis," by Mr. J. T. Thompson, M.Sc., F.I.C., Chemist and Works Manager, Knostrop Sewage Works, Leeds; (*b*) "The Disposal of Surplus Activated Sludge," by Mr. H. D. Bell, F.I.C., F.C.S., Manager and Chemist, Barnsley Sewage Disposal Works; Chairman, Mr. J. Haworth, M.B.E., F.I.C., Sewage Disposal Works Manager and Chemist, Sheffield, President of the Institute.

At 11 a.m., conference under the auspices of the Institution of Municipal and County Engineers on "The Design and Construction of Municipal Aerodromes," by Mr. T. L. Roberts, Assistant Engineer, Anglesey County Council; Chairman, Mr. E. A. Sandford Fawcett, C.B., M. Inst. C.E., late Chief Engineering Inspector, Ministry of Health, and Vice-Chairman of the Congress Committee.

At 3 p.m., conferences under the auspices of the Institute of Sewage Purification on (*a*) "Present-day Conceptions of Sewerage and Sewage Treatment," by Mr. Granville Berry, Engineering Assistant, Nelson; (*b*) "The Logical Design of Separate Sludge Digestion Plant and its Effect upon other Phases of Sewage Treatment," by Mr. A. S. Lowe, B.Sc., A.M. Inst. C.E., A.M.I. Mech. E.; Chairman, Dr. H. T. Calvert, M.B.E., D.Sc., Ph.D., F.I.C., Chemical Inspector, Ministry of Health.

At 3 p.m., conferences under the auspices of the Institution of Municipal and County Engineers on (*a*) "Private Street Works," by Mr. A. O. Mitchell, Private Street Works Assistant, West Sussex County Council; (*b*) "Vibration in Roads and Buildings," by Mr. C. H. Bradbury, A.M. Inst. C.E.; Chairman, Major L. Roseveare, O.B.E., M. Inst. C.E., President of the Institution.

SATURDAY, NOVEMBER 18TH.

At 11 a.m., conference under the auspices of the Institution of Municipal and County Engineers on "Vehicle Design in Relation to Public Cleansing," by Mr. J. E. Swindlehurst, M.A., A.M. Inst. C.E., Borough Engineer, Hampstead; Chairman, Major L. Roseveare, O.B.E., M. Inst. C.E., President of the Institution.

Letters to the Editor.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

TRADE WITH SCANDINAVIA.

SIR,—May I suggest to British manufacturers who are looking for markets abroad that they are likely to be well repaid by giving especial attention just now to the requirements of the Scandinavian and Baltic countries? The first condition of trade is the goodwill of buyers. Having just concluded an extensive business tour around that part of Europe, I am able to say that this condition, applied to British products, is everywhere in evidence to a conspicuous degree throughout the Scandinavian and Baltic countries at the present time.

Testimony to it in Finland has been given by the very remarkable demonstrations in connection with the "British Week" there. Esthonia testifies to it by buying, for the first time in its history, more goods from Great Britain than from any other country, including Germany, which for years has held first place among all countries supplying Esthonia's imports. In Norway, Denmark and Sweden I saw repeated evidence of a desire to buy British goods in preference to other imports, wherever British goods could compete upon equal terms.

One sign of the friendly disposition towards this country is the very great interest which is being taken in the Scandinavian and Baltic countries in the study of English. The records of my own organisation provide something of a barometer in this respect. At one time courses in German and French were far in excess of English courses in the Baltic and Scandinavian countries; now English easily predominates, with French second and German third. In all the Scandinavian countries I found that the study of English is being pursued intensively for both commercial and cultural purposes. In Esthonia and Latvia, instruction in English has been made part of the general curriculum in secondary schools.

These are straws which show the way the wind is blowing. I am convinced that it may easily prove a favourable trade wind for British manufacturers if they will go a little out of their way to take full advantage of it.

J. ROSTON,
Principal, Linguaphone Institute.

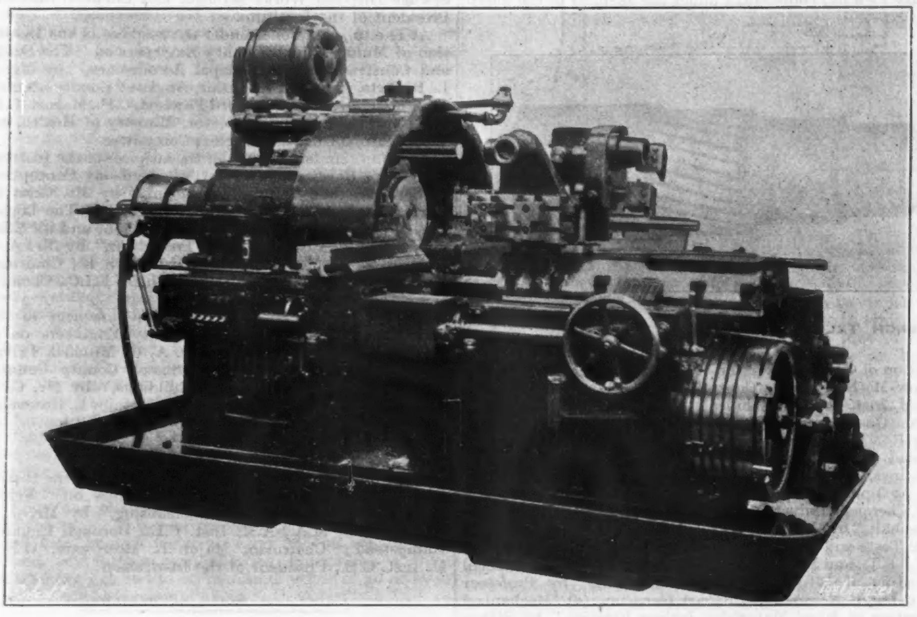
London, W.C.1, October 6th.

IT is announced that Lord Moyne, whose yacht "Roussalka," lost off the Irish coast towards the end of August, was formerly the Southern Railway Company's steamer "Brighton," has purchased the same company's steamer "Dieppe" for conversion into a yacht. The "Dieppe," which was built in 1905 by the Fairfield Shipbuilding Company, Ltd., is propelled by triple-screw steam turbines. Her measurement is 1426 tons gross, with a length of 273·5ft. and a beam of 34·8ft.

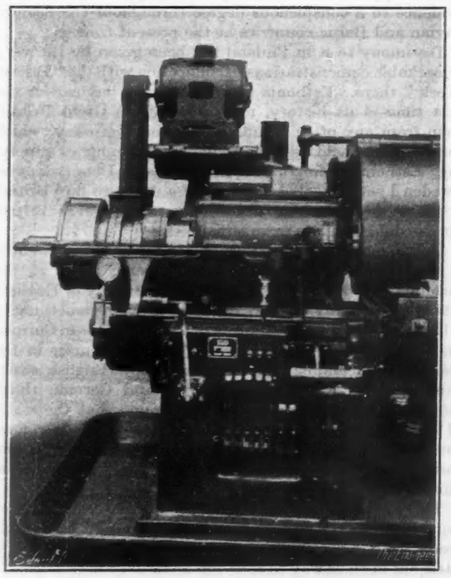
New Heavy Duty Auto-Lathe.

◆

A MACHINE designed expressly to take advantage of modern high-speed cutting alloys, with a speed range wide enough to enable all materials to be machined at the highest practicable speeds, strongly constructed to withstand the stresses arising from heavy cuts, and a new production from the works of Alfred Herbert, Ltd., of Coventry, is illustrated by the engraving below. From this engraving and the other photographs reproduced, the general design of the machine will be made clear, and we need only refer to some special details. The driving box is bolted to the back of the bed behind the headstock, and its weight is supported by an extension of the bed. As shown in the engraving, the drive is taken by multiple V belts from an electric motor mounted above on a hinged base plate carried by the driving box, but a drive from a line shaft can as easily be arranged. In all, twenty-eight spindle speeds are available, in seven ranges of four speeds each. By this means any of the seven ranges of four may be chosen as suitable for the work in hand, and automatic changing of the speeds within that range is then available. If required the changes can be made when the tools are actually cutting. The seven ranges are obtained by means of five sets of pick-off gears that connect two of the shafts in the driving box, and the four speeds in each range are obtained from two multiple-disc friction clutches.



New Heavy Duty Auto-Lathe



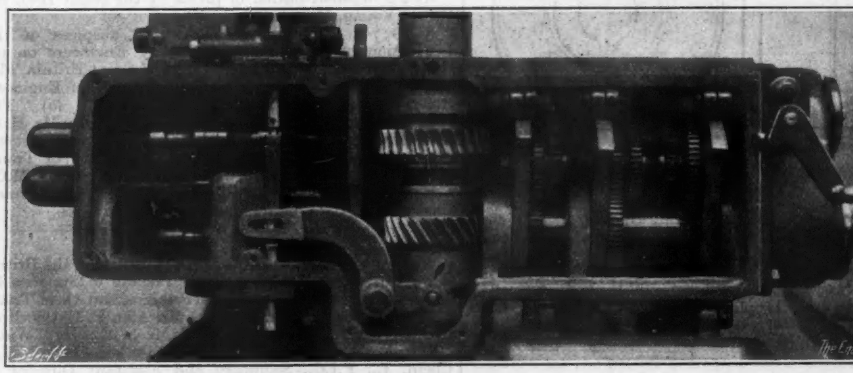
Headstock End and Speed Change Box

In addition to the automatic speed changes, it is also possible to stop the spindle automatically and re-start it. Power-driven cams in the driving box bring about the speed changes. Five bell-crank levers, each of which has a detent that retains a long plunger, are arranged in a speed change box below the headstock. Each plunger passes through the bed to the driving box, and in the normal position is just clear of one of the speed change cams. Adjustable dogs may be clamped in grooves in a drum beneath the headstock and, tripping the bell-crank levers, enable them to release the plungers which, being forced into engagement with the cams by springs, make the changes of spindle speed. The bell-crank levers have arms projecting towards the front so arranged that they may be lifted by the fingers for changing speed when setting up. It will be noticed that although only four spindle speeds are available, there are five sets of bell-crank levers. One is for starting and stopping the spindle. The lever to be seen next the bell-crank lever arms also controls the starting and stopping of the spindle.

The turret has four faces and is indexed rapidly by a Geneva motion in the slide actuated by worm gearing. After indexing it is automatically clamped firmly to its seat. Its slide is actuated by a cam drum that makes two rotations for each forward and return stroke. As the slot in the cam drum is cut like a screw which returns upon itself, the slide is moved back and forth very smoothly and steadily, even when taking heavy cuts.

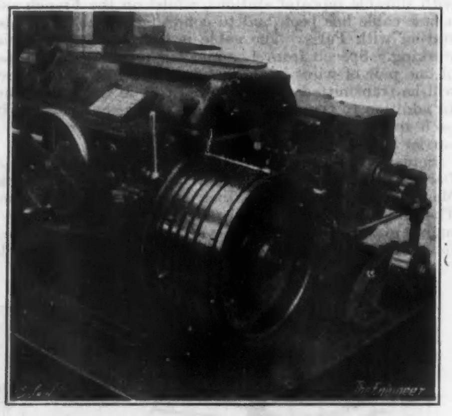
The two cross slides are quite independent. Each lower slide is a box-shaped structure, which supports the upper slide and contains the operating mechanism. The bed covers attached to the turret slide to protect the ways of the bed pass through openings in the lower cross slides. Cam drums actuate the upper cross slides, making one turn to feed them in and another to withdraw them. The length of stroke is adjustable. This automatic motion of the slides is derived from the control drum beneath the headstock. Adjustable dogs are carried in the grooves on the right-hand end of this drum. They actuate levers which, by a suitable arrangement of connecting-rods and shafts, engage clutches through which the cross slide cams are driven. At the end of the stroke the mechanism is automatically disengaged and the slide remains stationary until another dog on the control drum actuates the lever, when the slide will be withdrawn.

The feed motion is controlled by means of a continuously rotating cam in the feed box and a mechanism similar to that used for making the spindle speed changes. There are eight ranges of three feeds, each giving twenty-four feeds in all. Like the spindle speed changes automatic alterations of the range of three feeds may be made while the tools are cutting. The control drum is mounted at the end of the bed, and may be seen in one of the engravings reproduced.



Feed Box with Cover Removed

Like many other machines constructed by the same firm, considerable use has been made of anti-friction bearings in the auxiliary mechanisms of this lathe, as well as in the main components. Nearly all the high-speed shafts are carried in such bearings, and the spindle is mounted on large roller bearings specially made for the purpose. Two opposed double-purpose ball bearings take the thrusts and also part of the journal load. The question of the lubrication of all these bearings has been carefully studied, and according to the makers the arrangements are such that hand oiling with the oil can is practically eliminated. The main units, such as the driving box, headstock, and feed box, are lubricated by oil baths and pumps, while the slides and such bearings as are not in oil baths are lubricated from oil reservoirs with wick feeds or from grease nipples.



Control Drum for Feed Motion

The following table gives some general dimensions and particulars of the lathe :—

Maximum swing over bed	16½in.
Maximum swing over cross slides, using full stroke	9in.
Adjustment to headstock along bed	6in.
Adjustment of cross slides along bed	6½in.
Maximum stroke of cross slides ..	4½in.
Minimum stroke of cross slides ..	1in.
Working stroke of turret slide	10in.
Maximum distance from flange of spindle to face of turret..	27in.
Minimum distance from flange of spindle to face of turret..	11in.
Diameter of hole in spindle	3in.
Size of each face of turret	7¾in. × 5in
Diameter of base of turret	12¾in.
Diameter of tool holes	2½in.
Height of centre of tool holes above slide	$3\frac{13}{16}$in.
Diameter of single pulley	9in.
Width of belt	4in.
Speed of pulley, r.p.m.	700
Number of spindle speeds	28
Total speed range, r.p.m.	24 to 490
Number of speeds obtained by automatic changes	4
Number of feeds	24
Total feed range, cuts per inch.. ..	12 to 253
Number of feeds obtained by automatic changes	3
Horse-power	10
Speed of motor	1430
Floor space occupied	10ft. 3in. × 5ft. 6in.

The new port of Churchill, on Hudson Bay, Canada, which has been developed as an alternative route to Montreal for the export of grain, was closed for the winter on October 2nd. During the past season some 3,000,000 bushels of wheat, in eleven steamers, have been sent away from the port. It is noteworthy that the Montreal Harbour Commissioners now announce that they will pay a subsidy of $\frac{3}{16}$ths of a cent per bushel on all grain exported *viâ* Montreal. This applies to all shipments after October 1st to the end of the navigation season.

Speaking at the opening informal meeting of the Junior Institution of Engineers, Mr. K. W. Willans, in considering what effect the modern system of education had upon the widespread unemployment manifested in many directions and not least in engineering, suggested that it should be the aim of technical colleges to instil into the minds of the young the necessity of their getting to work with their hands and not thinking that their time had been wasted if they failed to get a " black-coated " job, and he questioned incidentally whether anything had had a greater effect on the production of labour troubles in this country than the black-coated ideal. He considered that the right time to go to college was between the ages of twenty and twenty-three, after a complete course of practical training.

Thirty-five Years on the Railway—and After*

By WILLIAM WHITELAW.

In these days of scientific research, to which the railway industry must always attach the utmost importance, I cannot help thinking that there is a danger of forgetting how rich an education there is to be found in the actual performance day by day of the duties of every grade in the railway service, whether in the office or out on the line.

In this connection, the question of the value of examinations as a means of finding the best candidates for certain vacancies in the railway service, and of discovering the best talent among existing employees, is worth consideration.

Personally, I have always disliked the examination system, and have rated examiners rather low in the scale of humanity, since the days when I came in contact with them, and I attach only a moderate value to its results. To begin with, there is no truth in the view that a man who, at any age up to twenty years, displays his superiority in an examination will ten years later still be the superior of someone who had scraped through or actually failed in the same examination. Constant observation has revealed to me that many of the most valuable men of thirty years of age in practical work have been drawn from those who, ten years previously, would be found to have been low down in the examination list.

My general conclusion is that examinations have a certain value, if they are wisely conducted, and are not of themselves held to be conclusive evidence either of genius or idiocy. Sometimes it would be a good thing to test the examiner by allowing those who had failed to pass an opportunity to set a paper for the purpose of ascertaining how much he himself really knew about the subject of the examination.

Railway managers engaged in the practical management of their companies would have an easier life if they were able at times to disregard the theories of the engineer, the kindly autocracy of the accountant, and the restrictions imposed by the legal adviser.

Among the questions which occur to one are such as the following—Have permanent way engineers made sufficient allowance in estimating the life of their roads for the greater weight of rails and chairs, better fastenings, more efficient creosoting of sleepers, more attention to good drainage, and the greatly extended use of stone ballast in place of gravel or ash? I can recall a short piece of line near Inverness lying very near the sea level, where drainage was difficult, which was a source of constant trouble and expense until by the adoption of stone ballast it was transformed beyond recognition. Have they made any allowance for the wonderful improvement in the balancing of locomotives, so that a locomotive weighing 120 tons or more may be much lighter on the road than one of older construction weighing much less?

Permanent way can now actually be tested from a running train and facts ascertained about matters which were formerly in the region of theory or guesswork, call it what you will!

Much of what I have said about the permanent way is also true of bridges. Only a few years ago engineers had to condemn girder bridges on mathematics, where to-day their strength can accurately be measured, and fact by displacing pure theory has added years of life to many a railway bridge.

I daringly suggest it is possible that, in the past, unnecessary expenditure has been incurred on renewal of the permanent way, because its life was estimated wholly upon theory, and that actual inspection and practical testing thereof to secure reliable facts as to its condition may well lead to definite savings in this branch of railway expenditure.

Another source of savings in connection with the civil engineering department will be found in the collection and careful inspection of all old material taken out of the line, and the separation of it into the various categories of good, indifferent, and bad, so as to make sure that no usable material ever reaches the scrap heap, especially in these days when to get rid of scrap is one of our difficult problems. I doubt if I shall ever again experience, as I once did, the sale of scrap rails at a higher price than had been paid for them when new.

A good instance of settling a problem by practical experience instead of by theory, was found in certain locomotive trials which were carried out in 1910 on the London and North-Western line between Carlisle and Preston. I was anxious to find out by actual experiment what were the respective values of a six-coupled and an "Atlantic" engine on the Waverley route of the North British Company, as I was wondering if the North British "Atlantic" was the best possible type for that route, and the intention was to run trials between the North British "Atlantic" and the London and North-Western six-coupled engine between Carlisle and Edinburgh. This intention had to be departed from as it was found that the dome of the London and North-Western engine was rather higher than was safe for running under one or two bridges on the Waverley route, and the change was accordingly made to the line between Carlisle and Preston. Each engine hauled the same train in both directions, the weight of the train being 284 tons. The L.N.W. engine was No. 1483, named "Redgauntlet," weighing about 103 tons with six-coupled wheels 6ft. 3in. in diameter, an axle weight of 18½ tons, and the boiler having a pressure of 185 lb. per square inch. The "Atlantic" engine was No. 881, named "Borderer," weighing nearly 120 tons with 4-4-2 arrangement of wheels, 6ft. 9in. in diameter, an axle weight of 19½ tons, and a boiler pressure of 190 lb. per square inch. Neither engine was fitted with a superheater. On the up journey, "Redgauntlet" took 110½ min. and "Borderer" 109¾ min. On the down run, "Redgauntlet" took 102½ min. and "Borderer" 102 min. These are the times given on the London and North-Western report on the trials, and show no difference as regards timekeeping. The most interesting point, however, in the test was that, contrary to what might have been expected, the six-coupled engine took 10 min. to climb the hill from Tebay to Shap Summit, while the "Atlantic" accomplished the climb in 9 min. This was wholly due to the "Atlantic" engine having been able to pass through Tebay at 62 m.p.h. against the speed of only 57 in the case of the six-coupled engine; as a matter of fact, the last half-mile threatened to see "Borderer" come to an ignominious stop, which was averted only by the frantic efforts of the fireman. These efforts were reflected when the coal consumption came to be reckoned up. The consumption of "Redgauntlet" was 58 lb. per mile, and that of "Borderer" 71 lb. The outcome of the trials was to indicate that each company had, apart from the coal consumption, the engine most suitable for its road, the 4-4-2 wheel arrangement being more suitable for the many more severe curves on the Waverley route than are to be found between Carlisle and Preston. The trial, of course, opened the North British eyes to the extravagance of the coal consumption of their engine, and that question was tackled with no small success by Mr. Reid, the locomotive superintendent of the company, though he could never reduce the consumption to anything like that of the L. and N.W. engine. Locomotive science has made such progress since these days and the greatly increased weight of trains has altered the problem which then had to be decided; to-day, the "Pacific" reigns supreme on the Waverley route.

Perhaps there is no more important work in the whole range of railway management than the compilation of the time-table. I attach more importance to the punctual working of both passenger and freight trains than to the running of a few trains at spectacular speeds, or for long distances without a stop, however successful these may be in securing headlines in the daily Press. Nothing gives passengers so much satisfaction or attracts them so much to a route as the regular punctual arrival of trains at their destination.

A frequent cause of bad train working really begins, curiously enough, with the appearance of a new and more powerful engine. All goes well for a few weeks when the engine is more than master of its load; then someone in the superintendent's department surreptitiously adds another vehicle or two to the train, and then it is found that the train is too long for some platforms with the result of introducing the greatest enemy of punctuality—a double pull-up. Nothing but a study of all the actual facts so as to make certain that the running staff are not being asked to do the impossible will permit of a high degree of punctuality being secured and maintained. What after all, is the control system? It is just applying judgment to the actual facts as they exist hour by hour in the daily running of trains; it is the highest form of practical train working, and is a most valuable daily source for the supply to the superintendent of the facts about his train running which he would otherwise never obtain in time to be of any great use.

Thus, while one starts the compilation of a time-table with the theory that a train of given weight can run a certain distance in a certain time, it is the actual daily practical experience on the footplate, in the guard's van, on the station platform, and in the shunting yard that renders possible the really punctual running of the whole service.

One might spend an hour or two speculating upon the theory of the Railways Act of 1921, and the practical results which have flowed from it. The main theory of the Act was that an economic basis for the amalgamated railways would be found by stating the remuneration to which owners of railway capital should be entitled, the appointment of one Tribunal to fix wages and conditions of labour and another to ascertain and fix the rates and fares which would, under efficient management, provide the cost of labour and the proper remuneration of capital.

The latter Tribunal has year by year given the companies its certificate of efficient and economical management, but has found its duty of fixing rates and fares for the proper remuneration of capital in the face of the cost of labour, as fixed by its sister Tribunal, to be impossible of discharge. The Act had assumed that there would always be traffic awaiting conveyance at the necessary rates and fares, and Parliament does not seem to have given any consideration to the situation which has actually arisen, in which the traders are clamouring for lower rates and greater rapidity in conveyance, while even at the existing rates the economic position aimed at has not nearly been reached. Here, certainly, is an instance of the breakdown of theory before the irrefutable facts which have dominated the railway situation for the last ten years. Another theory of the Act, which, I think, has proved to have been sound, was that only by a policy of amalgamation could the railway system over the whole country be maintained. I have little doubt that, but for the Act, some of the old railway companies would have ceased to function; probably one or two of them could not recently have earned their working expenses. Even amalgamation has not been able to save some branch lines from partial or total closing down, and I daresay we shall see further closing down yet.

During the last thirty years I have been doing what little I could to overthrow the era of frantic competition and to promote co-operation in the policy and management of the railways; as I look back on those years I realise how little was accomplished until recently.

Has the amalgamation policy of the Act of 1921 been a success? is a question often put to me. To find the answer one must, of course, make an estimate of what the position of the former companies would have been to-day, and I have already indicated that, in my opinion, disaster would have fallen upon some of them. There is a tendency to denounce the whole amalgamation policy merely because, after ten years, three of the four companies have failed to earn any dividend on their Ordinary Stocks; those who set up as critics of the policy must tell us what would probably have been the dividend position of the companies had they continued to occupy their respective independent positions as in 1913; until they do so, I think their criticisms require no answer.

I am by no means satisfied that the fullest possible co-operation has yet been established between the companies of to-day; there is room for wider and more complete systems of pooling than have yet been agreed to. Nevertheless, there is an amount of co-operation far beyond anything that could ever have been attained under the organisation of 1913, and I am hopeful that future years will see a constantly increasing growth of pooling policies and co-operative working.

The era of competition expired with the advent of the war. No single company, and, I am sure, no railway manager ever suggested that during the war, when the national interest stood paramount, the railways could be conducted except under a single command, and with a common purse out of which should be disbursed to each company a proportion of the whole receipts, in no way varying with the route of the traffic. Just as during the war the traffic was routed in accordance with the interest of the State, as the supreme trader, by the Executive Committee, so to-day there is only one sensible method of routing traffic, and that is by the cheapest and quickest route in the fewest possible number of vehicles, and with the least possible amount of shunting, thus serving the real interests of the trader, the traveller, and the railway system as a whole. Every hour that a traffic officer spends in devising how to divert a wagon from its natural route is an hour lost to economic transport.

Perhaps I shall find few supporters for the policy of complete abolition of competition between railway companies, but I am comforted by the fact that time is on my side, and the knowledge that the young railwaymen of to-day are not being educated in the school in which the older among us were brought up, and which taught that the highest efficiency in railway commercial policy was to be found in the unrelenting plan of playing the not very exalted game of Begger-my-neighbour.

The essential principle of conducting railway traffic ought to be the adoption of such a complete system of pooling as would put it out of the power of any railway company to earn profit by competition with another; plenty of work can be found for the die-hards of competition by concentrating their efforts on dealing with the new competition in the transport world of to-day.

One of the most vital points in the administration and management of very large railway companies is wide decentralisation. With such decentralisation I do not think the total disappearance of competition among railway companies need have any terrors either for traders or for the travelling public. On the contrary I believe that all interests affected by railway transport in this country have nothing but gain to expect from the extension of pooling systems and the further unification of railway administration.

I shall perhaps be told that I am advocating the establishment of a monopoly! Well, I do not deny it! But it would be a regulated monopoly under the provisions of the Railways Act of 1921, which are ample to prevent exploitation, there being effective control of rates and fares by an independent Tribunal, and a provision by which any profits secured beyond the standard laid down must, to a large extent, go to the reduction of charges.

When I became chairman of the North British Company I realised that the work was totally different to what it had been at Inverness, and that any very close attention to detail would render the discharge of the chairman's duty impossible. A further surrender of detail was obviously necessary when seven companies were amalgamated to form the London and North-Eastern Company, and thus my varied experience of the chairmanship of three companies, each of the latter two infinitely larger than its predecessor, taught me that as a company increases in size, more and more decentralisation of administration is essential. As in the administration so in the management; the spreading of the responsibility becomes more and more necessary as the task increases in volume and complexity, but with adequate decentralisation there seems to me to be hardly any limit to the size of a company which can be put under one control. It is all a mixture of personal control and wide diffusion of responsibility throughout the geographical area served by the company.

An apt illustration of what I mean is found in that delightful nonsense verse written, I think, by Sir Theodore Martin, whom all railway directors, managers, and solicitors of the last generation will remember, entitled, "The Massacre of Macpherson." It is in the Highland dialect;:

> Fhairshon had a son
> Who married Noah's daughter,
> And nearly spoil'd ta flood
> By trinking up ta water;
> Which he would have done,
> I at least pelieve it,
> Had ta mixture peen
> Only half Glenlivet.

I for one would have no fear of the unification of even all the railways provided that the concentration of the "Glenlivet" was suitably countered by the water of diffusion in the administration and management of the whole. Probably it will be said that that would be just the penultimate step to nationalisation.

The statesmen of the future will be well advised not to be frightened by a name, even though it does not "smell sweet." National management of the railways would prove, I do not doubt, ruinous to both passenger and industrial transport, but national ownership, with management completely divorced from political influence is not impossible, and cannot be dismissed from consideration for all time because of the prejudice attached to the name of nationalisation.

Following a meeting of local authorities in Liverpool, held some time ago with the object of forming an Advisory Regional Smoke Abatement Committee for Merseyside and South-West Lancashire, a similar conference has taken place in Newcastle-upon-Tyne. This conference, convened by the Newcastle Public Health Committee, has also been successful, and it has been agreed to form an Advisory Regional Committee for Northumberland and Durham.

South African Engineering Notes.

(By our South African Correspondent.)

Electricity Schemes.

The Kroonstad Town Council has decided to proceed with a £60,000 electricity scheme which will involve the installation of an entirely new generating plant and the replacement of direct current by alternating current. The scheme was approved by the ratepayers two years ago, but the Council would not put it into commission, owing to the fact that money was too dear. Somerset West ratepayers have sanctioned the raising of a loan of £4000 for the purpose of extending the electric lighting installation of the town and providing two new sub-stations. The Fransch Hoek Municipal Council has completed negotiations with the Electricity Supply Commission for a supply of electricity. The work of erecting a transmission line and distribution mains is to be started immediately. The Lichtenburg Town Council is considering the installation of a new and up-to-date lighting scheme for the town; the proposals are for a new oil plant, developing alternating current, to cost about £12,000. The town of Gwelo is going into the question of additional plant, the present installation being barely able to cope with the increasing demands. An electric lighting scheme for the new capital of Northern Rhodesia, Lusaka, has been agreed upon, and instructions have been given to proceed with it as early as possible. The City of Cape Town invites tenders for the supply and delivery to Dock-road power station of an alternator set. East London contemplates spending £50,000 in extending its electrical installation. Bloemfontein City requires £20,000 for the installation of additional cables, transforming apparatus, meters, &c. An up-to-date all-electric station and control tower is to be built at the Rand airport at Germiston. Outshoorn town is asking for a loan of £31,000 to transform its existing power system to one of alternating current, also for new generating plant with the necessary boilers, &c.

Subsidising Italian Vessels.

Great astonishment was created in commercial and shipping circles by the agreement of the Union Government to subsidise two Italian shipping lines to the extent of £150,000 per annum to start a service between Genoa and Africa, in addition to two Italian lines at present running. For the subsidy the lines undertake to run four big liners of 20,000 to 24,000 tons at an average speed of 18 knots, and which will do the trip between Cape Town, Marseilles, and Genoa in 14 days 15 hours—the Union-Castle Mail steamers from London to Cape Town take over 16 days. The idea is that these Italian liners will carry cargo from Italy, France, Switzerland, and other countries, even Jugo-Slavia, Rumania, Austria, Poland, &c. The service will call at Ludentz, Walvis Bay, Lobito, Matadi, Lagos, Freetown, and Dakar. The Union Government further expects to extend trade with Kenya, Tanganyika, Aden, Egypt, Nigeria, and Belgian Congo, as the lines will run *viâ* the East and West African ports. It does not seem that the very small trade done by the Union with East and West Africa warrants any such subsidy, and the prospects of increasing the present trade seem small, as all the places named are already well served by British lines. The granting of the subsidy came as an entire surprise to commercial and shipping firms throughout the Union, and is regarded as a distinct blow to British shipping prestige. The whole matter will undoubtedly be thrashed out when Parliament meets. The only tangible claim made by the Minister of Commerce and Industry, who is responsible for the agreement (Mr. A. P. J. Fourie), is that the Italian companies will purchase S.A. coal and ships' stores in the Union to the amount of about £100,000 per annum. This is doubtful, in view of the extent to which oil is superseding coal for bunkering. It would appear that the Italian Government has striven hard to get this agreement accepted by the Union Government, and is subsidising these new lines—as far as running to S.A. is concerned—to the extent of £300,000 per annum. The Italian Government will also give S.A. preference when placing its annual contracts for beef for the Italian Army. The Minister of Commerce has explained that the Union Government is concerned at the small trade done by this country with East and West Africa, and believes the new arrangement will increase it, but the question is being asked why was the agreement come to with Italian companies without giving the British lines an opportunity of stating what they would be prepared to do for a subsidy of £150,000 per annum. The representatives of British firms state that they were never approached, and never heard anything about the matter until it was published in the Press. They also state now that they would have given what the Union Government required for a much smaller subsidy. Britain's re-export trade will suffer by the new arrangement.

Railway Electrification.

Sanction has been received at Durban from the Railway Board for work to begin immediately on the electrification of the railway track from Daimana to Harrismith, and it is anticipated that trains will be running over the line before the end of next year. The Administration's engineers have departed widely from precedent in many directions, and the economies contemplated will save many thousands of pounds. With the exception of cross-arms for the transmission line masts, everything will be made from scrap metal, and the main feature of the work is the total elimination of the enormous cost of running transmission lines across the country by the simple expedient of lengthening and strengthening the ordinary overhead equipment track masts. This will probably be the first occasion in the history of electric railways that so enormous a voltage as 88,000 volts has been carried on normal overhead equipment masts. The high-tension line on the Cato Ridge section of the line is 33,000 volts. The transmission current will be carried well out of reach of the overhead equipment, and tapped into sub-divisions, at which it will be transformed and converted to 3000 volts direct current. This will eliminate the enormous cost of fabricating transmission line masts to run across the country. Another outstanding feature is the departure from ordinary practice in the mast foundations. Instead of making concrete foundations on the spot, specially designed, pre-cast reinforced sleepers will be made at the Daimana depôt and set in position underground to receive the masts, which will simply be bolted into position. There will be a great saving by doing this.

Table Mountain Cableway.

The Table Mountain aerial railway, or cableway, has now been running for over three years, but although fairly well patronised it has certainly not been the success which the promoters of the enterprise anticipated. This is, of course, due to a great extent to the depression which had started before the cableway was well launched, and has continued up to the present, when it shows signs of lifting. When prosperity returns the cableway should speedily wipe out the loss that has been made and earn good profits, for there is no doubt that the view from the station on the top of Table Mountain is very wonderful, and will be an irresistible attraction to visitors from overseas, and just as much to residents in Cape Town and the Cape Peninsula. The span of the Table Mountain cableway is 4000ft., with a gradient of 17·5 per cent. The tension of the carrying cable is kept constant by counterweights at the lower station, and it is anchored at the summit by means of a concrete drum. This cable, on which the "cages" are suspended, is 1⅞in. in diameter and consists of 133 strands of wire rope. The cable is capable of bearing a weight of 120 tons. The cages weigh approximately 3 tons each. Each is suspended from the cable by eight rubber-tired wheels, and as it moves an automatic oiling system prevents rust and minimises friction. A 75 H.P. electric motor in the upper station provides the necessary haulage power, which is small, owing to the fact that the two cars connected to the same hauling cable are perfectly balanced. In addition to the carrying and hauling cable, an auxiliary cable is provided in case of emergency. This is connected to a separate motor of 35 H.P. There is also a 45 H.P. auxiliary petrol motor. The driver of the haulage machinery in the upper station has a clear view of the whole cableway, and can stop the machinery at a moment's notice. The conductor in each car can similarly bring his car to a stop in midair. When the ascending car is about 60 yards from the upper station a warning bell rings, and the controller at his observation post slows the car down to half speed. If, however, through negligence or emergency, he omits to do this, the car comes to a stop automatically 50 yards from the station. Telephonic communication between the two stations and the cars is effected by means of the haulage and carrying cables themselves.

New Railway Works.

A total sum of £4,376,662 has been allocated for new railway works for the year ending March 31st, 1934. Of this, £342,120 is for the construction of new lines, £1,034,867 for new works on existing lines, and £114,670 for the harbours. The balance is for various works and for new rolling stock. Railway traffic is reviving so rapidly that much new rolling stock and locomotives must be obtained. For the first four months of the current financial year there has been an increase in the railway receipts of nearly £1,000,000, compared with last year, the respective figures being £7,789,985 and £6,848,126. That the improvement continues is shown by the fact that the revenue for the week ended September 2nd was £486,181, which is more than £60,000 higher than the earnings during the corresponding week of last year.

BRITISH STANDARDS INSTITUTION.

All British Standard Specifications can be obtained from the Publications Department of the Institution at 28, Victoria-street, London, S.W.1. The price of each specification is 2s. 2d. post free, unless otherwise stated.

LIGHT ALLOY CASTINGS FOR AIRCRAFT PURPOSES.

The following new and revised British Standard Specifications for Light Alloy Castings have recently been published by the British Standards Institution :—

3 L 5.—Aluminium-Zinc-Copper Alloy Castings.
3 L 8.—12 per cent. Copper Aluminium Alloy Castings.
4 L 11.—7/1 Aluminium Alloy Castings.
2 L 24.—"Y" Aluminium Alloy Castings.
L 33.—Silicon-Aluminium Alloy Castings.
L 35.—"Y" Aluminium Alloy Castings (heat treated).

The principal revision consists in the substitution of test samples cast in dry sand moulds for those cast in chill moulds. The method of casting the test samples, the dimensions of the dry sand moulds and the tensile test figures required are specified. Corresponding tensile test figures which may be expected from the test samples if cast in chill moulds as formerly specified are added for information only.—Copies of these specifications can be obtained from the Institution, 28, Victoria-street, London, S.W.1, price 1s. 2d. each post free.

SAMPLING OF COAL.

No. 502—1933. This specification covers the new British Standard Method for the Sampling of Large and Run-of-Mine Coal. Hitherto the methods used have been somewhat empirical and, as a consequence, a high factor of safety has been employed resulting in very large gross samples. The British Standard Method follows in general principles the theory that was adopted as a basis for the Sampling of Small Coal, and recommends minimum sizes of samples based on the theory of errors, in which the size of the sample is directly related to the heterogeneity of the fuel and the degree of accuracy required. As a consequence, it has been found possible in the specification to recommend the adoption of much smaller sizes of gross samples than those previously taken.

The specification lays down the size of gross sample to be taken and the methods of collection and reduction to be used for coal from chutes, conveyors, and wagons, both riffle and the hand methods of reduction being described.

The Committee is unable to recommend a standard method for sampling from heaps that would be generally applicable, having due regard to the possible heterogeneous nature of the heap. A full account of the experiments and theoretical considerations which form a basis for the specification is included as an Appendix.

CREOSOTE FUEL.

No. 503—1933. This specification provides for creosote produced as a distillate of coal tar and it must be free from admixtures of petroleum oils, or undistilled crude tars. In view of the importance of maintaining fluidity it is required that the oil shall be free from organic acids, sediment or other impurities likely to choke the burners, and attention is also called to the fact that with some grades of creosote that are covered by the specification it will be necessary to provide warm storage and heated pipe lines. The specification includes requirements for the physical properties of the material, such as specific gravity, viscosity, water content, matter insoluble in benzole, fluidity, flash point, ash, and calorific value. Details as to the method by which the tests for the determination of these requirements are to be carried out are given in appendices to the specification.

PERSONAL AND BUSINESS ANNOUNCEMENTS.

The Becco Engineering and Chemical Company, Ltd., has moved to Effingham House, Arundel-street, London, W.C.2.

William Firth and Co. moved on September 30th from 8, Hillary-place, Leeds, to 1, Lifton-place, Leeds, 2. The same telephone number and telegraphic address.

Mr. G. H. Brooke, assistant to the managing director of C. Akrill and Co., Ltd., West Bromwich, was on October 3rd appointed Secretary of the Staffordshire Iron and Steel Institute.

W. and T. Avery, Ltd., Birmingham, announce that Mr. P. H. Mills has been appointed managing director to succeed the late Sir Gilbert Vyle. Mr. Mills joined Avery's in 1919 and was appointed general manager in 1924. He joined the Board of Directors in 1927.

Herbert Terry and Sons, Ltd., Redditch, announce that Mr. J. A. Darby has been appointed sales manager at Redditch. He has been in the service of the firm for eighteen years, eight of which were spent in the eastern counties, where he will be succeeded by Mr. R. H. Chambers, who has been with the firm since 1919, and since 1927 has represented the firm in the North of England.

CONTRACTS.

Richard Crittall and Co., Ltd., of 43, Bloomsbury-square, London, W.C.1, have received an order for the destruction of the old chimney stack in Carnaby-street, London, W.1, a landmark in the West End belonging to the St. James and Pall Mall Electric Light Company, Ltd., and the equipment of the building with electric heating. The electrode boilers will be supplied by Bastian and Allen, Ltd., of 12 and 14, Church-road, Hanwell, London, W.7.

C. A. Parsons and Co., Ltd., Newcastle-on-Tyne, have received from Dominion Boxboards, Ltd., of Toronto, an order for an electrical generating set comprising a pass-out steam turbine coupled through gearing, both to a 1500-kW alternator and exciter and to a 250-kW direct-current generator. The turbine will run at 5500 r.p.m., and the electrical machinery at 1500 r.p.m. The set, which is of the "Uniplane" type, requiring no basement, will supply both three-phase current at 600 volts and direct-current at 500 to 70 volts.

Modern Factory Design.—Professor Maier Leibnitz, of the Technical High School in Stuttgart, gave a lecture on October 5th, at the headquarters of the British Steelwork Association on Modern Factory Design to a representative gathering of engineers. Professor Leibnitz was able to meet members of the Steel Structures Research Committee which was set up by the Department of Scientific and Industrial Research in co-operation with the British Steelwork Association, and he dealt with the direction of recent German research work in factory and steel-frame building construction. This research, he said, has brought to light many interesting advances, notably in the plastic theory of design, which has lead to a more rational utilisation of the elastic properties of steel construction. This was illustrated by tests carried out on continuous girders, which show that the stress transfer due to plastic qualities of steel have not hitherto been definitely evaluated. Professor Leibnitz illustrated this lecture with very notable examples of steel factory design, and dealt with the conditions which are essential to secure the best lighting conditions.

"Mavor and Coulson" Travelling Studentship.—The Council of the Institution of Mining Engineers has accepted a generous offer, made by Mavor and Coulson, Ltd., of Glasgow, of a sum of £300 for a further year, for a Travelling Studentship, which must include Canada or the United States of America in the itinerary of the selected candidate. The award will be made by the Council of the Institution on the recommendation of a Committee of Selection, and will be open to British subjects over twenty-two years and under thirty years of age who are Student Members, Associates, or Associate Members of the Institution of Mining Engineers, and who have graduated in Mining at a University, or hold the Diploma in Mining of an approved College or School of Mining, or who otherwise satisfy the Council that they have had a sufficient scientific training, and, in addition, must have had at least two years' underground experience in a colliery. The successful candidate will be required to devote one year to the special study by underground investigations of the methods practised in the actual mining of coal and in the transport of coal from the face to the main mechanical haulage; to follow a pre-arranged itinerary specifying the collieries to be visited, subject to the condition that not more than one month shall be spent at any individual colliery; at least one month shall be spent in Canada or in the United States of America; and a candidate who knows a foreign language may be required to spend not less than two months on work on the Continent of Europe. Full particulars may be obtained from the Secretary of the Institution at Cleveland House, 225, City-road.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

The Scrap Position.

The advance in the price of scrap iron and steel has been one of the outstanding features of the markets this year. For instance, basic steel scrap which at about this time last year was quoted at 35s. per ton, is not now easily obtainable at 42s. 6d. Sellers of most classes of scrap are reluctant to enter into heavy engagements, as they are finding it difficult to obtain supplies. Upon this subject, Mr. Joseph Ward, the chairman of Thos. W. Ward, Ltd., made some interesting remarks at the recent annual general meeting of the company. He pointed out that for a considerable time his firm had been warning the steel companies that the ridiculously low prices for scrap could not last as soon as there was a moderate increase in trade. It was the most important raw material in steel production, and could not be held down indefinitely below its economic value compared with pig iron and other raw materials. The firm had urged the importance of adopting some scheme to retain in this country the large weight of obsolete tonnage which was being sold abroad. As the steel works were at that time getting ample supplies of scrap at their own prices, they neglected to take any action. In the same speech he pointed out that the cheapness of scrap had had a serious effect upon shipbreaking and works dismantling operations, as to sell scrap at the low prices then offered by steel manufacturers, ships could not be purchased to allow for the heavy labour cost of demolition and transport, whilst at the same time there has been little inducement for owners of obsolete plant to put it on the market. Mr. Ward's remarks are appropriate to the position existing at the moment, as it is generally understood the steelmakers have an understanding amongst themselves as to the prices they will pay for their scrap supplies. These do not agree with sellers' views and something in the nature of a tug-of-war is in progress between the two sides of the market.

Pig Iron.

ALTHOUGH most of the large consumers of pig iron have covered their requirements a fair way ahead, some, in fact, into the first quarter of next year, there has been some rather brisk buying in this market during the past few days. Previously, there had been a spell of listless trading, but the firm tone of the market as a result of the rising tendency in the cost of raw materials like coke and ore has stimulated buyers to fill even their small needs in case an advance in pig iron prices takes place. On the North-East Coast it is stated that a proportion of the stocks remaining in the makers' hands have been sold, and as only two furnaces are producing Cleveland iron the output is not equal to the consumption. As a result the producers are less inclined to cut prices for export business and are not pressing sales in some of the outside districts. Current prices for Cleveland No. 3 foundry are 62s. 6d. d/d Teesside and 2s. more to consumers in the North-Eastern area; 65s. 3d. d/d Glasgow, and 62s. 3d. d/d Falkirk. Exports of pig iron from the Tees during September reached 13,862 tons, compared with 12,848 tons during August. Of this total only 4925 tons went to foreign destinations, compared with 4481 tons in the previous month. In the Midlands business has been somewhat irregular, and for the most part has consisted of small parcels. The demand has been principally from the light castings industry, but orders from the general engineering trades seem to be increasing in number and tonnage. Judging from the way the month has opened in this district it seems probable that the turnover for October will be in excess of that for September. In Scotland another furnace has been started up on hematite at the Govan Works, bringing the number of furnaces in blast in Scotland to nine. Of this total four are producing foundry, four hematite, and one basic iron. Business in East Coast hematite has been on a good scale for some time, and after showing considerable firmness prices have definitely advanced. The producers are unwilling to sell far ahead at the new prices, although, in some cases, buyers have offered contracts for delivery over the greater part of next year. The general price now may be called 60s. 6d. for No. 1 and 60s. for mixed numbers, f.o.b. and f.o.t.

Semi-finished Steel.

The chief characteristic of this market is the increasing tendency for quotations to advance. This is not surprising since practically all the British steel works producing blooms, billets, and sheet bars are well off for orders, and specifications are coming forward at a satisfactory rate. The competition experienced from the Continent has scarcely affected the position of the home producers. The Continental works are prepared to make special prices for the British market, dealing on its merits with each transaction, but, generally speaking, the quotations received cannot have been satisfactory to the foreign sellers. Orders amounting to several thousand tons go abroad each month, but the total trade in this material is, of course, very much smaller than before the import duties were imposed. In the inland markets Continental semis have only a restricted sale. Even in South Wales, where the Continent formerly sold considerable quantities of billets and sheet bars, the British works are in such a good position that they have been able to raise their quotation for sheet and tin-plate bars from £4 15s. d/d to £5 d/d. In this they have followed the example of the makers in other districts who, for some time past, have asked a premium of 5s. to 7s. 6d. on the official minimum prices of £5 for 500 tons and £5 7s. 6d. for 100 tons or less. It seems likely that before long the advances will be made official. Some makers, however, are reluctant to increase the official prices, although they no longer represent the figure at which business is being done.

Finished Materials.

The market in manufactured iron and steel is still irregular if the business passing and the works operations in the different districts are compared; but, on the whole, conditions appear to be generally improving. This is particularly noticeable on the North-East Coast, where preparations are being made to increase production. The steel works have a considerable amount of constructional work in hand, and the volume of general merchant business is expanding. The lack of good specifications from the shipyards is a disappointing feature of trade on the North-East Coast. In the Midlands most of the business passing has been on the small side; but the works are well employed and specifications against old contracts are coming in regularly. A considerable volume of business is passing in small bars, which are not subject to price control, and prices show an advancing tendency. For this reason probably a number of contracts have been placed lately for forward delivery, consumers evidently wishing to cover their requirements before prices appreciate further. A fair amount of business has gone to the plate mills lately, which were beginning to find conditions rather dull. There is a poor demand for boiler plates at the general quotation of £8 5s. For ship and tank plates the official quotation is £8 17s. 6d. The recently increased business in sheets has been well maintained, particularly for black sheets of the thicker gauges. For the first time this autumn some improvement has been noticeable in the demand for colliery materials, although the business is still far below the normal for this period of the year. In the Sheffield district several big contracts are in hand, and the general run of business is fairly satisfactory. The demand for stainless steel sheets is growing and the motor industry has been taking a considerable tonnage of alloy steel sheets. Export trading remains on the light side, but recently some fair business in tires has been taken from overseas markets. In South Wales business is fairly active, and although orders for tin-plates have fallen off in the last few weeks deliveries against contracts have been well maintained. Engineering firms in South Wales are moderately well employed, and are taking a fair amount of steel. It is noteworthy that the Whitehead Iron and Steel Company's works at Newport have lately found it necessary to work over the week-end. This company has secured a considerable volume of business in recent months in small bars and strip on home and overseas account.

The North and Scotland.

The activity in Lancashire is not so pronounced as it was a few weeks ago, but the lull is regarded as being of a temporary character. Consumers persist in purchasing their iron and steel requirements in small parcels. An active demand still exists for steel bars for bright drawing purposes, and it is probable that a considerable amount of business which used to go to America has been diverted by the duties to British works. Re-rollers of small steel bars are also meeting with a better call for their products than of late, and business in alloy steels has been well maintained. General engineering concerns are not really well off as regards orders, and their buying is spasmodic; but on the whole the demand from this source is increasing. It is unfortunate that the locomotive builders and the boilermakers continue to find conditions difficult, and as a result their call for boiler plates and similar materials is on a poor scale. In Scotland rather more cheerful conditions rule, and it is pointed out that if the Scottish shipyards are still passing through a period of depression they have been far busier than the shipbuilders in other districts in Great Britain. This year the total number of vessels launched at Scottish yards reached thirty-three, aggregating 49,000 tons. A number of the engine shops on the Clyde are busy and Wm. Beardmore and Co., Ltd., state they have more work in hand than for some years past. It is expected that the Orient Line will shortly ask for tenders for a new liner, and that the contract will be placed either on the Clyde or at Barrow. Nevertheless, at the moment the position at the Scottish steel works might be better, and contracts have been worked off quicker than new business has been placed. Until the shipyards are much busier, the demand for plates and sections cannot be satisfactory. On the North-West Coast the works are busy. The mills at Barrow and Workington are well employed on railway material and hoops, but fresh contracts would be welcomed.

Finished Iron.

Most of the British works engaged in producing bar iron have definitely improved their position during the past week or two, and business in this department seems likely to increase as the autumn demand develops. In the Midlands orders for the higher grades of bars are increasing in number, but business is principally for bars of the commoner qualities. Marked bars are quoted at £12 at users' works, and Crown bars at £8 10s. to £9 10s. Nut and bolt iron is quoted at £6 15s. to £7 10s., and as Continental material of similar quality is offered at about the same price, most of the business is going to home manufacturers. Business in Staffordshire marked bars has been on a more satisfactory scale of late; but there is still much idle plant. In Lancashire also there seems to be a revival in the demand for finished iron. Lancashire Crown bars are quoted at £9, with best bars at £9 10s. In Scotland the bar iron works are moderately well employed. Recently few contracts have been placed for forward delivery, but there has been a steady week-to-week demand. A certain amount of business has been done in iron for socket and fitting purposes. Most of the orders which have come to hand are for small parcels of a miscellaneous character; but now and again some fair-sized orders are taken for iron for railway purposes. Business in horseshoe iron remains steady, but shows little sign of expansion.

Ferro Alloys.

The market for ferro-alloys has revived of late although there is still much room for improvement. Most buyers have covered their requirements, and there is again a noticeable tendency in the market for transactions to be limited to hand-to-mouth quantities. Business in ferro-silicon has been on a good scale recently, but at the moment consumers appear to be in a hesitating mood. In ferro-chrome buying has fallen off slightly, but prices are still retained at recent levels. At the same time there are expectations that the prices of this alloy will be increased in the near future. The situation in the market for tungsten is interesting, and difficulties are experienced in obtaining adequate supplies of ore, owing to the attitude of the Chinese producers who, as reported recently in these columns, are restricting the quantities they offer. The price of this alloy has advanced several pence per pound since the beginning of the year, and if the ore position does not ease shortly further increases are expected. It is perhaps a good sign that some of the larger producers have covered their requirements up to and beyond the end of the year. The demand for cobalt is only moderate. Until recently a fair business was transacted in this alloy with the manufacturers of magnet steel, but this has now declined. The price of silico-manganese has become firmer, but at the same time buying has slackened and users appear to watch the market.

Copper and Tin.

The electrolytic copper market after a spell of moderate activity has again slipped back into a listless condition. This market is particularly sensitive to outside influences, and the progress of events in America and political affairs on the Continent have been adverse to an upward movement. Consumers in Europe have sufficient copper to carry on with, and prefer to buy from hand to mouth, and on a declining market rarely commit themselves far ahead. The shrinkage in values has not been noticeably heavy, but it has been sufficient to create a certain amount of nervousness amongst buyers. This, in turn, has been reflected in fresh weakness in the market. A short time ago the quotation for electrolytic went up to £39 5s.; since then it has eased to £37 10s., and at times producers have pressed forward sales. Latterly there has been some speculation in electrolytic copper, and dealers have bought fair quantities, the narrow margin between standard and electrolytic probably encouraging them to undertake these operations. Business in the standard market also has been on only a moderate scale, and prices have shown a weak tendency. Some of the selling in this market was probably due to speculators taking the view that the standard price was more likely to recede than the electrolyte was to advance. . . . . Lethargic conditions have developed in the tin market after the sharp burst of activity which followed the publication of the September statistics. Buying for industrial purposes has been light, both from America and from the Continent, whilst the tin-plate works in South Wales have not shown much interest in the metal. Heavy shipments of tin were made to the United States last week, and stocks in this country were reduced by over 1000 tons. It is expected that the October statistics will show a further decrease in the supplies.

Lead and Spelter.

Steady conditions have ruled in the lead market this week, and prices have fluctuated within a narrow margin. The buying which took place at the beginning of the month was not maintained, and the demand from consumers is still on a rather disappointing scale. The fact, however, that the manufacturers of lead products generally, and those of lead pipe and sheet in particular, are producing at a high rate is a satisfactory feature of the position. No doubt most of these consumers have stocks to draw upon, but at the current price the metal is sufficiently cheap to encourage replacement buying, and this the market seems to expect will make itself felt before long. Some buying which is attributed to purchases by investors who were content to wait some time for a return on their money is said to have taken place, but not on an important scale. The world's production of lead in August is estimated at 98,517 tons, and for the eight months ending August 31st at 816,625 tons. . . . The market for spelter seems to have entered upon an uninteresting phase. The demand is being maintained at a steady rate, but there is plenty of metal to meet all requirements, and prices have shown little change over the week. In one respect the market seems to be working back to the position which ruled some weeks ago when the demand in this country was much more active than on the Continent. The galvanisers here who bought fairly well a few weeks ago have shown little interest in the market lately. Remelted spelter is still in short supply and the price is stiffening. Statistically, the position seems to be gradually improving. American figures give the world's output of spelter for August as 99,895 tons and for the eight months as 686,906 tons.

The Fall in Steel Imports.

The striking effect of the tariff duties is reflected in the returns of iron and steel imports into the Tees presented at last week's meeting of the Tees Conservancy Commissioners. The figures showed that only 14,331 tons were unloaded in the river during the past eleven months, as compared with 119,067 tons in the corresponding period a year ago, and 24,563 tons in 1913–14. There was an increase in the importations during September compared with August, the respective figures being 2377 tons and 989 tons. This was chiefly due to the arrival of 1550 tons of sheet bars and billets, apparently some of the cheap material which was offered by Belgian manufacturers during August.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

Public Works.

THE programme of national public works was first prepared with a view to utilising material supplied by Germany on account of reparations, and was modified in 1929 when reparations practically ceased and it was found necessary to make provision for work against the prospect of unemployment. Since then little has been done except to carry through works already in hand. Now the programme is being remodelled to be included in the general plan of financial and economic adjustment which the Government will submit at the reassembling of the Chamber of Deputies. It is understood that a sum of 20,000 million francs will be spent upon these works during the next five years. The money will be raised by a public loan, and the works must, therefore, be of a productive character, in the sense that they will be of direct benefit to the nation. Many of the undertakings included in the former plan are retained, notably the construction of motor roads similar to those being built in Germany and Italy, such roads radiating from Paris to Marseilles, Toulouse, Bordeaux, Le Havre, Lille, and Strasbourg. The rural electrification scheme will be completed, and the construction of fast ships for service between France and North Africa may be included in the list of works to be put in hand. Port authorities insist that preference should be given to harbour improvement works that were held up when no more reparation material was forthcoming. The powerful committee, backed up by the metallurgical industries, which is making strenuous efforts to induce Parliament to authorise the building of the Trans-Saharan railway, hopes that this enterprise will form part of the public works scheme. It is pointed out that while the railway may not be immediately productive, it is indispensable for the development of the African colonies and will largely pay for itself in the long run. There is, however, still hesitation in some quarters against accepting the railway as financially feasible. The suppression of level crossings and the carrying out of municipal and other schemes constitute a very long list from which the Government is making a selection. Whilst most of the proposed works will be of no immediate interest to the engineering and metallurgical industries, the extensive road-making scheme should necessitate the use of a considerable amount of machinery, although it is argued that works intended to provide employment should dispense with machinery as much as possible. The plan appeals to the public and to industrial interests as a possible means of stimulating general activity, but the expenditure on these works will constitute a mortgage on the country's future resources, unless it is assured of a sufficient return to cover the interest to be paid on the public loan. The financial attitude towards the scheme is one of extreme reserve.

Alcohol Motor Fuels.

The Government has issued a decree requiring that the alcohol-petrol fuel employed by commercial vehicle users shall be coloured by the addition of a chemical substance so that a mixture containing too high a percentage of alcohol shall not be foisted on private car owners. The heavy car fuel, with a content up to 25·9 per cent. alcohol, will be coloured rose by transparence with a yellow fluorescence. This is a result of the check which the authorities have sustained in their efforts to impose the use of a petrol-alcohol mixture in all motor cars. When the Government organised its historic Alcohol Circuit through the beet-growing districts in the north in the early days of the automobile industry, with a view to demonstrating the possibility of running vehicles on that spirit, it had in view the importance of being able to depend upon a home supply of liquid hydro-carbons in case of national emergency, and also of providing the agricultural industry with an unlimited outlet for the alcohol production which is a main factor of its prosperity. This idea of increasing the consumption of industrial alcohol was kept constantly in mind, and the matter was carefully investigated without any real advance being made until the State took over the purchase and sale of the spirit as a monopoly, when a huge accumulation of stocks showed the necessity of utilising them at almost any cost. All its attempts, however, to make the use of an alcohol-petrol mixture compulsory failed. The mixture was unstable; engines could not be started in cold weather, and pitting of valves, cylinders, and other engine parts was produced. An Office National de Combustibles Liquides was formed to investigate these and other liquid fuel problems. The results obtained were believed to be so completely satisfactory that a decree was issued two years ago requiring all petrol suppliers to add a percentage of alcohol to the mineral spirit, but the complaints of motorists led to a temporary withdrawl of the decree, although, when put into force again at the beginning of last summer, the same difficulties were experienced, so that the decree appears to have again failed in its object. So far as private cars are concerned, it is difficult to see how the alcohol mixture can come into general use when modern tendencies of automobile engine design are opposed to the conditions governing the combustion of alcohol. Motor car firms cannot design and build engines to run on a "national fuel" when they look to foreign markets for the sale of cars. It is true that the Office National affirms that a mixture of 20 per cent. alcohol with petrol will give better results than petrol alone with certain engine adjustments, but this has not been the experience of motorists who have tried the fuel and found it wanting. In the case of commercial vehicles a solution of the problem is found in the relative facility with which the heavier long-stroke engines usually fitted to them can be adapted to use the petrol-alcohol mixture. There has always been a distinction between fuels for private cars and commercial vehicles, the latter being supplied with a heavier and cheaper grade of petrol which influenced the design of engines and rendered it easier for users to adapt them to run on the new mixture. Even if the Office National des Combustibles Liquides should succeed in its efforts to eliminate the troubles complained of, there is still the question of cost. The State must supply the alcohol at cost, and even less, which explains why the State can alone achieve any success with the use of that spirit as a motor fuel.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office, Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

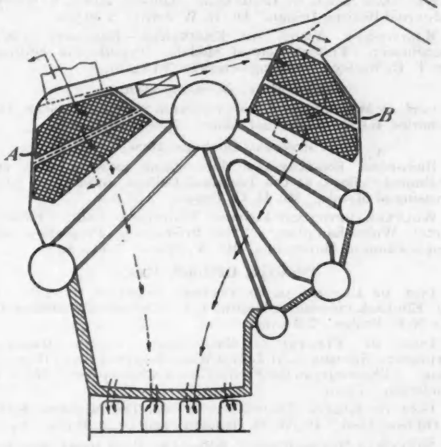
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

STEAM GENERATORS.

397,653. July 15th, 1932.—AIR PREHEATERS FOR WATER-TUBE BOILERS, H. E. Yarrow, Scotstoun, Glasgow.

It is claimed that this arrangement of an air preheater lowers the centre of gravity of the boiler. The heater is made in two sections A and B on opposite sides of the uptakes. The principal claim reads as follows:—In water-tube boilers having means for pre-heating the air for combustion in the furnaces of such boilers comprising substantially horizontal tubes on one or both sides of the boiler traversed internally by the air to be heated and externally by the furnace gases on their way to the uptake, the arrangement wherein the air pre-heating tubes on either side of the boiler are in two or more groups which are traversed in succession by the air to be pre-heated.—*August 31st*, 1933.

Nº397,653

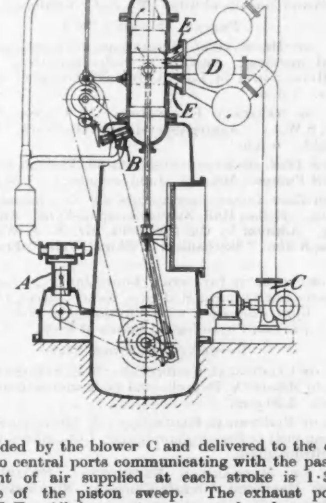


INTERNAL COMBUSTION ENGINES.

397,742. December 19th, 1932.—LARGE TWO-STROKE GAS ENGINES, *W. W. Triggs, 57, Lincoln's Inn-fields, London, W.C.2.*

The inventors do not claim originality for the individual parts of this engine, but say by their proper combination a high-speed two-stroke gas engine can be contrived in large units. The gas is supplied by the compressor A and admitted to the cylinder by the cam-operated valves B B. The scavenging air is provided by the blower C and delivered to the cylinder through two central ports communicating with the passage D. The amount of air supplied at each stroke is 1·3 times the volume of the piston sweep. The exhaust ports are shown at E E. All four ports are covered and uncovered by the piston in pairs, two for the top of the cylinder and two for the bottom. It is emphasised that the admission of gas must start as soon as possible after the exhaust port is closed so that there will be ample opportunity for the gas and air to mix.—*August 31st*, 1933.

Nº397,742

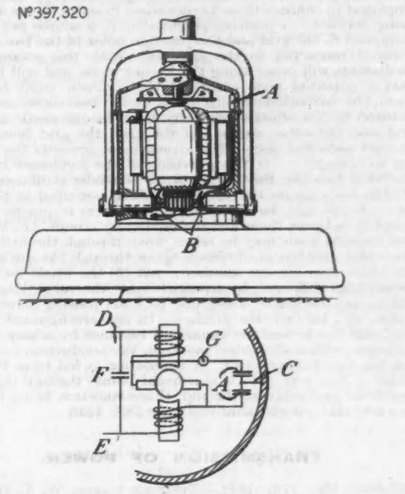


DYNAMOS AND MOTORS.

397,320. October 12th, 1932.—RADIO INTERFERENCE PREVENTIVE DEVICES, *Electrolux Ltd., of* 153–155, *Regent-street, London, W.*1.

The object of this invention is to provide an arrangement which prevents interference with radio installations operating on either short or long wave lengths, and is particularly applicable to series-wound motors driving domestic appliances. Two condensers A are arranged in the upper part of the casing and are directly connected across the brush holders B. A conductor C connects a point between the condensers A to the casing of the machine, which may be earthed. Inserted between the conductors D and E and outside the exciting coils of the motor is a third condenser F, which may be of large capacity. In the first condenser circuit, which includes the carbon brushes and condensers A, one or more fuses G may be arranged for the purpose of protecting the motor. Any interference caused by the sparking of the carbon brushes during running of the motor is, as far as short wave lengths are concerned, eliminated by the condensers A, while long wave interference is eliminated by the condenser F.—*August 24th*, 1933.

Nº397,320

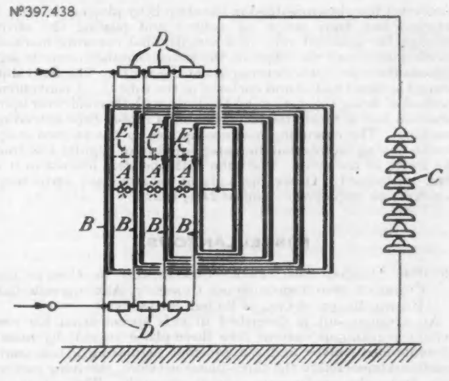


ELECTRICAL APPLIANCES.

397,438. May 3rd, 1933.—MEANS FOR PRODUCING ELECTRIC PEAK VOLTAGES, *International General Electric Company, Incorporated, of* 120, *Broadway, New York, U.S.A.*

Arrangements are known for the production of electric peak voltages, wherein a considerably increased peak voltage is produced from a direct current or an alternating current voltage source by first charging condensers in parallel through ohmic resistances and then connecting them in series. It has been found that the additional stray capacities of the separate condenser elements with respect to earth have an unfavourable influence on the multiplication of the voltage, and the object of the invention is to overcome this defect. A indicates the spark gaps and B the condensers which, in combination with the spark gaps, produce the peak voltage. C is a string of insulators under test. D are high ohmic resistances, which are so graded that they have no influence on the peak process, but which allow the condensers to be charged in the given time. The connection of the current generating plant is effected at the points indicated by the arrows. The separate condenser elements E are constructed as cylindrical condensers and are arranged concentrically one with the other. The innermost condenser forms the highest potential stage and the outermost is connected to earth. The disturbing stray capacities of the separate condenser elements with respect to earth are thereby almost completely removed, so that the voltage loss which would otherwise be caused thereby is very greatly diminished.—*August 24th*, 1933.

Nº397,438

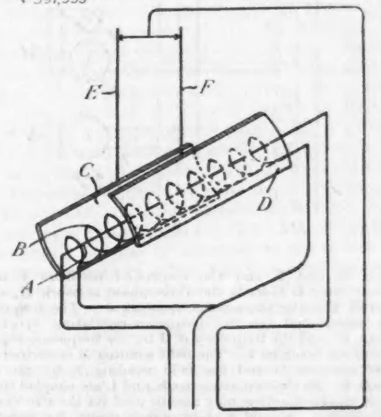


TELEGRAPHS AND TELEPHONES.

397,555. February 27th, 1932.—SHORT-WAVE OSCILLATION GENERATORS, Marconi's Wireless Telegraph Company, Ltd., of Marconi House, Strand, London, W.C.2, and Ernest Walter Brudenell Gill, of Merton College, Oxford.

The object of this invention is to provide an improved arrangement of short-wave oscillation generator, operated on the Barkhausen-Kurz principle, and wherein the action of the grid current tending to oppose oscillation is avoided. A thermionic valve, having a central straight cathode A, a cylindrical grid B surrounding the cathode, and a pair of part-cylindrical

Nº397,555



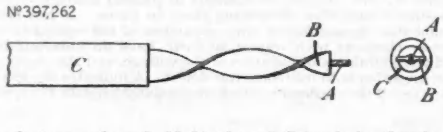
anodes C D are employed. It is found that to obtain satisfactory results with this construction of valve, the anode diameter should be not less than 2½ times the grid diameter. The two anode electrodes are connected together through a pair of Lecher wires E F in series, the large condenser ordinarily employed to connect these Lecher wires in series to one another being omitted. A positive potential from a source not shown is applied to the grid and the junction point of the two Lecher wires is connected to the cathode. With this arrangement oscillations will occur along the Lecher wires, and will be such that a potential node occurs at the junction point between them, the oscillations taking place in the two condensers constituted by the effective capacity between one anode and the grid and the other anode and the grid, the grid being thus another potential node. The arrangement presents the following advantages:—(1) The provision of the condenser hitherto provided between the Lecher wires is rendered unnecessary; (2) the leads inside the valve for taking potential to the grid and cathode may be so arranged that there is practically no coupling between them and the oscillatory circuit, *i.e.*, the grid and cathode leads may be taken down through the footstep of the valve and the anode leads taken through the envelope of the valve opposite one another; and (3) the whole oscillatory circuit can, if desired, be arranged inside the valve, thus eliminating any resistance losses due to leads passing through the valve, *e.g.*, through the pinches. In one arrangement of this kind the two anodes are connected together by a loop of wire arranged within the valve envelope, the conductors constituting the two Lecher wires. A connection is led from the mid point of this wire (which is a nodal point) through the valve envelope, preferably at the top, this connection being brought down to the cathode point.—*August 28th*, 1933.

TRANSMISSION OF POWER.

397,262. May 17th, 1932.—Electric Cable, W. T. Henley's Telegraph Works Company, Ltd., of 11, Holborn-viaduct, E.C.1; and John Henry Savage, of 13, Danson-mead, Welling, Kent.

This invention relates to the construction of cables which have a low electrostatic capacity. It has been recognised that a cable in which the wires are spaced well away from outside bodies and in which a considerable portion of the intervening space is filled with air will have a low capacity. According to the invention, a conductor A is embedded in a strip B of rubber of considerably greater width than the diameter of the wire and the strip is twisted about its longitudinal axis into the form shown. The twisted strip is enclosed in a rubber tube C. The conductor may be embedded in the strip B by placing the wire A between two thin strips of rubber and passing the strips through the grooved rolls of a longitudinal covering machine which compresses the edges of the strips together securely and embeds the wire in the centre part of the width. The strip thus formed is then twisted and enclosed in the tube C. A convenient method of doing this is to wind the strip with its conductor upon a bobbin and to rotate the latter behind a rubber tube extruding machine. The extruding machine applies to the twisted strip, a tube having an internal diameter equal to or slightly less than the width of the strip. The tube with the strip located in it is then vulcanised. Other methods of twisting the strip may, however, be employed.—*August 24th*, 1933.

Nº397,262

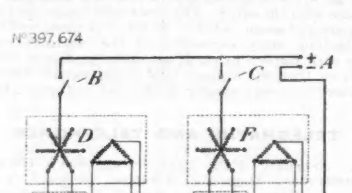


MISCELLANEOUS.

397,674. August 29th, 1932.—Conversion of Continuous Current into Three-phase Current, Aktiengesellschaft Brown, Boveri et Cie., of Baden, Switzerland.

An arrangement is described in this specification for converting continuous current into three-phase current by means of controlled valves and a frequency regulating synchronous machine connected to the three-phase network, receiving current only from the continuous current network. The scheme is characterised by the feature that the three-phase network is divided into two parts, which receive their energy from separate converter groups, and that the frequency-regulating machines of both networks are mechanically coupled. In the drawing A is the continuous-current network: B and C the main continuous current switches of the two continuous current to three-phase current converters G, formed by the transformers D and F and the controlled rectifiers E and G. The converter D E feeds the three-phase network H, and the converter F G the three-phase network J. The frequency of H is determined by the frequency-regulating synchronous machine K, and the frequency of J by the frequency-regulating synchronous machine L. The field winding M is excited by the exciter machine O and the field winding N by the exciter machine P. As the two machines K and L are coupled together, a single exciter machine may also be used for the two synchronous machines. Should a short-circuit occur, for instance, in the network H, the machine K will, after the switch B has opened automatically, work as a generator on to the network H. The machine K will then be driven by L, which will prevent the speed of K appreciably dropping. When the faulty part of the network H has been disconnected, the switch B can be closed again without a dangerous current surge.—*August 31st*, 1933.

N° 397,674



Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the TIME ***and*** PLACE ***at which the meeting is to be held should be clearly stated.***

To-day.

Inst. of Electrical Engineers: N.E. Students' Section.—Armstrong College, Newcastle-upon-Tyne. Chairman's address, "The Rating and Performance of Circuit Breakers," Mr. R. W. L. Harris. 7.15 p.m.

Inst. of Engineers and Shipbuilders in Scotland.—Grosvenor Restaurant, Glasgow. "James Watt" dinner.

Inst. of Metals: Sheffield Local Section.—In the Non-ferrous Section of the Applied Science Department of the University, St. George's-square, Sheffield. "Centrifugal Casting of Non-ferrous Alloys," Mr. F. W. Rowe, B.Sc. 7.30 p.m.

Junior Inst. of Engineers.—At 39, Victoria-street, S.W.1. "The Influence of Harmonics in Transformer Circuits," Mr. Ernest Ambrose, M.I.E.E. 7.30 p.m.

Keighley Assoc. of Engineers.—Queen's Hotel, Keighley. "Journal Bearing Design," Dr. H. W. Swift. 7.30 p.m.

Manchester Assoc. of Engineers.—Engineers' Club, Manchester. Presentation of Medals. Presidential address, Dr. T. B. Morley. Smoking concert. 7.15 p.m.

Saturday, October 14th.

Inst. of Marine Engineers: Junior Section.—85–88, The Minories, E.C.3. Social and dance. 7.30 to 11.15 p.m.

Monday, October 16th.

Bradford Engineering Soc.—Joint meeting with the Technical College, at the Technical College, Bradford. "Degreasing of Metals," Mr. H. O. Brown. 7.30 p.m.

Wolverhampton and District Engineering Soc.—Victoria Hotel, Wolverhampton. "The Production, Properties, and Applications of Aluminium," Mr. W. Tyson. 7.30 p.m.

Tuesday, October 17th.

Inst. of Electrical Engineers: Scottish Centre.—At 39, Elmbank-crescent, Glasgow, C.2. Chairman's address by Mr. N. C. Bridge. 7.30 p.m.

Inst. of Electrical Engineers: South Midland Students' Section.—At James Watt Memorial Inst., Birmingham. "Electricity in the Production of a Newspaper," Mr. J. R. Anderson. 7 p.m.

Inst. of Marine Engineers.—85–88, The Minories, E.C.3. "Oil from Coal," Dr. W. R. Ormandy and Dr. J. Burns. 6 p.m.

Sheffield Metallurgical Soc.—198, West-street, Sheffield. "Exhaust Valve Failures," Mr. C. C. Hodgson. 7.30 p.m.

Wednesday, October 18th.

Inst. of Electrical Engineers: South Midland Centre.—Grand Hotel, Birmingham. First general meeting. Chairman's address, Mr. J. Coxon. 6.50 p.m.

Inst. of Fuel.—In the Lecture Hall of the Geological Soc. of London, Burlington House, Piccadilly, W.1. Presidential address by Sir Wm. J. Larke. 11.30 a.m. "Recent Developments in Coking Practice," Dr.-Ing. H. Koppers. 2.30 p.m. Connaught Rooms, Great Queen-street, W.C.2. Annual dinner and dance. Presentation of the Melchett Medal to Sir John Cadman. 6.45 for 7.15 p.m.

Inst. of Locomotive Engineers (London).—Dudley Room, Queen's Hotel, Birmingham. Presidential address, "Colonial Railways," Major Charles E. Williams. 7 p.m.

Inst. of Production Engineers: Birmingham Section.—At James Watt Memorial Inst., Gt. Charles-street, Birmingham. Discussion, "Unusual Production Processes," Opener, Mr. G. H. Wray. 7 p.m.

Royal Microscopical Soc.—B.M.A. House, Tavistock-square, W.C.1. Meeting at 5 p.m.

Thursday, October 19th.

Inst. of Production Engineers: Glasgow Section.—At 39, Elmbank-crescent, Glasgow. "Survey of Latest Engineering Materials and Machineability," Mr. A. C. Macdonald. 7.30 p.m.

Friday, October 20th.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. Informal meeting; election of Sub-committee. Discussion, "The Horse-power of Locomotives," introduced by Mr. A. G. Hopkins. 7 p.m.

Inst. of Sanitary Engineers.—At Caxton Hall, Westminster, S.W.1. "Aggregates for Concrete Work," Dr. Bernard H. Knight. 6 p.m.

Junior Inst. of Engineers.—At 39, Victoria-street, S.W.1. "Air Lift Pumps," Mr. A. C. Judd (member). 7.30 p.m.

North-East Coast Institution of Engineers and Shipbuilders.—Bolbec Hall, Newcastle-upon-Tyne. Annual general meeting. Address by the President, Mr. R. J. Walker; cinematograph film, "Mechanism of Ships' Wake," Professor T. B. Abell.

Soc. of Chemical Industry (Food Group).—London School of Hygiene and Tropical Medicine, Keppel-street, Gower-street, W.C.1. Joint discussion with Physiological Soc., "Diet from the Chemical and Physiological Points of View." 8 p.m.

Saturday, October 21st.

Inst. of Electrical Engineers: N.E. Students' Section.—Visit to Messrs. A. Reyrolle and Co.'s short-circuit test plant, Hebburn. 2.30 p.m.

Inst. of Electrical Engineers: S. Midland Students.—Afternoon visit to *Birmingham Gazette*, Ltd., offices, Corporation-street, Birmingham.

Inst. of Mechanical Engineers: Graduates.—Visit to the de Havilland Aircraft Company, Stag-lane Aerodrome, Edgware.

Tuesday, October 24th.

Inst. of Automobile Engineers.—At Hotel Victoria, Wolverhampton. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7.30 p.m.

Inst. of Engineers and Shipbuilders in Scotland.—39, Elmbank-crescent, Glasgow, C.2. "Flame Cutting of Steel for Welded Joints," Mr. E. J. Clarke. 7.30 p.m.

Sheffield Metallurgical Soc.—198, West-street, Sheffield. "Our Knowledge of the Conditions in the Blast-furnace," Mr. R. C. Tucker. 7.30 p.m.

Wednesday, October 25th.

Inst. of Mechanical Engineers: Yorkshire.—Grand Hotel, Sheffield. "Fatigue and Corrosion Fatigue, with Special Reference to Service Breakages," Prof. Frederic Bacon. 7.30 p.m.

Thursday, October 26th.

Glasgow University Engineering Soc.—At James Watt Engineering Laboratories, University. Presidential address by Mr. H. A. Reincke. 7.30 p.m.

Inst. of Electrical Engineers.—Savoy-place, W.C.2. Presidential address, Mr. P. V. Hunter. 6 p.m.

Inst. of Mechanical Engineers.—At Dorchester Hotel, Park-lane, W.1. Annual dinner, 6.45 for 7.15 p.m.

Inst. of Mechanical Engineers: Yorkshire.—Queen's Hotel, Leeds. "Fatigue and Corrosion Fatigue, with Special Reference to Service Breakages," Prof. Frederic Bacon. 7.30 p.m.

Midland Metallurgical Societies.—In the James Watt Memorial Inst., Gt. Charles-street, Birmingham. Discussion, "The Production of Sound Cast Iron Castings." 7 p.m.

Friday, October 27th.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. General meeting. Presidential address, Mr. Alan E. L. Chorlton. 6 p.m.

Junior Inst. of Engineers.—At 39, Victoria-street, S.W.1. "The Electrolytic Theory of Corrosion," Mr. H. E. Yerbury, M. Inst. C.E., M.I. Mech. E., M.I.E.E. 7.30 p.m.

Saturday, October 28th.

Stephenson Locomotive Society.—Visit to Stratford, L.N.E. Railway Running Sheds. 2.30 p.m.

Monday, October 30th.

Bradford Engineering Soc.—Technical College, Bradford. "Salvage Work on the Ex-German Fleet at Scapa Flow," Mr. E. F. Cox. 7.30 p.m.

Inst. of Automobile Engineers.—At 39, Elmbank-crescent, Glasgow. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7.30 p.m.

Inst. of Mechanical Engineers: Graduates.—Storey's-gate, S.W.1. "Stainless Steels in Aeroplane Structures," Mr. F. J. Murdoch. 6.45 p.m.

Tuesday, October 31st.

Inst. of Transport.—15, Savoy-street, W.C.2. Discussion, "The Duties of a Modern Transport Manager," Mr. M. F. Barnard.

Thursday, November 2nd.

Inst. of Automobile Engineers.—Queen's Hotel, Birmingham. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 8 p.m.

Friday, November 3rd.

Inst. of Marine Engineers.—Grosvenor House, Park-lane, W.1. Annual conversazione. 7 p.m.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. Thomas Hawksley Lecture, "Kinematic Design in Engineering," Professor A. F. C. Pollard. 6 p.m.

Railway Club.—57, Fetter-lane, E.C.4. "Train Ferries: Their History and Development," Mr. S. R. Yates. 7.30 p.m.

Friday, November 10th.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. Informal meeting. Discussion, "Financing Industry," introduced by Mr. Sydney Parkes. 7 p.m.

Monday, November 13th, to Saturday, November 18th.

Public Works Congress and Exhibition.—Agricultural Hall, Islington, N.1. Daily.

Thursday, November 16th.

British Waterworks Assoc.—Agricultural Hall, Islington, N.1. To receive and discuss the following papers:—"Pooling of Supplies by Interconnection of Water Undertakings and their Trunk Mains through Rural Areas," Mr. Alan E. L. Chorlton; "Water Pollution Research," Dr. A. Parker. 11 a.m. Afternoon session: "The Financial Management of Municipal Trading Departments," Mr. Sydney Larkin; "Water Supply and Fire Protection," Mr. John Smith; "Fire Prevention and Fire Extinguishing Apparatus," Major F. W. Jackson; "The Legal Aspect of Water Supply for Fire Protection Purposes," Mr. John Hall. 2.45 p.m.

Tuesday, November 28th.

Inst. of Electrical Engineers: Scottish Centre.—Grosvenor Restaurant, Gordon-street, Glasgow, C.2. Annual dinner and ladies' evening. 6.30 p.m. for 7 p.m.

LAUNCHES AND TRIAL TRIPS.

Port Chalmers, twin-screw motorship; built by Swan, Hunter and Wigham Richardson, Ltd., to the order of Commonwealth and Dominion Line, Ltd., of London; dimensions, 486½ft. by 65¼ft.; to carry cargo. Oil engines, of Barclay-Curle Doxford Diesel type; constructed by Barclay, Curle and Co., Ltd.; launch, October 3rd.

Baron Elgin, steel screw steamer; built by D. and W. Henderson and Co., Ltd., to the order of Messrs. H. Hogarth and Sons, Glasgow; dimensions, 365ft. by 51ft. 6in. by 26ft.; to carry cargo. Engines, triple-expansion, pressure 210 lb. per square inch; constructed by the builders; trial trip, October 4th.

Sir Russell, single-screw, self-trimming collier; built by Swan, Hunter and Wigham Richardson, Ltd., to the order of Stephenson Clarke and Associated Companies, Ltd., London; dimensions, 252ft. by 36½ft. by 18ft.; to carry coal. Engines, triple-expansion, 19in., 31in., 51in. diameter by 36in. stroke, pressure 180 lb. per square inch; constructed by the builders; launch, October 4th.

Prabhavati, twin-screw steamer; built by Harland and Wolff, Ltd., to the order of the Bombay Steam Navigation Company; dimensions, 199ft. by 34ft. by 11ft. 6in.; to carry cargo and passengers. Engines, triple-expansion; constructed by the builders; trial trip, recent.

Water Softeners at St. Helens.—After the "Permutit" water softeners at the St. Helens new water purification plant at Sutton-road, opened on September 28th, have passed 25,000 gallons of water per hour for several hours, the Base-Exchange bed becomes exhausted and requires complete revivification, which operation is called regenerating. The process of regeneration is effected by passing through the softeners a solution of common salt or sodium chloride. The effect of this solution on the bed of Base-Exchange material is to remove the calcium and magnesium salts, which leave the plant in the form of calcium and magnesium chloride, *i.e.*, a perfectly clear solution. The sodium of the sodium chloride replaces the sodium in the Base-Exchange material, thus leaving the bed completely revivified. St. Helens, for this particular operation, has a design which is quite unique, inasmuch as instead of the salt for each regeneration having to be weighed out carefully, taken to its salt tank, and mixed with water, the supply necessary for a week or ten days can be stored in such a way that the saturated solution is always ready by merely opening a valve. Added to this saturator there is a storage compartment containing complete storage of saturated brine ready for passing to the measuring tanks whose volume is such that it represents the exact quantity required to regenerate the units. Very careful safeguards are provided to ensure that the specific gravity in each of the brine compartments is as exactly required. Another interesting feature about this section of the plant is the fact that in order to ensure the utmost economy in brine, after the solution has been used once, it is returned to a compartment known as the "old brine compartment," and at the next regeneration is used again before being passed down the drain.

A Seven-Day Journal

◆

Car Prices and Road Accidents.

Speaking at the annual dinner of the Motor Agents' Association on Monday last, Sir Herbert Austin said that a drastic reduction in the selling costs of cars should be undertaken at once, and that the first step ought to be the cutting out of at least half of the people at present receiving agency terms. Economic conditions did not admit of a reduction in prices to-day without a decrease in the quality, and nothing in the world could do the British motor car industry greater harm than to reduce quality. He saw no likelihood of any reduction in prices at the present time, and thought it would be a great pity if any attempt was made by any firm to cut prices. Lamenting the number of deaths from road accidents, he said that he had had a long talk with the Minister of Transport, and he was very much afraid that, if means were not discovered for the reduction of the total number of such accidents, the old speed limit would return. That would prove an enormous setback to the trade. All associated with the industry, particularly agents, ought to do everything they could to get clients to appreciate the danger there was of a return to the old speed limit, and to impress upon them the necessity of careful driving.

A Powerful Ocean-going Tug.

The new motor tug "Zwarte Zee," which last week completed her official speed and power trials, and will be stationed at Brest during the winter months in the service of L. Smit and Co.'s Internationale Sleepdienst, is stated to be the most powerful ocean tug towing, and salvage, vessel afloat. She was built at the Kinderdijk yard of Smits Machinefabrieken, and was engined by the Werkspoor Company, of Amsterdam, and has a length of 59·7 m., a beam of 9·7 m., and a depth of 5·9 m., with a registered tonnage of 792 gross tons. The propelling machinery comprises two Werkspoor oil engines, with a total of 4200 H.P., which drive the single propeller through mechanical gearing, and a Vulcan hydraulic coupling. When running free, a speed of 17½ knots is attained. A specially large bunker capacity for a round-the-world trip without bunkering has been provided. The navigation equipment includes wireless telegraphy with direction-finding equipment, and other modern navigating instruments and fittings. As the tug may be called upon to act as a salvage vessel, a very complete salvage equipment has been included. It comprises not only fire-fighting apparatus, but diving gear and salvage pumps of large capacity. The new tug has a short, squat funnel, which gives her an individual appearance.

Shipbuilding Employers' Federation.

The annual general meeting of the central board of the Shipbuilding Employers' Federation took place in Edinburgh on Thursday, October 12th, when Mr. G. Tristram Edwards, the assistant managing director of Smith's Dock Company, Ltd., of North Shields, Middlesbrough and Stockton, was elected President for the ensuing year in succession to Mr. J. B. Hutchison, of Scott's Shipbuilding and Engineering Company, Ltd., of Greenock. The re-elected Vice-presidents are Mr. C. S. Swan, of Swan, Hunter and Wigham Richardson, Ltd., and Mr. Maurice E. Denny, of William Denny and Brothers, Ltd., of Dumbarton. Mr. F. E. Rebbeck, the chairman of Harland and Wolff, Ltd., Belfast, was also elected a Vice-president to fill the vacancy caused by the election of Mr. Tristram Edwards as President. Mr. H. Main, of the Caledon Shipbuilding and Engineering Company, Ltd., of Dundee, was appointed chairman of the Conference and Works Board of the Federation, with Mr. F. C. Mullens, of the Port Talbot Shipbuilding and Graving Dock Company, Ltd., Port Talbot, as vice-chairman. On Friday of last week, the Federation met representatives of the shipyard trade unions and discussed the proposals to create a separate class of electric welders for shipyard work. Both sides considered the matter carefully, but it was declared impossible by the shipyard unions' representatives that the unions would agree with the employers' proposals, and the whole matter was finally referred to the arbitration of the independent chairman, Mr. T. Graham Robertson, K.C., who, it may be recalled, succeeded Lord Macmillan in that capacity some three years ago.

Beauty in Machinery.

On Friday, October 13th, Dr. T. B. Morley delivered his inaugural address as President of the Manchester Association of Engineers. In it he dealt with what engineers might do to decrease the nuisances they have created and to augment the amenities of life. We quote from it the following interesting passage :—"No true engineer and no true craftsman is content to despise mere appearances. Our predecessors tried to beautify their work by the addition of ornamentation. One finds old beam engines with fluted cast iron columns with capitals in imitation of carved stonework. I am thankful that taste to-day abhors such inappropriate and functionless adornment and follows the simpler standards of good proportion and adaptation to purpose. Admittedly, that quality in a machine or engine that can have any claim to the term beauty takes a trained mind for its discernment. Undoubtedly, however, there is something not unworthy of that name in a structure or mechanism in which the parts are well proportioned and well finished, and in which the whole is in harmony and reveals the underlying principle of fitness to purpose. The designer and the draughtsman may justly take pride in fitness and cleanness and harmony of design, though it is as impossible to define what those terms mean as it is to describe a sunset to a man born blind. Perhaps the best illustration of their meaning is afforded by the want of harmonious design shown by certain locomotives, which look as if the designer had simply stuck accessories round the primary design in a way that suggests they were all afterthoughts and he had not taken the trouble to remodel the primary design to accommodate them in a pleasing manner. But design is not all. Let the man in the shops take pride—and may he have the chance to do so—in sound workmanship and neat finish. Minor details can make or mar appearance. Oil pipes that are wavy and laid at all sorts of angles will carry oil to lubricating points quite effectively, but what a difference it makes to the look of an engine when the oil pipes are run neatly in straights and evenly curved bends, in lines that conform to the lines of the engine."

A Steel Firm's Jubilee.

The firm of H. J. Skelton and Co., Ltd., iron and steel merchants, Royal London House, Finsbury-square, London, E.C.2, celebrates its fiftieth anniversary this month, having been founded in 1883. Even in those distant days the founder, Mr. H. J. Skelton, had achieved a position in the British iron and steel trades, although he had previously been connected with the works side of the business. Under his guidance the firm became known as one of the most enterprising merchant houses in the steel trade. Amongst the contracts it handled was the supply of the steel for the hull of the Dreadnought "Thunderer," the last battleship to be built on the Thames. It also provided the steel for the Boulac and Embabeh bridges in Egypt, which were erected by French and Belgian builders, but constructed of British steel. This was largely due to the initiative of the firm in giving the builders an all-round price in their own currency delivered at their works, and in covering them for a period. Another outstanding transaction was the purchase from the Government Disposal Board of the whole of the British Admiralty stock of steel for fabricated ships, amounting to 66,000 tons, at a price of over £1,000,000. On another occasion the Crown Agents for the Colonies permitted the firm to supply rails for the Gold Coast Railways without inspection, thus putting upon a merchant firm the onus of supplying materials of suitable quality. Mr. H. J. Skelton has retired from the business for the past few years, but his work in connection with the British Engineering Standards Association—now the British Standards Institution— and in many other directions will stand as a reminder of a forceful and likeable personality.

British Exports.

The oversea trade returns published last Friday make cheerful reading, as they fully confirm the general impression that industry is rising from the deepest trough of the depression. Compared with the corresponding month—September—last year, the value of British exports rose by the substantial figure of nearly £6,000,000, the total for this year being £32,226,287. Treated from the engineer's standpoint, it is gratifying to find that out of the total increase no less than £4,981,000 was due to manufactured goods in general. No single group of manufactured goods showed a decline, while such important industries as the iron and steel, non-ferrous metal, machinery and textiles, all showed substantial improvement. This country, comparatively, exports but few raw materials. But coal, which is by far the most important of our exports falling under this category, accounts for nearly one-half of an increase of £875,000. That the expansion in the export trade is still continuing appears to be indicated by the increase of £1,230,000 in exports in September over those of the preceding month. This expansion, too, was spread over a large number of groups.

Tramp Shipping.

The Chamber of Shipping announced at the end of last week the *personnel* of the special committee which it has invited to serve under the chairmanship of Mr. R. J. Dunlop, of Glasgow, to investigate fully the present position of British tramp shipping. The committee is a strong one and is fully representative of different shades of opinion. Its work will be to examine fully all questions bearing on the present plight of the industry, including the subsidising of foreign shipping. It will also consider possible remedial measures, such as the laying up of ships and scrapping programmes to be carried out either with, or without, Government support. It may be recalled that the Chamber of Shipping freight index number for last month was only 70·73, compared with 100 as the average of the general index numbers for 1913. The present figure is the lowest recorded since 1920, when the recording of index numbers was first begun by the Chamber. It is expected that the committee which has been appointed will meet as soon as the material prepared for its consideration is ready. In due course it will report to the Council of the Chamber of Shipping, of which Mr. W. T. McAlister, the chairman and managing director of the General Steam Navigation Company, Ltd., is the President.

The Galloway Power Scheme.

By the clearing of the final barrier in the Glenlee Tunnel on Tuesday, October 10th, another stage in the harnessing of the water power resources of Southern Scotland for the service of industry was reached. Lord Meston, chairman of the Galloway Water Power Company, presided at the "break through" ceremony, and Sir Andrew Duncan, Chairman of the Central Electricity Board, fired the final round of explosives. The construction of the tunnel, which is an important part of the scheme, is being carried out by Mr. A. M. Carmichael, works contractor, Edinburgh. In welcoming Sir Andrew Duncan, Lord Meston explained that the tunnel, which was 3½ miles long, would carry the water from a new reservoir to the hydro-electric station at Glenlee, and that the complete scheme would provide power for Southern Scotland and the great industrial areas of Glasgow. The work had moved towards the general well-being of Great Britain and that would be remembered when kindly Nature had covered up the scars the engineers had been forced to make on the countryside. In replying, Sir Andrew Duncan congratulated the contractor on the excellence of his work. Subsequently Mr. Carmichael explained that in the process of breaking through the rocks 200 tons of explosives and 150,000 detonators had been used without a single fatal or serious accident. The work had been hard, difficult, and dangerous, but the men engaged upon it had given of their best. He also congratulated the sub-contractors, including Nobels Explosives, the Consolidated Pneumatic Tool Company, which supplied all the rock drills, and the Sullivan Machinery Company, which was responsible for the scrapers for removing the *débris*.

The Late Hon. Lady Parsons.

It is with deep regret that we have to record the death of the Hon. Lady Parsons, which took place at her home at Kirkwhelpington, Northumberland, on Monday last, October 16th, after a long illness. Lady Parsons, who married the Hon. Sir Charles Parsons in 1883, was deeply interested in her husband's many occupations, and in particular she sponsored the work of women in the engineering industry. She was one of the founders of the Women's Engineering Society, and when, in 1920, eight girls started the engineering business of Atalanta Ltd., in South London, she assisted the new enterprise and took a keen interest in the firm. She is survived by her daughter, Miss Rachel Parsons, who passed through the Cambridge University engineering school, and during the war served in the training department of the Ministry of Munitions.

An Oil-Electric Tug for Thames Service.

Throughout the present week daily demonstration trials have been carried out on the Thames, with the new oil-electric tug "Lectro," which has been specially constructed for the Shell-Mex B.P. oil barge towage service of the Union Lighterage Company, Ltd., of London. In the building of the tug Henry Robb, Ltd., of Leith, shipbuilders, Mirrlees Bickerton and Day, Ltd., of Hazel-grove, Stockport, and the British Thomson-Houston Company, Ltd., of Rugby, co-operated. An outstanding feature of the design is the direct control of the engines and the propulsion motor from the bridge. We attended the trials carried out on the Barking Reach on Tuesday, October 17th, and witnessed for ourselves the remarkable manœuvring capabilities of the tug. She has an overall length of 92ft., a beam of 22ft., a depth of 11ft. 6in., and a forward draught of 7ft. 6in., with an after draught of 11ft. 9in. There are two six-cylinder, 360 B.H.P. Mirrlees airless injection engines, which are direct-coupled to 250-volt D.C. compound-wound B.T.H. main and auxiliary generators running at 300 r.p.m. The generator output is designed to meet the full power requirements of a 580 S.H.P. motor operating at 500 volts with a speed range of 120 to 150 r.p.m. The two 20 kW auxiliary generator sets furnish power for excitation and ship's auxiliaries. The bridge control includes two stations of the standard bridge telegraph type, which are mechanically connected one with the other and operate the electrical control gear, which governs the running of the engines. We operated for ourselves the controls and found them easy, with a quick response of the machinery. The tug will be shortly commissioned, when it is expected that a full record of her performance will be available for publication.

The Hoover Dam on the Colorado River.

No. I.

The great Hoover Dam* project has gone steadily forward since we dealt with the subject in our issues of December 9th and 16th, 1932. Notwithstanding the unprecedented magnitude of the undertaking, work in certain particulars is several months ahead of the schedule which was agreed upon when the general contract was awarded to Six Companies, Incorporated, on March 11th, 1931. If the present pace be maintained, it is probable that water will be passing through the turbines a year sooner than was originally planned. The progress so far made is attributable to the energy and resourcefulness of the Six Companies' organisation and to the whole-hearted collaboration of the Bureau of Reclamation of the Federal Government. The Bureau of Reclamation, since it was called into being thirty-one years ago, has accumulated a vast fund of experience and technical data which has been drawn upon in developing the plans for the Hoover Dam and its associated features.

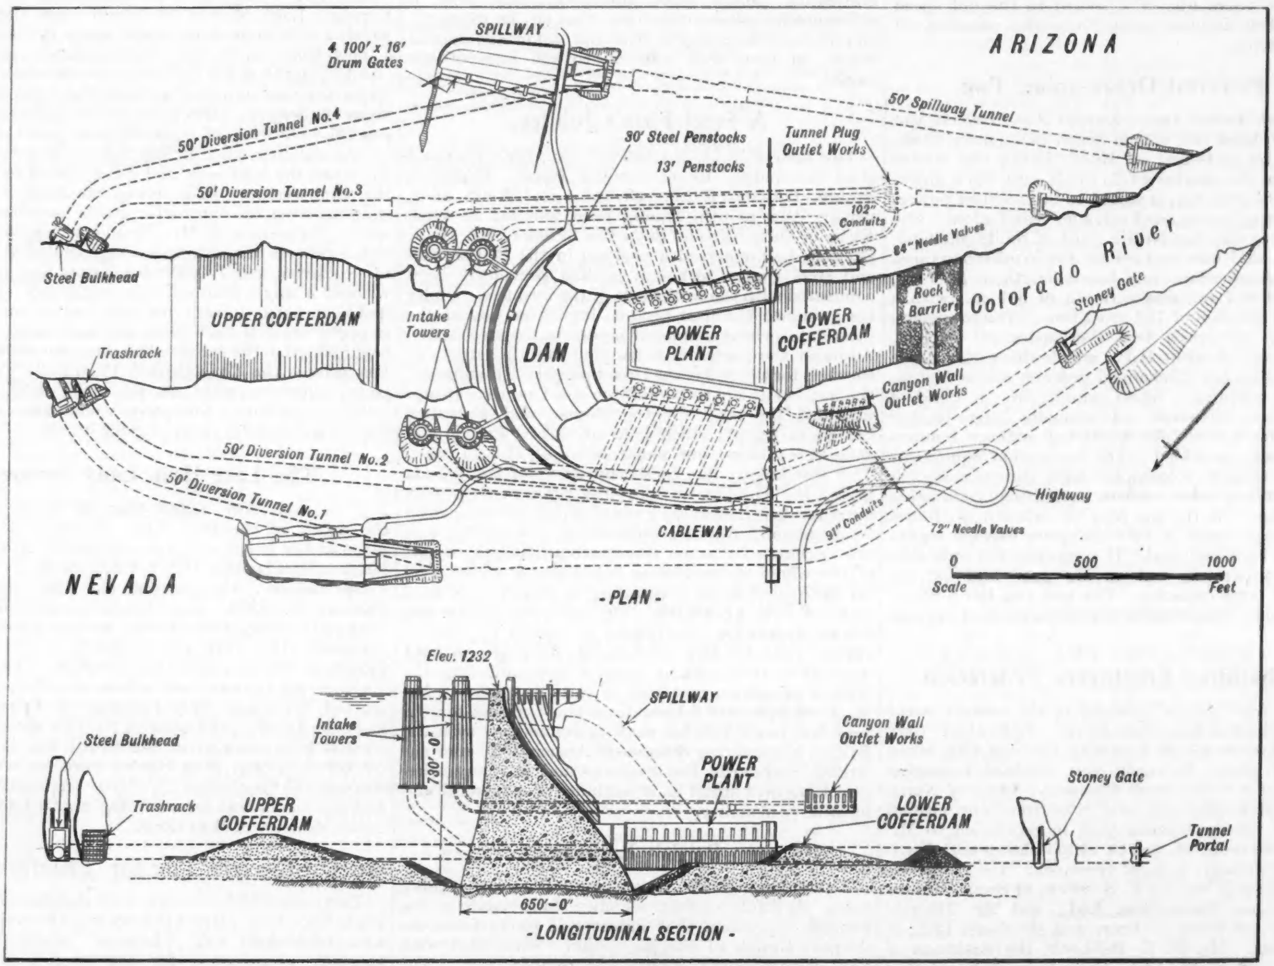


Fig. 1—General Plan and Section of the Hoover Dam as Finally Modified

We concluded our previous notice by referring to the advanced stage reached in the work of lining the four 50ft. diversion tunnels. On November 13th and 14th last Diversion Tunnels Nos. 3 and 4—see Fig. 1—were ready to receive the diverted flow of the Colorado River. On these two days large blasts of dynamite cleared away the barriers at the inlet portals of the two tunnels. The admission of water to Diversion Tunnels Nos. 3 and 4 marked the climax of the preparatory work covering a period of a year and a-half. The barriers blown away were portal cofferdams constructed to protect the diversion tunnels from inundation in the event of a high-level flood occurring before the tunnels were ready for service.

Early in the preceding September a spur dump, formed of material from the adjacent tunnel excavations, was extended out from the Nevada wall of the canyon until it reached midstream, the spur being started from a point a short distance downstream from the intake portals of Diversion Tunnels Nos. 1 and 2. This spur, made by end dumping from motor trucks, was then continued downstream, roughly parallel with the shore line for fully 700ft. and then turned at right angles back to the Nevada side of the canyon. The enclosed area, which was shortly afterwards unwatered, covered half the site for the main or upstream cofferdam that was completely to block the river and divert any probable flood through the four tunnels. Besides crowding the stream to the Arizona side of the canyon, this temporary barrier enabled part of the river bed to be cleared for the purpose of reaching a suitable foundation for the upstream cofferdam. A 5 cubic yard electric dragline and a number of 3½ cubic yard electric shovels, with a fleet of motor trucks, were set to work excavating the exposed river bed. This work was continued down to a depth of 18ft., through silt and sand, when a stratum, composed of an admixture of sand, gravel, cobbles, and boulders, was reached. This stratum was deemed amply stable for the desired foundation and was at a point 98ft. below the crest of the prescribed cofferdam—that is, at elevation 622ft.

Immediately after water was admitted to the two Arizona diversion tunnels operations were started a short distance downstream from those intakes to extend the initial spur, forming the upper end of the temporary barrier, so as completely to block the bed of the river and to send all the water through the two diversion tunnels. A timber trestle bridge extending to the Arizona side of the canyon was used as a means to this end, and from it motor trucks dumped material on both sides. Within thirty hours following the initial diversion of the river the temporary dam had been raised high enough to send the entire flow of the river into the two available tunnels. This closure having been effected, the unwatering of the remaining half of the site for the upstream cofferdam was begun. Seepage through the temporary barrier was checked by widening and heightening it with material removed from the cofferdam site. Shortly after the bed of the river was blocked in this manner a corresponding barrier was formed just upstream of the diversion tunnel discharge portals. These works concluded the preparations leading to the construction of the upper and lower cofferdams that were to make possible the subsequent excavation of the rock underlying the site of the Hoover Dam.

The Upper Cofferdam.

The upper cofferdam was considered to be so monumental and the stresses which a high flood level flow of 200,000 cubic feet per second would impose on it so great that the Government assumed responsibility for the integrity of the structure. The contractor's liability was limited to adherence to specifications prescribed by the Bureau of Reclamation. In accordance with those specifications, the main mass of the cofferdam is made up of an earth-gravel fill composed of 568,000 cubic yards, with a rock blanket of dumped riprap 3ft. thick on each slope. All told, 157,000 cubic yards of rock were used for the blanket, and silt and clay were sluiced into the voids to consolidate it. The upstream face is on a 3 : 1 gradient and the downstream slope is 4 : 1. The earth fill was compacted with 6-ton Rohl rollers, each drawn by a 30 horse-power tractor, and the earth, after being dumped from motor trucks, was spread by bulldozers attached to 30 horse-power caterpillar tractors. The earth was obtained from pits about 3 miles upstream, near the mouth of Hemenway Wash. At the pits electric shovels equipped with 3½ cubic yard dippers dug the material and loaded it into 30-yard side-dump cars that were hauled on the railway running along the Nevada side of the canyon above the high-water level. This railway was built by the contractor and required the driving of tunnels and the excavating of solid rock for a distance of fully 2 miles. When the earth from the pits reached the lower end of the railway it was dumped from a trestle and reloaded into motor trucks by 3½ cubic yard shovels and then hauled to points on the cofferdam site. During some twenty-four-hour periods as much as 18,000 cubic yards or 4000 truckloads of earth were placed in the cofferdam. As soon as the horizontal layers of earth were approximately a foot in thickness each of them was uniformly moistened and compacted by rolling. The earth contained an admixture of gravel, but no stones of a greater dimension than 9in. were permitted in this material. Thirty-five trucks were employed on this work. The shovels lifted and dumped a dipperful every thirty seconds, almost continuously day and night, operations after nightfall being made possible by an extensive arrangement of electric lamps.

The upstream toe of the cofferdam is protected by a cut-off consisting of a line of steel sheet piling driven into the river bed down to rock and extending from wall to wall of the canyon. The piles are of the arch web type and are 16in. wide, from 40ft. to 55ft. in length, and have a continuous interlock rolled in them from end to end. For the most part they were driven by means of a large McKiernan-Terry pneumatic hammer, but for a space near the Nevada wall numerous big boulders prevented driving. Throughout this stretch a trench was excavated and the piles were set on a concrete footing resting on basic rock. A 5 cubic yard drag-line fitted with an 80ft. boom was used to put the piles in their prescribed positions and then to hold the air hammer while the driving was being performed.

---

* It seems desirable to continue to refer to the dam by its original title, in spite of the fact that it has been changed by officials of the new administration, which came into power with Mr. Roosevelt, to Boulder Dam. The dam is being constructed in Black Canyon. Boulder Canyon was considered as a site for it, but was abandoned in favour of the adjacent Black Canyon.

On each flank of the cofferdam anchored in vertical channels cut 3ft. deep in the rock are three concrete cut-offs 98ft. high which reach from bed rock to the crest of the cofferdam. These cut-offs are spaced 25ft. apart centre to centre. They are 8ft. across on their outer faces and project into the fill of the dam to a depth of about 5ft. The cut-offs are designed to obstruct seepage working its way downstream between the canyon walls and the body of the cofferdam and were poured in successive lifts as the earth fill mounted. The concrete required was hauled from the mixing plant in 4 cubic yard agitators and the agitators were lifted from the trucks and swung to the pouring sites by the large drag-line.

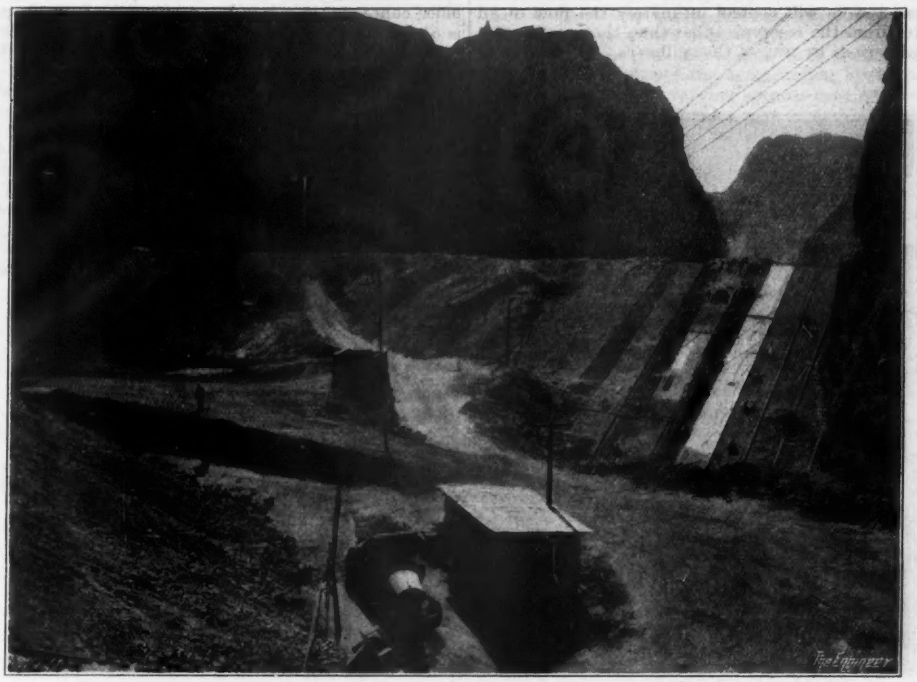

Fig. 2—Concreting the Upstream Face of the Upper Cofferdam

The rock for the 3ft. blankets on the front and rear slopes of the upstream cofferdam was obtained from the material produced in scaling the canyon walls and in excavating those walls for some of the external structural features of the project. The blankets were not placed on the slopes until the earth fill was nearly completed. While the building up of the cofferdam was still in progress, work was started on the 6in. reinforced concrete paving that covers the entire front face of the upstream cofferdam—see Fig. 2. According to the specifications: "The concrete paving shall be laid in strips not over 16ft. in width running up and down the slope of the cofferdam, and construction joints, across which the reinforcement bars shall be continuous, shall be provided between the strips." These 16ft. sections rise from a concrete curb at the sheet-piling cut-off and extend to the crest of the dam. The concrete used was trucked to the crest of the cofferdam and then delivered to the placing points through timber chutes. The pavement is composed of 3500 cubic yards of concrete and 251,000 lb. of ⅝in. reinforcing steel bars. In addition to the reinforced concrete pavement and the three concrete cut-offs in each canyon wall, seepage is further guarded against by a rubber fabric seal at each side of the canyon, and by a rubber seal at the lower edge of the pavement. The connection between the pavement and the cut-off piling includes a sheet rubber water stop and a backfilling of puddle clay under a 5ft. thickness of dumped rock. Where the paving abuts against the canyon walls, there is interposed a continuous sheet rubber water stop made up of tire fabric ¼in. thick and 36in. in width. This fabric is folded down into the space between the edge of the pavement and a curb of concrete set in each wall on a ledge cut for the purpose, the fabric being fastened to the curb and to the pavement. This flexible water stop will accommodate any settlement of the cofferdam as a whole, or any movement in the pavement.

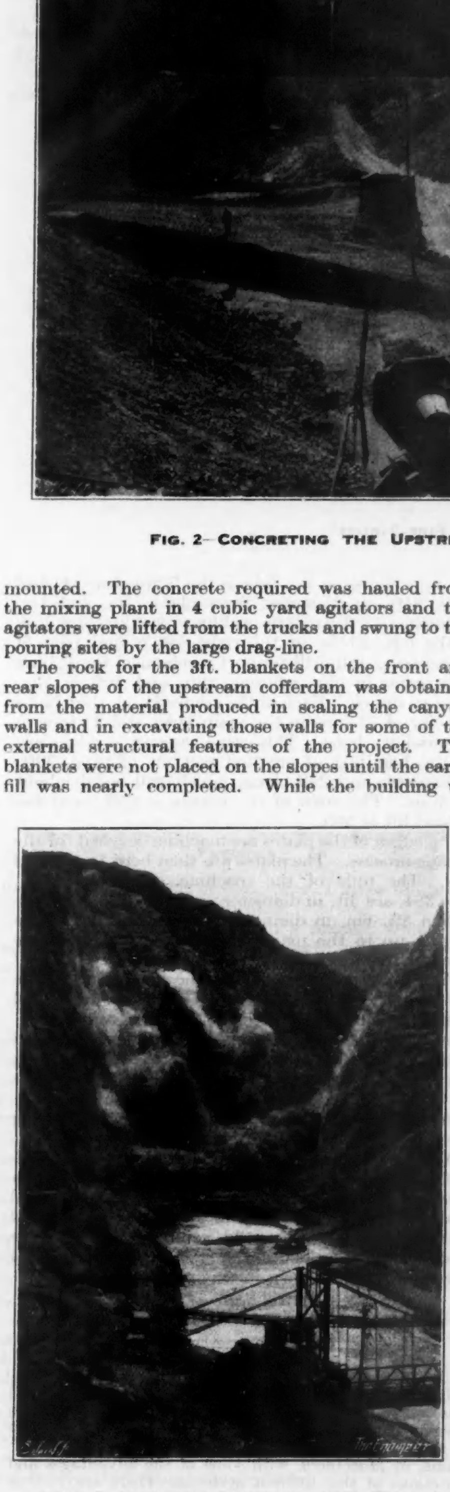

Fig. 3—Blasting Rock at Dam Site

In its finished state, the upper cofferdam is 480ft. long between the walls of the canyon, has a maximum height of 98ft., is 70ft. wide at the crest, and has a basal spread in cross section of 750ft. The crest of the dam is 13ft. above the assumed level of a maximum flood of 200,000 cubic feet per second. Before the construction of the upper cofferdam could be started it was necessary to excavate about 213,000 cubic yards of stream-bed deposit consisting for the most part of sand and gravel. Most of this material was transported upstream and dumped at the mouth of Hemenway Wash. The excavation for the upper cofferdam was started on September 25th and finished on December 5th, 1932. The earth fill was started on October 31st, 1932, and was completed on January 1st, 1933. The reinforced concrete pavement was placed between December 20th, 1932, and the end of February, 1933. The work was rushed in order to take advantage of the low-water period of the Colorado.

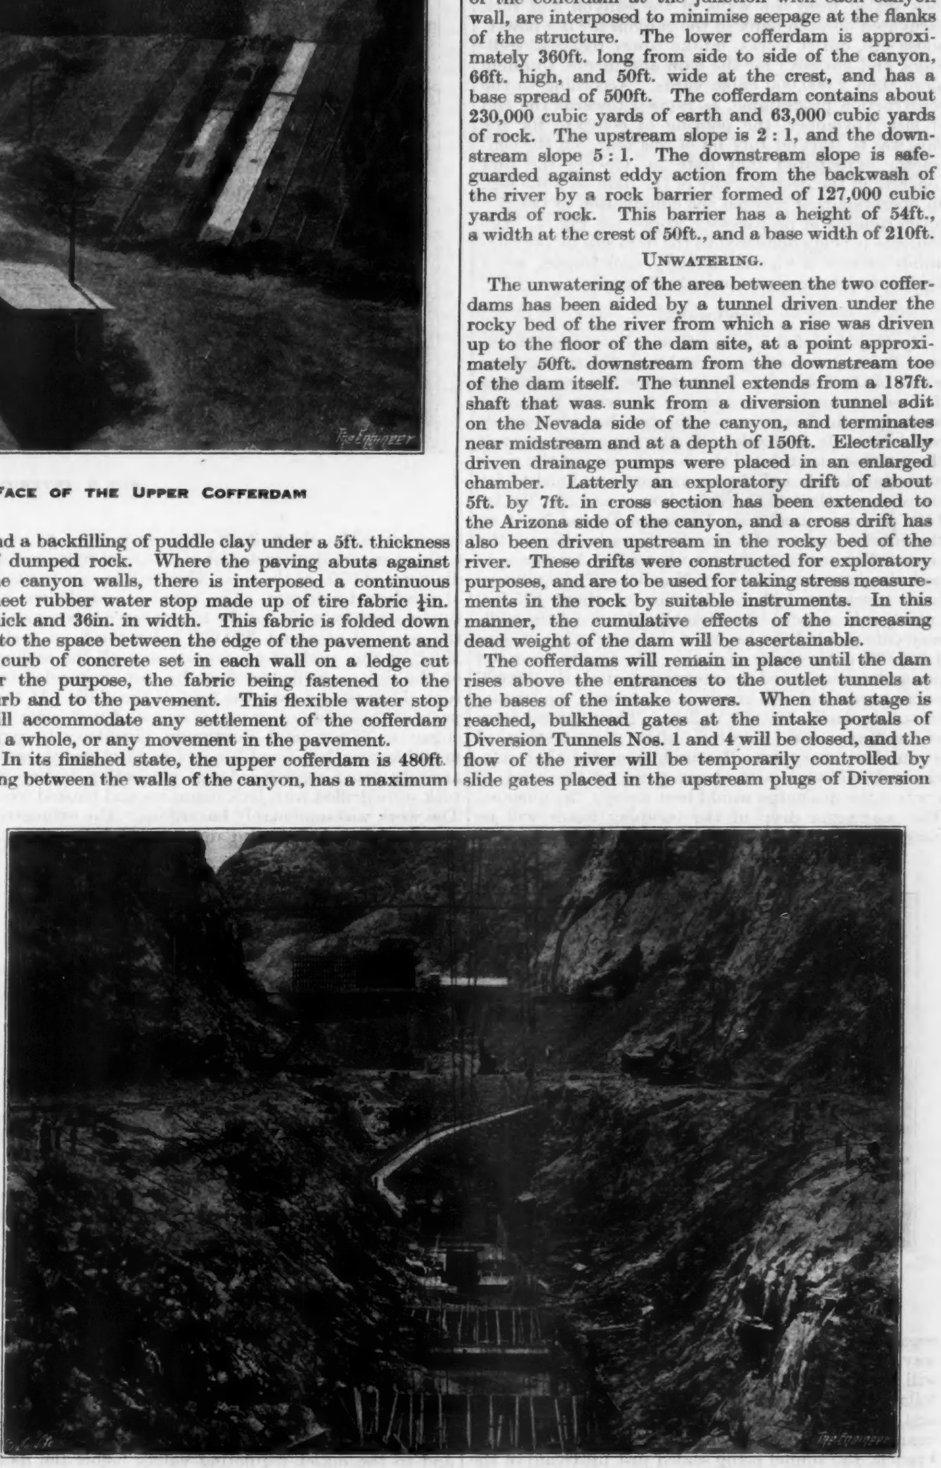

Fig. 4—Pouring Concrete for the Dam—June 6th, 1933

The Lower Cofferdam.

The construction of the lower cofferdam was delayed by scaling operations on the canyon walls and by excavations at the sites of certain of the outlet works, and also on the canyon walls. The earth-gravel fill for this cofferdam was also obtained from Hemenway Wash. The construction railway was extended downstream to a trestle near the dam site, where the material was dumped and then hauled by motor trucks to the cofferdam site. This cofferdam is protected on its upstream face by a 3ft. blanket of rock. The downstream face has no protective surfacing, nor has either slope a concrete pavement. Two concrete cut-offs, reaching from the base to the crest of the cofferdam at the junction with each canyon wall, are interposed to minimise seepage at the flanks of the structure. The lower cofferdam is approximately 360ft. long from side to side of the canyon, 66ft. high, and 50ft. wide at the crest, and has a base spread of 500ft. The cofferdam contains about 230,000 cubic yards of earth and 63,000 cubic yards of rock. The upstream slope is 2 : 1, and the downstream slope 5 : 1. The downstream slope is safeguarded against eddy action from the backwash of the river by a rock barrier formed of 127,000 cubic yards of rock. This barrier has a height of 54ft., a width at the crest of 50ft., and a base width of 210ft.

Unwatering.

The unwatering of the area between the two cofferdams has been aided by a tunnel driven under the rocky bed of the river from which a rise was driven up to the floor of the dam site, at a point approximately 50ft. downstream from the downstream toe of the dam itself. The tunnel extends from a 187ft. shaft that was sunk from a diversion tunnel adit on the Nevada side of the canyon, and terminates near midstream and at a depth of 150ft. Electrically driven drainage pumps were placed in an enlarged chamber. Latterly an exploratory drift of about 5ft. by 7ft. in cross section has been extended to the Arizona side of the canyon, and a cross drift has also been driven upstream in the rocky bed of the river. These drifts were constructed for exploratory purposes, and are to be used for taking stress measurements in the rock by suitable instruments. In this manner, the cumulative effects of the increasing dead weight of the dam will be ascertainable.

The cofferdams will remain in place until the dam rises above the entrances to the outlet tunnels at the bases of the intake towers. When that stage is reached, bulkhead gates at the intake portals of Diversion Tunnels Nos. 1 and 4 will be closed, and the flow of the river will be temporarily controlled by slide gates placed in the upstream plugs of Diversion Tunnels Nos. 2 and 3. The upper cofferdam will then be overtopped by the water in the reservoir impounded by the dam. The lower cofferdam and its rock barrier are then to be removed to clear the river channel and the tail-race for the efficient operation of the power plant.

Foundations.

Between the two cofferdams, starting at the downstream toe of the main cofferdam, the contractor was called upon to expose the rocky bed of the river for an average width of 450ft. and for a distance of 1200ft. to ascertain the exact condition of the rock preparatory to excavating the area to be occupied by the foundation of the dam. The work of making the dam site alone ready for the pouring of concrete involved the drilling, blasting, and removal of more than 100,000 cubic yards of rock—see Fig. 3. All excavated material was transported by motor trucks from the unwatered area, up a broad roadway on the downstream slope of the upper cofferdam, and dumped at loading docks a few hundred yards away. From that point the material was moved to Hemenway Wash by trains or used to widen the railway embankment on the Nevada side of the river. Many of the trucks were fitted with duralumin bodies and were capable of hauling unit loads of 16 cubic yards. The trucks moved in a continuous procession, night and day, and at times as many as 7000 truckloads were disposed of in the course of twenty-four hours.

It should be borne in mind that the quantity of rock to be removed within the unwatered area included rock scaled from the walls of the canyon and rock excavated on each flank of the canyon for the powerhouse site, outlet works, intake tower recesses, spillways, and keyways for the dam abutments, totalling more than 2,000,000 cubic yards. According to the construction programme, as revised towards the end of last November, the pouring of concrete for the dam was to start on July 1st of this year, but the contractor anticipated that date by placing the first concrete in the deep keyway of the dam on June 6th, an operation that marked the culmination of twenty-seven months of preparatory work—see Fig. 4. The concrete is being delivered to the dam site by bottom-dump buckets of 8 yards capacity, each bucket, when loaded, weighing approximately 20 tons.

SPILLWAYS.

By May 1st of this year all four diversion tunnels were finished and ready to deal with the spring flood water of the Colorado. At that time the two Arizona diversion tunnels were carrying the whole flow, and on forty-eight hours' notice the two Nevada tunnels could be made available. By the same date most of the penstock tunnels on the Nevada side of the river were completed, and the excavation was finished for six of the outlets to the valve house, and the 7ft. by 14ft. pioneer tunnel from Diversion Tunnel No. 2 to the intake tower—also on the Nevada side of the river. The corresponding work on the Arizona side had also been excavated by May 1st. The spillways have necessitated the excavation of about 625,000 cubic yards of rock. As originally planned,[†] the spillway cuts would have required the excavation of over 1,000,000 cubic yards of rock. The finally accepted design has thus saved the excavating of nearly 400,000 cubic yards and will result in economies amounting to substantially 500,000 dollars. The adopted form of spillway was selected after the testing of a number of types. Research disclosed that side-channel spillways with drum gates at the crest to control the discharge would best answer the purpose. The maximum drop of the escaping water will be nearly 530ft., and in that descent the water would reach a velocity of 175ft. per second. In each spillway, as now under construction, the released water will flow over a 26ft. weir, make a 90 deg. turn, then follow a descending channel parallel with the weir, and finally enter an inclined shaft 600ft. long that connects at the bottom with one of the 50ft. diversion tunnels, the tunnel being sealed just upstream of the junction by a concrete plug. Each spillway cut is 650ft. long and each spillway is to be equipped with four drum gates, 100ft. long and 16ft. in diameter. The spillway cuts are to be lined with 24in. of reinforced concrete. The spillway floors slope toward their discharge shafts on a gradient of 1 in 10.

The inclined tunnels connecting with the spillways were driven from their respective diversion tunnels by top-centre headings 7ft. high and 14ft. wide. The succeeding enlargement operation will be postponed in the case of the Arizona tunnel until Diversion Tunnel No. 3—now carrying water—becomes available for the conclusion of the work. The inclined spillway tunnel on the Nevada side was deepened by successive benching, the rock removed during the enlargement being disposed of by dropping it down into the diversion tunnel, from which it was removed.

INTAKE TOWERS.

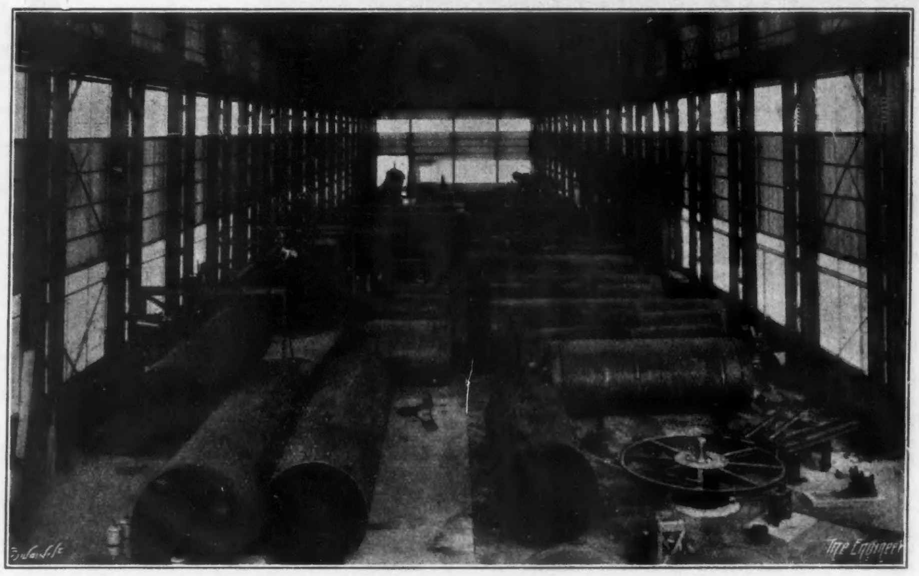

FIG. 6—INTERIOR OF PIPE-HOUSE

Two spectacular phases of rock work have been those associated with the scaling of the canyon walls and with the excavation of the shelves and the deep recesses that are to receive the four intake towers. These towers will control ultimately the flow of all water from the reservoir other than that escaping at flood periods by way of the spillways. Each of these towers is to be about 390ft. high from base to top, with an external diameter at the base of 82ft. and a diameter of 67ft. at the top. They will be constructed of reinforced concrete. The recesses and shelves in the two canyon walls for the towers have necessitated the removal of about 320,000 cubic yards of rock. Much of this work of excavation and all the scaling on the canyon walls was done by men suspended by rope slings passed over the tops of the cliffs. At the peak of these activities many scores of men were so engaged. They used duralumin pinchbars to pry unstable rock loose and air jets to blow away small and shattered masses. Large projecting bodies of rock were drilled with jack hammers and blasted free. The work was undeniably hazardous. The estimated amount of rock removed during scaling operations has been put at 150,000 cubic yards. Scaling is now finished.

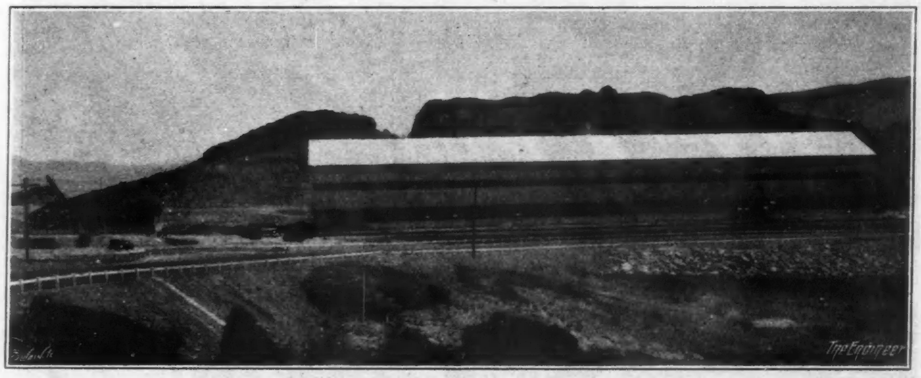

FIG. 5—PIPE FABRICATING HOUSE ADJACENT TO BLACK CANYON

FABRICATION OF STEEL CONDUITS.

From each of the four intake towers a steel pipe, 30ft. in diameter, will convey water for the turbines and to the outlet regulating valves below the dam. From each of the 30ft. pipes four 13ft. diameter penstocks—that is, sixteen in all—will feed the turbines, one penstock being branched at its end to serve two turbines. The 30ft. pipes, which vary between 1030ft. and 1280ft. in length, will be extended by 25ft. pipes to the four outlet stations, which will be served by groups of pipes, 8ft. 6in. in diameter.

The contract for these steel pipes was given to the Babcock and Wilcox Company, of New York, and since the conveyance of such large parts over long distances was out of the question, a special plant for their manufacture was erected on the rocky slopes above the Canyon. The pipes, as completed, are being handled by the cableway to be described later. A general view of the pipe-house is reproduced in Fig. 5 and other views are given on page 384.

This plant is fully equipped to fabricate by fusion welding, and to test by X-ray, 14,500ft. of pipe, 8½ft. to 30ft. in diameter, from steel plate ranging in thickness from ⅞in. to 2¾in. Approximately 400,000 linear feet of welding will be performed in the fabrication of these pipes. The shop building is 520ft. long by 90ft. wide, and is 56ft. high from the floor to the bottom chord of the roof trusses. The total floor space, including that of a laboratory and foreman's office contained in a lean-to on one side of the shop, is 51,500 square feet.

In the interior view of the plant (Fig. 6) the work seen in progress on the floor is the fabrication of steel pipes, 8½ft. in diameter, from plates ⅞in. and 1in. in thickness. Automatic welding machines are seen on the left, whilst in the right foreground part of the indexing and drill-support mechanism for drilling girth seams in pipe sections, 25ft. and 30ft. in diameter, is shown. Each of the cranes in the shop has a capacity of 75 tons in the main hoist and 25 tons in the auxiliary hoist. This crane capacity is necessary for the handling of erection sections of pipe, 30ft. in diameter and 24ft. long, which will weigh about 150 tons. The span of the cranes is 85ft., and the vertical lift is 50ft.

The edges of the plates are machine bevelled for the welding process. The plates are then bent in vertical rolls. The rolls of the machine, shown in Fig. 7, page 384, are 3ft. in diameter and 12ft. high. A pipe section 8ft. 6in. in diameter is being rolled. Plates ranging up to the maximum thickness of 2¾in. are rolled in this machine.

Fig. 8 on page 384 shows the machining of the end of an 8½ft. pipe section. A large horizontal boring machine is to be seen in the background.

In Fig. 9 the mounting of two pipes 8½ft. in diameter on rolls under an automatic fusion welding machine, preparatory to welding a girth seam, is shown. The spider for holding the seam in alignment and constituting a backing member for welding is seen within the section.

A section of an 8½ft. pipe, mounted under an automatic fusion welding machine, for the welding of the longitudinal seam, is shown in Fig. 10. The general quality of each weld is indicated by the physical characteristics of the weld joining the end-piece specimens tack-welded to the pipe sections at one end of each seam, as shown in this photograph.

(To be continued.)

[†] Compare Fig. 1 herewith with Fig. 5, page 582, of our issue of December 9th, 1932.

Now that thread grinding is beginning to be considered as an essential process in good engineering work, it becomes necessary for those responsible for the selection of plant for this purpose to acquaint themselves, says Mr. H. F. Atkins, in *Machinery*, with some of the advantages and limitations of the different systems. There are various multi-ribbed wheel machines and machines designed for using single-ribbed wheels. While the single-ribbed wheel cannot remove as much metal in a given time as a multi-ribbed wheel, it is much more quickly dressed and re-dressed; it is changed from one pitch to another without removal and consequent risk of damage; the shape of the thread is more easily controlled; the pitch is more regular and correct, as there are less conflicting elements; there is less heat produced with its detrimental effect on pitch and truth; and it is adaptable to threads such as the Acme that cannot be ground with multi-ribbed wheels. Further, the correct form of Whitworth thread is better maintained. For a variety of work the single-rib wheel is preferable to a multi-rib type, and if the output warrants it, may be used in conjunction with machines of lower capital cost which rough out the thread.

Heat Transfer in Electric Furnaces.

By E. G. FIEGEHEN, M.I. Mech. E.

It is proposed in the present article to investigate the approximate distribution of heat in electric resistor type furnaces, used for the annealing and heat treatment of steel castings. Such furnaces are generally run at about 1750 deg. Fah., the maximum temperature desired in the castings being about 1650 deg. Fah.

We will take as an example a car type annealing furnace, having a hearth 20ft. long by 9ft. wide, and handling side-frame castings for box cars weighing from 500 lb. to 600 lb. each and requiring, according to their metal thickness, an annealing period of about 60 minutes, followed by a soaking period of 30–45 minutes.

The wall construction consists of 9in. of fire-brick, backed by 5in. of insulation and encased in a plated shell. It will be assumed for simplicity that the same brick construction is used for the furnace roof, car platform and end doors, of which there are two, to facilitate the transfer of cars. Fig. 1 gives the principal dimensions of this furnace.

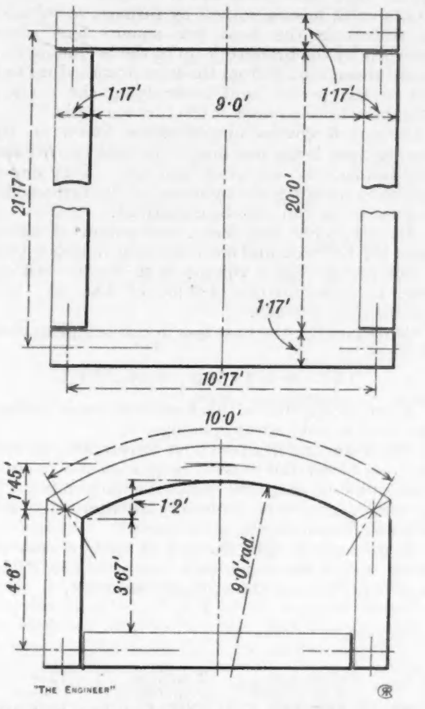

FIG. 1—DIMENSIONS OF ELECTRIC ANNEALING FURNACE

The normal loading of such a furnace would be about 60 lb. per square foot of hearth area per hour; in this case

$$60 \times 9 \times 20 = 10{,}800, \text{ say, } 11{,}000 \text{ lb.}$$

Upon completion of the annealing period the heated car with its load is pulled out at one end of the furnace, whilst a loaded car of cold castings is pulled in at the other end, the cars being coupled together for the purpose. During this operation current is turned off and the temperature of the surface of the furnace walls falls appreciably, which happens to be an advantage. Castings of appreciable thickness of metal are liable to crack if introduced into a fully heated furnace, causing a heat gradient in the thickness of the metal in excess of the safe limit, which is approximately 20 deg. to 25 deg. Fah. temperature difference per inch of penetration for soft steel, and the heat input has to be regulated to keep the rate of temperature rise within this limit.

In the present case, however, the thicknesses of the castings range around ¾in., and no risk is incurred in this respect. The introduction of the cold castings causes the surface temperature of the furnace walls to drop still lower, and by the time that the doors have been closed and sealed by sand, the current may be turned on, for, owing to the presence of the cold castings, the resistors will take several minutes to reach normal working temperature.

Furnace Walls.

We will now turn our attention to the transfer of heat to the furnace walls.

In the early stages of heating we shall find that these absorb heat at a rate which is extremely great compared to the average rate of transfer over an extended period.

The study of heat transfer in refractories by mathematical means is exceedingly difficult and tedious, even when the variation of the coefficients of specific heat and conductivity with temperature are ignored. Fortunately, a graphical method[*] of finding the relation of temperature, space, and time has been devised, whereby the temperature variation in a conductor, such as a furnace wall, with regard to time can be investigated quite simply, and with sufficient accuracy for all commercial purposes.

Fig. 2 illustrates the application of this graphic construction to the case in hand.

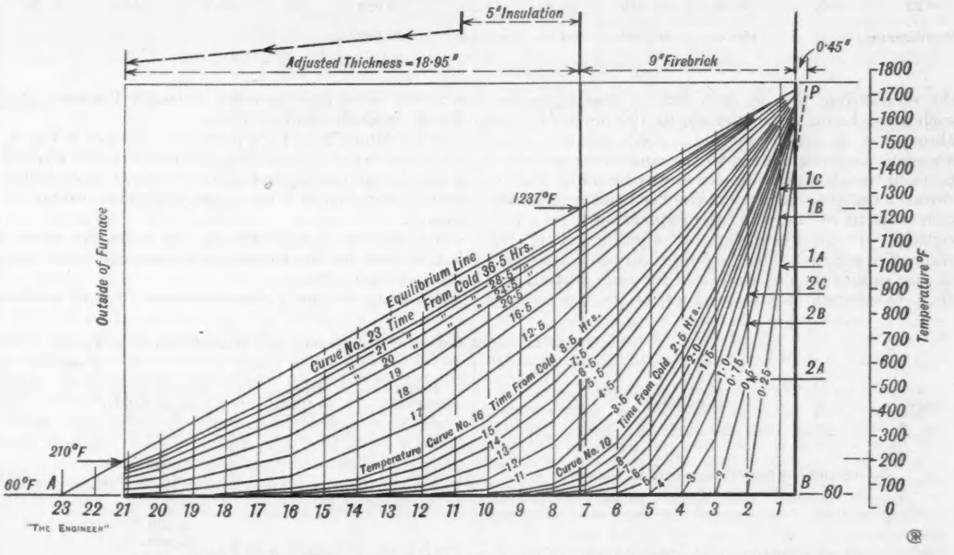

FIG. 2—GRAPHICAL METHOD OF STUDYING HEAT TRANSFER IN A FURNACE

For the purpose of this article, it is thought inadvisable to complicate the construction by adjustments to take care of varying specific heat and conductivity of fire-brick, but we may remark that this can be done quite simply when the result justifies the additional work.

Referring to Fig. 2 it will be noted that whilst the fire-brick thickness is drawn correctly to scale, that of the insulation is shown to a scale nearly four times as great The reason for this lies in the fact that the conductivity of the insulation is only about one-fourth that of fire-brick per unit of thickness, or, in other words, its resistance to heat transfer is four times as great as that of fire-brick. If, therefore, we draw the insulation approximately four times its actual thickness, we may consider it replaced, for the purposes of the diagram, by fire-brick of equivalent heat resistance, and the whole of the wall can be treated as if it were composed entirely of fire-brick.

The exact equivalent thickness is found as under:—

Let T_b be the temperature of the wall at the junction of the fire-brick and the insulation, when the furnace face of the fire-brick is at a temperature of, say, 1700 deg. Fah. From test results of walls of this construction, under such conditions, we find that the outer face of the insulation will, at equilibrium, attain a temperature of 210 deg. Fah. Then, using the usual formula:—

$$\frac{1700-T_b}{T_b-210}=\frac{9\text{in. (thickness of fire-brick)}}{5\text{in. (thickness of insulation)}}\times\frac{1\text{ (relative conductivity of insulation)}}{4\text{ (relative conductivity of fire-brick)}}$$

whence $T_b=1237$ deg. Fah.

This is a point on the equilibrium line of heat transfer in the wall, when fully heated. The upper end of this line cuts the 1750 deg. Fah. temperature level at a point whose distance from the inner face of the furnace wall and to the right of this is found by the formula relating to this construction

$$P_d=\frac{C}{K_2}=\frac{0\cdot75}{20}=0\cdot375\text{ft.}=0\cdot45\text{in.}$$

where

C = conductivity of fire-brick (B.Th.U. per square foot per hour per deg. Fah. per foot thickness),

K_2 = coefficient of heat transfer to face of fire-brick (B.Th.U. per square foot per deg. Fah. per hour).

Now join this "pole point" P with the equilibrium point (1237 deg. Fah.) already found and produce to cut the base line at 60 deg. Fah. Intersect the lower end of this line by a horizontal, drawn from the temperature scale at 210 deg. Fah. This is the lower equilibrium point for the wall.

At the intersection draw a vertical, which will represent the outer face of the insulation and indicate its corrected thickness.

Divide the base line A–B into $n+\frac{1}{2}$ spaces and erect ordinates commencing half a space from the point B and proceeding to the left ending at A.

Obviously the smaller the subdivisions the greater the accuracy obtainable, as will be seen later. The present base line has been divided into 22½ parts to obtain a clear diagram.

We have now to construct time-temperature curves, each of which will represent, graphically, the temperature distribution in the wall at the end of a definite time interval from a start from cold.

We will assume (what is practically true in this application) that the furnace face of the wall is exposed, continuously, to the full furnace temperature of 1750 deg. Fah.

Number the ordinates 1–23 from the right. Join pole point P with the base of No. 2 ordinate; this is our first temperature distribution curve.

To find the time interval $d\,t$ from cold that it represents, we use the formula:—

$$d\,t=\frac{(d\,s)^2\times q\times w}{2\times C}\cdot\text{hours}$$

wherein

$d\,s$ = spacing of ordinates (in this case 1·365in. = 0·1137ft.)

q = specific density of fire-brick (125 lb. per square foot),

w = mean specific heat of fire-brick (0·235),

C = conductivity of fire-brick, 1ft. thick (0·75).

We have then

$$d\,t=\frac{(0\cdot1137)^2\times125\times0\cdot235}{2\times0\cdot75}$$

$$=0\cdot253\text{ hour—say, }\tfrac{1}{4}\text{ hour.}$$

Each successive curve, constructed on the ordinate spacing adopted, will represent an additional lapse of ¼ hour from cold; for instance, curve No. 5 represents conditions 1¼ hour from cold start.

Proceeding, the second curve starts at the foot of ordinate 3 by a line drawn upwards in the direction of point 1*a*, until it meets ordinate 2; thence it is continued to meet pole point P.

Curve No. 3 (¾ hour from cold) starts at the foot of ordinate 4 and is drawn, in the direction of intersection 2*a*, until it meets ordinate 3; thence, in the direction of intersection 1*b*, until it meets ordinate 2, and thence straight to pole point P.

Thus each successive curve, starting from the base of the appropriate ordinate, is drawn upwards, in the direction of the intersection of the previous curve with the second ordinate to the right of the starting point, until it reaches the adjacent ordinate to the right, when it changes direction to point to the intersection of the previous curve with the second ordinate now on its right, stopping again at its adjacent ordinate on the right and again changing direction as before.

The last chord of a curve always connects the point where it intersects ordinate 1 and the pole point P.

A study of the diagram will indicate the method clearly.

The geometry on which this construction is based and the formulæ used are very simple indeed, and for these the reader is referred to Professor Trinks' excellent book.

The curves continuously fall closer to one another and, to avoid crowding on the diagram, the same construction may proceed using two-ordinate intervals ($2\,d\,s$).

It is evident from the formula (involving $(d\,s)^2$) that the time interval will be thereby quadrupled. When the curves crowd once more, the spacing or ordinates may again be doubled ($4\,d\,s$) and the time interval will once more be quadrupled.

In the figure, curves 1–10 will be seen to be constructed at ordinate intervals, curves 11–16 are at double ordinate intervals, and the upper group are at four ordinate intervals. The change in construction can be plainly seen, the chords of the curves doubling in length with each change.

On each curve is marked the time interval, from cold, that it represents.

---

[*] Trinks, "Industrial Furnaces," Part I.

Obviously the real distribution would follow smooth curves, but the polygonal lines, given by this construction, serve the purpose sufficiently well, considering the possible variation of many of the factors in the problem.

The "equilibrium line" represents temperature conditions after a steady state of heat transfer in the wall is finally reached if the heating continues for several days.

Heat Absorption.

To study the heat absorption of the fire-brick and insulation, in relation to elapsed time, the area under the equilibrium line in each section was measured, such areas being proportionate to 100 per cent. heat absorption in each section. The relative heat absorption corresponding to the conditions indicated by each time temperature curve was found by finding the area under each curve in the fire-brick and insulation sections of the wall, and expressing it as a percentage of the absorption at equilibrium in the respective section. The "equilibrium heat capacity" of one square foot of wall area for each section was then calculated as the product of its weight (per square foot of wall), its mean specific heat and the mean temperature rise from 60 deg. Fah.; the result is shown in columns 4 and 6 of Table I. opposite the reference "equilibrium."

Equilibrium	—	100·0	32,500	100·0	1,380	33,880				

The heat absorption represented by the various curves was calculated by multiplying this figure by the appropriate percentage of area under the curve, related to that under the equilibrium line in each section and appears in the same columns of Table I; totals of these figures appearing in column 7 of the table, give the heat absorption for the entire wall at the successive stages.

In Fig. 2 it will be noted that not until we reach curve No. 17 (12·5 hours from start) does heat actually reach the outer face of the insulation. Up to that point the flow of heat has been entirely absorbed by the material of the wall. The succeeding curves emerge at increasing heights, indicating corresponding outside wall temperature. From these the heat emission by radiation and convection from the hot surface per square foot of wall has been calculated, and is shown in column 10. Column 11 is the total of figures in columns 7 and 10, and thus represents the total heat transfer, through 1 square foot of wall, from the source of heat.

These values have been plotted as a curve in Fig. 3, which was drawn as a fair approximation to the plotted points; closer correspondence is hardly to be expected when the "curves" used are polygonal instead of smooth.

We are now in a position to estimate the absorption of heat by the furnace after any specified time interval from cold.

Referring to Fig. 1 measurements of wall surface area will be taken on the median lines in the wall thickness, as indicated.

Thus we have :—

Floor area = 10·17 × 21·17	= 215	sq. feet
Roof area = 10·0 × 21·17	= 212	„
Two side walls = 2 × 21·17 × 4·6.. ..	= 200	„
Two doors = { 2 × 4·6 × 10·17 ..	= 93	„
+ 2 × ⅔ × 1·45 × 10·17	= 20	„
	740	„

We could use the method of Fig. 2 with appropriate constants to investigate the rate at which the 11,000 lb. of steel castings will receive heat during the annealing period of 60 minutes. This, however, would not be of great interest, owing to the moderate thickness in this case.

The total heat required to raise the charge of castings to the annealing temperature of 1650 deg. Fah. is

11,000×250 (B.Th.U. in 1 lb. of steel raised from 60 deg. to 1650 deg. Fah.)=2,750,000 B.Th.U.

Electricity Consumption.

We now come to the electrical aspect of the problem. We have

1 kilowatt-hour=3412 B.Th.U.

Since the steel absorbs 2,750,000 B.Th.U., in a heat of one hour duration, then the net kilowatt capacity required for this alone is

2,750,000/3412=806 kilowatts.

Table II. has been prepared to show the heat requirements of the furnace and the electrical input at various times from a cold start and for usual working conditions.

Column 4, heat required by steel charge, has already been calculated, and is constant.

Column 5, heat absorbed by furnace, is calculated by deducting the heat per square foot already absorbed by the brickwork up to the beginning of the period (from Fig. 3) from the heat absorbed up to the end of the period, and multiplying the result by 740, the estimated area of the furnace walls.

Column 6 covers miscellaneous losses of heat. Among these is the loss due to the heat carried out of the furnace by escaping hot air. This depends primarily upon the air-tightness of the furnace doors and seals, and can only be guessed at.

At, say, 1700 deg. Fah., one pound of air contains 457 B.Th.U., and one cubic foot weighs 0·018 lb.

The furnace has a volume of 40·2×20=804 cubic feet, or 804×0·018=14·7 lb. of hot air, whose specific heat is 0·269.

Consequently, the heat loss in one complete change of air is

14·7×0·269×1640=6500 B.Th.U.

There are no flues in this furnace to cause a draught and suck in cold air at openings.

When starting from cold, air convection will induce cold air below the middle height of the doors and expel it above that line, but as the temperature of the furnace begins to be uniformly distributed, this flow will be reduced to a small amount.

If we assume eight changes of air in a heat of 1½ hours, this corresponds to a loss of 52,000 B.Th.U., say, 12 per cent. of the average heat input.

Table II.—*Heat Requirement of Furnace and Electrical Input for Various Working Conditions.*

Case.	Conditions.	Hours from cold start.	Heat to steel, B.Th.U.	Heat to furnace (from chart), B.Th.U.	Miscellaneous losses, say, 12 per cent.	Radiation loss, one door open 10 min., B.Th.U.	Total heat required, B.Th.U.	Electrical input, kilowatts.
A.	Empty furnace heated from cold in 4 hours	1–4	—	21,000×740 =15,550,000	1,865,000	—	17,415,000	17,415,000 3412×4 =1278 kW
B.	First heat of 1½ hours	4–5½	2,750,000	23,200 21,000 2,200×740 =1,630,000	527,000	238,500	5,145,500	5,145,500 3412×1·5 =1005 kW
C.	Second heat of 1½ hours..	5½–7	2,750,000	25,000 23,200 1,800×740 =1,330,000	490,000	238,500	4,808,500	4,808,500 3412×1·5 =940 kW
D.	Third heat of 1½ hours	7–8½	2,750,000	26,300 25,000 1,300×740 =963,000	446,000	238,500	4,397,500	4,397,500 3412×1·5 =861 kW
E.	Fourth heat of 1½ hours..	8½–10	2,750,000	27,400 26,300 1,100×740 =814,000	428,000	238,500	4,230,500	4,230,500 3412×1·5 =851 kW
F.	Fifth heat of 1½ hours	10–11½	2,750,000	28,300 27,400 900×740 =666,000	409,000	238,500	4,063,500	4,063,500 3412×1·5 =794 kW
G.	Heating up empty furnace which has retained 30 per cent. of its heat over week-end	4 hours to heat up	—	0·60×21,000×740 =9,300,000	1,117,000	—	10,417,000	10,417,000 3412×4 =764 kW
H.	Alternative to "A" heat up empty furnace from cold in 6 hours	1–6	—	23,900×740 =17,650,000	2,120,000	—	19,770,000	19,770,000 3412×6 =969 kW

Column 7 contains an estimate of the heat loss when the end doors are open whilst changing cars.

In this process, one door is fully opened, for the passage of the heated car, the other door being fully opened for the entry of the cold car, which is coupled to the back end of the hot car. As soon as the cold car is in position, both doors are closed on their end seals. The doors are generally air-operated and the cars pulled by power, so that an interval of 5 minutes with both doors open, equivalent to 10 minutes' radiation from one door, should cover the heat loss from this source and minor incidental losses.

The radiation loss is expressed by the formula :—

$$\text{B.Th.U. per hour} = 0\cdot15 \times A \left[\left(\frac{T_f}{100}\right)^4 - \left(\frac{T_a}{100}\right)^4\right]$$

T_f and T_a being the absolute temperature deg. Fah. of the furnace and air respectively. A is the area of the opening in square feet. This works out to

$$\text{B.Th.U. for 10 minutes} = \tfrac{1}{6} \times 0\cdot15 \times 40\cdot2$$
$$[(22\cdot1)^4 - (5\cdot2)^4] = 238{,}500 \text{ B.Th.U.}$$

This amount of heat has, of course, to be restored to the walls during the progress of the next heat.

Now examining Table II., we observe that the heat requirements steadily fall as the day advances, this being due to the furnace walls approaching the state of heat equilibrium. This is very marked in Column 5.

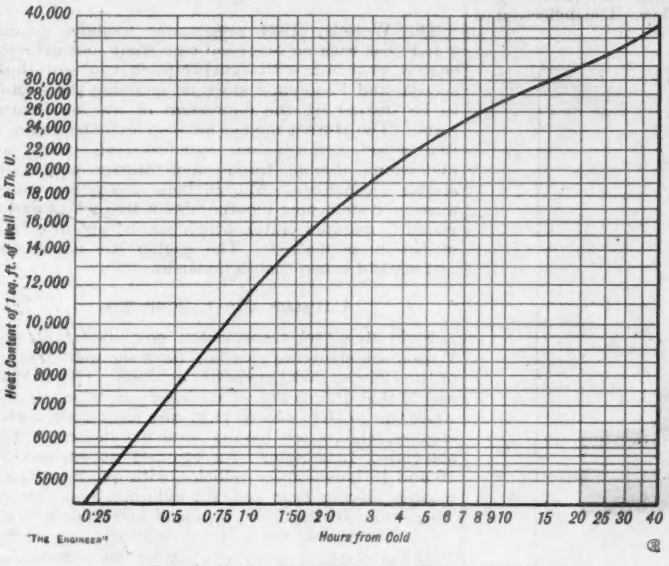

Fig. 3—Heat Absorbed by Brickwork

Now with regard to the electrical input required, it is undesirable to have this too great, having regard to cost of installation, demand factor, and efficiency of utilisation. On the other hand, the annealing process is doubtless part of a definite production cycle and the time per heat cannot be varied to a great extent. It would seem that in the present case a connection of about 950 kW would be most suitable. After week-end shutdowns, case H would be representative and case B could be extended to, say, 1 hour 40 minutes to reduce the demand to this figure. After a repair or a long shutdown, case A would apply, and it would be necessary to start earlier and extend the heat over about 5½ hours.

The estimated B.O.T. units (kilowatt-hours) in each case is as follows :—

Case A	5100	Case E..	1240
Case B	1520	Case F	1190
Case C..	1410	Case G..	2950
Case D	1280	Case H	5780

In connection with cases A, G, and H it may be asked: "When is a furnace to be considered as 'heated up'?" An American writer† has stated that a furnace may be considered as "heated up" for practical purposes when the temperature in the fire-brick at a depth of 2in. below the furnace face has attained a temperature which is 75 per cent. of the normal temperature of the furnace, this conclusion being reached after a series of practical tests. It will be seen from Fig. 2 that this corresponds with the present construction to curve No. 11 (3·5 hours from cold start).

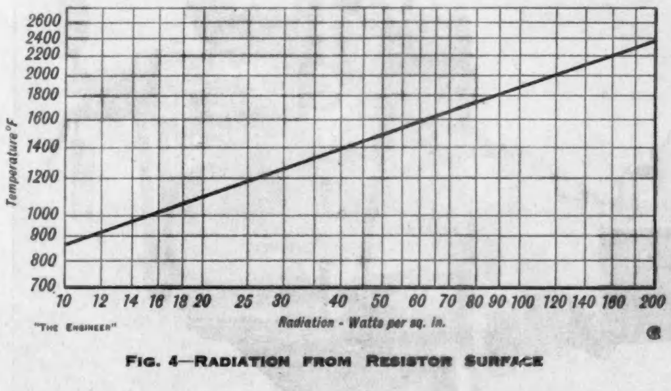

Fig. 4—Radiation from Resistor Surface

In fuel-fired furnaces a certain amount of overload capacity may be secured by burning more than the normal amount of fuel, perhaps at the expense of efficiency; but in the electric resistor type furnace the heat output is strictly limited by the constant voltage of the supply and the resistance of the resistors at furnace temperature.

In this connection one point should be noted that has a bearing upon the kilowatt capacity desirable. We have spoken of an "annealing period" and a "soaking period." In the case of thin castings the heat penetrates so fast relatively that these periods are indistinguishable, but take a thick casting; at the end of the "annealing period" the surface is supposed to be up to temperature and the pyrometer-controlled gear operates to reduce the heat input to that required to complete the penetration of heat to the centre of the casting thickness and some additional heat to the walls and to replace losses.

It is nearly as undesirable to have excessive kilowatt capacity connected to a furnace as to be underpowered, for it results in too frequent operation of the automatic heat control gear.

The interaction of radiation from the resistors and from the furnace is interesting. Fig. 4 shows watts radiation per square inch of resistor surface at various temperatures. Furnace resistors are generally rated to emit about 12 watts per square inch in normal working.

It will be seen from the chart that when exposed to room temperature only they attain this rate of emission at a resistor temperature of approximately 916 deg. Fah. Since the connected kilowatt capacity will not provide more than this normal demand of 12 watts per square inch, what happens when, in the furnace, they attain a temperature of 1750 deg. Fah. and by virtue of being at that temperature radiate at the rate of about 79·4 watts per square inch ?

The reason for this is that radiation is universal. All bodies hot and cold (down to the temperature of absolute zero −460 deg. Fah.) radiate heat in proportion to the fourth power of their absolute temperature. When two bodies are in range of each other the radiation is mutual. The resistor radiates to the furnace and its contents, according to its absolute temperature (as shown by Fig. 4) and at the same time the furnace radiates heat back to the resistor, according to the absolute temperature of the furnace. The resulting heat exchange corresponds to the difference in intensity of radiation.

The conditions are comparable with pressure and back pressure of fluids. In a pipe subject at one end to 80 lb. per square inch pressure and operating against 68 lb. per square inch back pressure the flow of fluid will correspond to an effective pressure of 12 lb. per square inch.

A resistor at 1750 deg. Fah., radiating, therefore, 79·4 watts per square inch, will be in heat equilibrium in a furnace which is radiating back to it heat energy at the rate of 67·4 watts per square inch, when supplied with the difference of 12 watts per square inch by its electricity supply. The furnace temperature corresponding to the above is 1658 deg. Fah.

The resistor cannot get any hotter than 1750 deg. Fah. under the above conditions, since it cannot draw further energy from the electricity supply to do so, but let the furnace cool to, say, 1483 deg. Fah., corresponding to a reduced radiation of 47·8 watts per square inch, then the resistor must correspondingly drop in temperature until it is radiating 12 watts per square inch in excess of this or 59·8 watts per square inch, corresponding to a temperature of 1580 deg. Fah. This automatic adjustment may be witnessed by bringing a cold mass of metal close to a heated resistor element (say, of a household appliance) which immediately loses its glow in the act of adjusting its emission to the amount of electric energy that it is receiving.

Conclusion.

Electric heating is becoming increasingly popular on account of its high efficiency, ease of control, cleanliness and the maintenance of a neutral atmosphere in the furnace, reducing scaling to a minimum. Furthermore, the maintenance of the refractories is much less, owing to the absence of flame and its scouring action.

In many localities, notably in Canada and America, off-peak power in large blocks for industrial purposes can be purchased at such low rates as to compete, at least on equal terms, with oil or coal firing, and such loads are welcomed by the power companies, since, being non-inductive, they have unity power factor and the heavy demand improves the load factor of the station.

The average oil-fired annealing furnace, without recuperation, has an overall efficiency of approximately 25 per cent. only, and of the total heat input about 50 per cent. escapes to the stack, for the gases must leave the furnace hotter than the charge. As a result of the low efficiency only 12–13 per cent. of the whole heat supplied goes to heat up the brickwork, and its rate of transfer becomes of minor importance. In the electric furnace there is no stack and the loss of heat in escaping gases is relatively small, consequently a much larger proportion of the heat input is absorbed by the brickwork, as can be seen by reference to Table II., and this matter becomes of sufficient importance to repay investigation.

It is hoped that a little light may have been shed on this matter in the present article.

The Quarter's Shipbuilding Returns.

The statistics issued by Lloyd's Register of Shipping regarding merchant vessels under construction at the end of September last show that in Great Britain and Ireland there is an increase of 16,260 tons in the work in hand as compared with the low figures for the previous quarter, and also that the present total—303,762 tons—is 65,329 tons greater than the tonnage which was being built at the end of September, 1932. An encouraging feature of the returns is the fact that, while at the end of September the tonnage on which work is suspended was identical with that at the end of June—about 134,000 tons of steamers and 6000 tons of motorships—the total of the tonnage now on the stocks maintains the upward trend which has been observable since the beginning of the year. About 57,000 tons—19 per cent. of the tonnage now being built in this country—is intended for registration abroad or for sale.

The tonnage now under construction abroad—452,990 tons—is about 8000 tons more than the work which was in hand at the end of June, 1933. This increment of the quarterly total of tonnage being built abroad is the first to be recorded since June, 1930. Tonnage, included in the total in hand abroad, on which work has been suspended amounts only to 1860 tons of steamers and 34,953 tons of motorships. The four leading countries abroad are :—France, 95,838 tons ; Japan, 85,570 tons ; Sweden, 71,440 tons ; and Holland, 40,862 tons. The total tonnage under construction in the world amounts to 756,752 tons, of which 40·1 per cent. is being built in Great Britain and Ireland, and 59·9 per cent. abroad. The total for the world at the end of September is higher than that at June 30th by 24,257 tons, which is the first quarterly increase in the world total to be noted for 3½ years.

In Great Britain and Ireland, 39,670 tons were commenced during the last three months. While this figure is 10,380 tons less than the corresponding total for the June quarter, with one exception it is larger than any quarterly total during the years 1931 and 1932. During the quarter ended September, 1933, 42,077 tons were launched in Great Britain and Ireland, showing an increase of 31,041 tons as compared with the June quarter. Similar figures for abroad are 71,102 tons commenced, and 90,233 tons launched, showing increases, as compared with the previous quarter, of 222 tons in the tonnage commenced, and 21,945 tons in the tonnage launched.

The oil tankers under construction in the world amount to 22 vessels of 149,064 tons, of which 5 vessels of 31,026 tons are being built in Great Britain and Ireland, 7 vessels of 47,600 tons in Sweden, 2 of 21,726 tons in Italy, 5 of 18,212 tons in Spain, and 1 of 12,400 tons in Germany. Of the 303,762 tons under construction in Great Britain and Ireland at the end of September, 87,294 tons consisted of motorships, while at the same date the motorship tonnage being constructed abroad—about 326,801 tons—was 202,947 tons in excess of that of the steamers. The vessels being built in the world at the end of September include 1 steamer and 11 motorships of between 8000 and 10,000 tons each ; 3 motorships of between 10,000 and 20,000 tons ; and 2 steamers and no motorships of 20,000 tons and upwards.

The table respecting marine engines shows that the horse-power of steam engines now being built or being fitted on board amounts to about 522,000 H.P.; these figures include 22 sets of turbine engines of about 423,000 shaft horse-power. The horse-power of the steam reciprocating engines—about 99,000 H.P.—amounts to 9·7 per cent. of the total horse-power of marine engines now being built in the world. The figures for oil engines aggregate approximately 494,000 H.P.

Although influenced by the reduced amount of shipbuilding in hand throughout the world, the total of the tonnage being built under the inspection of Lloyd's Register at the end of September amounts to 522,046 tons, viz., 275,362 tons under construction in Great Britain and Ireland, and 246,684 tons abroad.

* * *

Ahmedabad municipality proposes to have its own electricity undertaking, which has induced the Ahmedabad Electricity Company to offer the municipality the inducement of tariff reductions in order that the company's supply may continue. The company asks a guarantee of consumption ; on the other hand, it seems the municipality talks of calculations showing that the supply it has in mind will give much cheaper costs. There has been a conference between representatives of both sides, but so far we gather nothing definite has been decided.

---

† M. H. Mawhinney, *Iron Age*, December 17th, 1931.

Motor Car Show at Olympia.

No. II.

(Concluded from page 352, October 13th.)

IT is obvious from a visit to Olympia that finality has by no means been reached in the design of spring suspension systems. The problem is apparently engaging more attention on the part of British car designers than hitherto. Both the Alvis and the Sunbeam companies have something new in this connection, although there are points of similarity common to both. In the new four-cylinder Sunbeam "Dawn" car a transverse front-leaf spring carries the entire weight of the front of the vehicle. As the spring is secured direct to the chassis frame at the centre the vertical movement of each front wheel is controlled by one half of the spring independently of the other half. Swivel brackets, equivalent to the ends of the usual axle, are further controlled by radius rods, which ensure that the angle of the wheel to the ground and the point of contact at various degrees of deflection of the spring are correct. The spring is relieved of the torsional effects of braking, &c., by the provision of long torque rods on either side of the chassis frame. All the joints in the complete mechanism have rubber silent-bloc bushes, which assist in damping the front springing and simplify maintenance, as they do not require lubrication. The four-cylinder engine—Fig. 3—rated at 12·8 horse-power, has cylinders 2·83in. bore by 3·93in. stroke. The engine has a combined cylinder block and crank case of aluminium, the cylinders being fitted with wear-resisting "wet" liners of chrome-nickel iron. Duralumin tappet rods are used to balance the expansion of the cylinder block. Pistons with aluminium alloy heads and steel skirt are fitted, and the mounting of the complete power unit is on rubber cushioning. The car is fitted with the Wilson pre-selective gear-box.

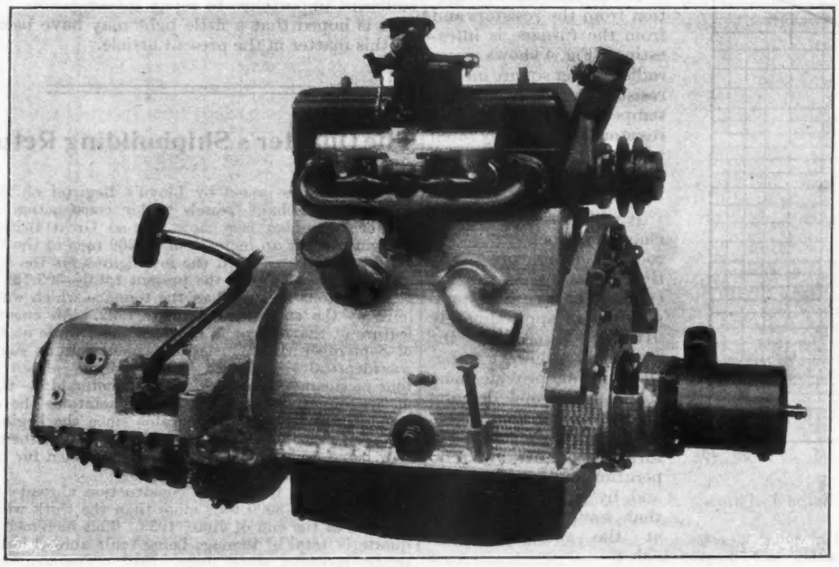

FIG. 3—FOUR-CYLINDER 12·8 H.P. ENGINE—SUNBEAM

Improvements in details of engines include accessible and replaceable oil filters, air cleaners, induction silencers, and downdraught carburetters, with some form of auxiliary starting device for giving a better "pick-up" or acceleration. The fuel feed is generally by some form of positive pump driven off the engine. The Humber Company is introducing quite a number of automatic refinements in connection with the power units. For instance, the ordinary hand strangler, which is liable to abuse by inexperienced drivers, is replaced by a device by which the strength of the mixture of air and petrol vapour is regulated automatically as the engine warms up. Another improvement has been introduced by which the radiator shutters are closed quickly when the engine is stopped. This is not done by the usual thermostat, which is also fitted, but is effected by the engine pressure lubrication system. To prevent excessive cylinder wear it is now a fairly common practice to introduce a special lubricant along with the mixture of petrol vapour and air. The Rolls-Royce Company obtains this effect by automatically admitting a lubricant direct to the cylinder walls only when the starter carburetter is used; that is, when the lubricant is chiefly required. The synchro-mesh gear-box fitted by Rolls-Royce has also an easy change mechanism applied to the second, third, and top gears. The compression ratio of the 40–50 H.P. engine has been increased, giving more power for a given area and a semi-expanding carburetter is introduced.

The Alvis Company is usually to the fore in original ideas, and this year it is showing new features in a 20 horse-power car. Perhaps the most striking feature is the method of spring suspension of the front of the car to give independent springing to each wheel, as in the case of the Sunbeam car mentioned above. This is done by the use of a laminated half-elliptic spring attached crosswise above a rigid transverse member at the front of the frame. Each end of the spring is attached by a shackle bolt to a steel bracket which forms the fulcrum point for the steering pivot. At the bottom of this bracket another shackle pin attaches it to a triangular radius member, the base of the triangle being attached to the frame by a swivel in which is a shock absorber. The deflection of the spring causes the steering pivot and stub axle to rise and fall in a vertical plane. The location of the steering pivot is secured partly by the spring and partly by the triangular radius member. The steering of each wheel is also independent. From each steering pivot a drag link runs to a bell-crank on the frame and the two bell-cranks are coupled together by a track rod, which is also carried on the frame and is coupled up to the Marles-Weller steering gear. The Alvis car has a four-speed gear-box, in which all the gears are of the synchro-mesh type. Helical toothed wheels are used for constant-mesh third and second speeds and straight-tooth wheels for the low gear and reverse. Lubrication of the gear-box is by means of an oscillating plunger pump which forces oil under pressure through the length of the shaft to the gear wheels and bearings.

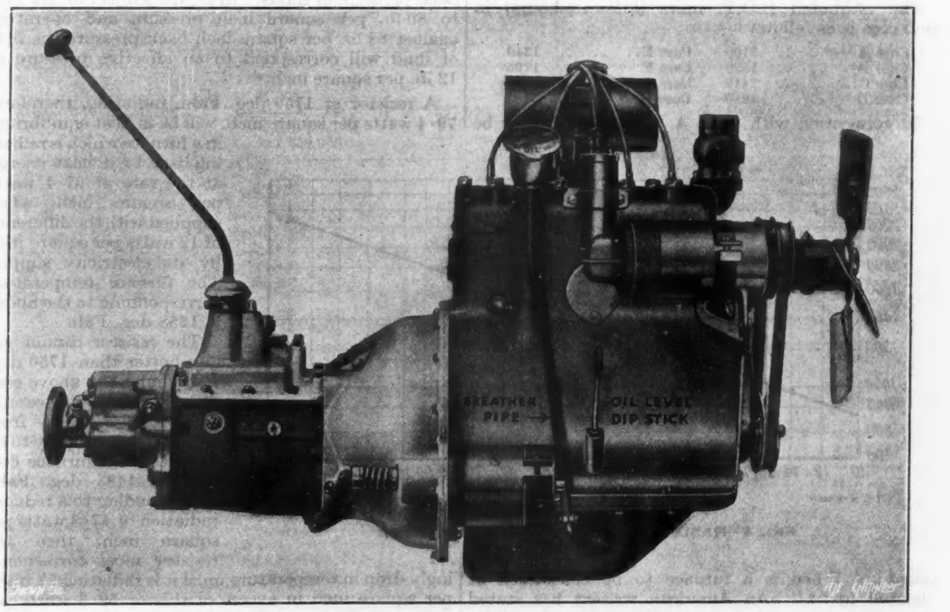

FIG. 4—10 H.P. ENGINE AND GEAR BOX—STANDARD

STANDARD.

The Standard Company's range of cars embodies many important changes in design, not the least of which is the adoption of synchro-mesh gears on the second, third, and top speeds with a controlled free-wheel device. This gives more silent and faster changes of gear. Other new features include the Startix automatic re-starting device in the engine, compensated voltage control of the dynamo, and on the larger cars a four-wheel jacking system. The chassis frame is reinforced by cross bracing. The 9, 10, and 12 horse-power cars are all fitted with improved four-cylinder engines with side valves, aluminium pistons and machined combustion chambers and ports. The engines are all mounted on rubber cushions. A feature which should not be passed over without mention is an accessible oil filler and dip stick for the gear-box. Views of the 10 horse-power engine and gear-box assembly and free-wheel mechanism are given in Figs. 4 and 5.

WOLSELEY.

The Wolseley 1934 programme includes a new 9 H.P. car with an overhead cam shaft four-cylinder engine, gear-box with synchro-mesh top and third speeds, and Pedomatic starting, enabling the engine to be started by the depression of the accelerator pedal. The Hornet models have six-cylinder engines, free wheel transmission, synchro-mesh gears, an underslung double frame and Startix automatic starter mechanism. The 16 horse-power car transmission system now incorporates a free wheel and a vacuum operated clutch which can be put in or out of action as desired. The engine has centre-seal pistons and centri-cast cylinder liners.

DAIMLER AND LANCHESTER.

Fluid fly-wheel transmission combined with the Wilson self-changing gear-box form the main feature of the Daimler and Lanchester exhibits. The 15 H.P. and 20 H.P. Daimler cars have overhead valve engines, while the 25 H.P. and 40 H.P. cars have sleeve valve engines, the latter having twelve cylinders. The associated Lanchester firm confines its energies to 10 and 18 horse-power vehicles, with overhead valve engines having four and six cylinders respectively. They embody the fluid fly-wheel and Wilson gear-box. The B.S.A. company is concentrating on the 10 H.P. car, which has a four-cylinder side valve engine and transmission of the same type as that employed by the Daimler and Lanchester firms. We are informed that over 9000 cars have now been fitted with the fluid fly-wheel transmission system.

RILEY.

Some of the Riley cars, both 9 H.P. and 14 H.P., are fitted with preselector gears and the Newton automatic clutch, which is controlled by centrifugal force. The arrangement is such that the drive is not taken up until a certain engine speed is attained, this being in the neighbourhood of 500 revolutions per minute. In practice the result is that by releasing the accelerator and momentarily depressing the clutch a free-wheel action is obtained. If this is not desired, the engine retains its retarding effect until the car is almost at a standstill. A new type of chassis frame of box section is now used on the 9 H.P. cars.

AUSTIN.

The Austin Motor Company has a wide range of cars from the popular 7 H.P. upwards. The 7 H.P. and 10 H.P. cars have four cylinders, but those rated at 12 H.P. have either four or six cylinders, all with synchro-mesh transmission. One of the chief attractions of the Show is the model of the Hayes "self-selector" transmission system which can be fitted on the 16 H.P. Austin cars as an extra. This is an automatic friction drive device, which makes driving as simple as can possibly be wished. The Hayes gear, Fig. 6, is claimed to be infinitely variable and fully self-acting. The actual transmission is through steel rollers, which transfer the drive between curved steel races, the gear ratio being altered by rocking the rollers to different positions of contact. There are no gear wheels, except for reversing the motion of the car, and the drive is silent. The variation in ratio from 4 to 1 to an overgear 1 to 1·7 is greater than is provided in the normal transmission systems employing toothed gears. On down gradients the overgear is equivalent to a free wheel, but without the disadvantage of disengagement of the engine, and the full braking effect of the engine is available by operating a simple control lever. The driving rollers referred to above are rocked by hydraulic means and finger tip controls enable the driver to vary the running of the car, either to give exceptional performance or utmost economy. Subject to the control setting, the automatic operation of this ingenious gear ensures a constant engine speed whatever the tractive resistance met with on the road, the transmission varying its ratio to balance the resistance as this increases or decreases. In this manner, with the control suitably set for automatc operation, the driver has only to operate the accelerator. The sectional view shows the clutch shaft 1 from which the drive is taken through the dogs to the driving shaft 2 and the two outer races 3 and 4. The rollers 5, of which there are two sets of three, are mounted in a fixed assembly 6, and by rotating transfer the drive to the centre race 7, and thence through the drum 8 to the propeller shaft. The rocking of the rollers to give varying ratios, due to different contact diameters on the driving and driven members, is initiated by the control sleeve 12. Spring washers 9 and the balls between the torque ring 10 and the outer race 3, which wedge in inclined grooves, provide the pressure on the assembly necessary for the transmission of the drive. With this automatic transmission, when starting it is merely necessary to push a lever forward, let in the clutch and press the accelerator, when the car gains speed. By taking the foot off the accelerator the effect is similar to that of lowering the gear ratio, and *vice versâ*.

Morris.

The range of Morris cars for 1934 includes the 8 H.P. Morris Minor, 10 H.P. four-cylinder, 11·9 H.P. four-cylinder, 12 H.P. four-cylinder, 15 H.P. six-cylinder, 16 H.P. six-cylinder, and 18 and 25 H.P. six-cylinder cars. All of these have four-speed synchro-mesh gear-boxes in unit construction with the engines, giving an easy change of speed on the third and top. From the 10 horse-power car upwards new stiffened frames are provided with cruciform bracing. The four-cylinder Morris 10 H.P. car makes a strong appeal to users of "moderate means." It is a coach-built saloon with sliding head. The engine has a capacity of 1292 c.cm., and has a detachable head with air cleaner, preheater, and fume consumer. The engine has forced lubrication to the main bearings and side valves, coil ignition with automatic advance, finger-tip controls for ignition, driving, &c. The brakes are hydraulically operated and the steering is by cam. Armstrong hydraulic shock-absorbers are fitted to the suspension system.

Accessories and Components.

In many respects the accessories and components section of the Exhibition is more attractive than the car section. The exhibitors in this section comprise the makers of the many individual parts upon which the operation of the cars depends, such as carburetters, ignition devices, engine details, and lubrication equipment. In this department the Triplex Safety Glass Company, Ltd., shows a new kind of toughened glass which, when broken, crumbles into small fragments. This glass does not become discoloured with long usage in hot countries, nor does it blister as is the case with some makes of laminated glass. Within limits it can be twisted and bent without fracture, and it will withstand heavy blows. The A.C.-Sphinx Sparking Plug Company, Ltd., Birmingham, has an attractive display, including plugs of various kinds, oil filters, petrol pumps, air cleaners, gauges and speedometers. The necessity for clean air in the fuel mixture is being increasingly recognised if cylinder wear is to be minimised, and the A.C. Company makes centrifugal and oil-wetted cleaners. In the former the air is made to revolve by means of fixed blades, and the particles of dust are ejected through a slot in the body of the cleaner. In the oil-wetted type the air passes through woven metallic mesh soaked in oil, which retains the dust particles. There is a third type which combines an intake silencer and air cleaner in which, by the use of harmonic principles, secondary sound waves are set up within the silencer to nullify the intake roar. This device has to be designed and tuned to suit each individual induction system, and is therefore a fitment for the car manufacturers rather than for adoption by the users.

Simms Motor Units, Ltd., Gresse-street, Rathbone-place, W.1, shows a range of new atomisers and fuel injection pumps for compression-ignition engines which have several original features. In the atomisers there are three outstanding features—a detachable nozzle cap, a protected needle guide, and a screw-operated ball relief valve to expel the air from the fuel pipe system. The fuel pump operates on the "jerk" system, in which an accurately metered quantity of fuel oil is introduced into the pump chamber before the commencement of the working stroke. By cam action the plunger is thrust upwards, thus discharging the contained oil through a delivery valve, delivery pipe, and atomiser into the engine combustion chamber.

In the service and garage section of the Show, Tangyes, Ltd., Birmingham, have a stand on which are exhibited a hydraulic car lift, a range of air compressors with a special centrifugal unloading device, car-washing pumps, oil engine generating sets and greasing outfits.

Examples of modern chain-driven systems in operation are shown by the Renold and Coventry Chain Company, Ltd. Interesting features of this firm's exhibits are the methods of adjustment of the chains, of which there are three types, designed to give quiet running and long life of the chain. The designs consist of self-contained units complete with fixing means, chain wheels and bearings, and it is necessary only to provide for suitable fixing bosses adjacent to the chain drive for holding the auto-adjuster bases. The principle of operation is to urge forward by gentle spring pressure the chain wheel in contact with the chain. A ratchet device prevents the return of the chain wheel and all danger of overstraining the chain due to heat expansion is eliminated by the design of the ratchet mechanism, which includes a sufficient margin of "lost motion" after operation.

Technical Museums.*

By H. W. DICKINSON.

The earliest conception of a technical museum, and at the same time the first breakaway from the seventeenth century idea, so far as I have been able to find, emanated from the brain of that celebrated philosopher Francis Bacon, Viscount St. Albans (1561–1626). His "New Atlantis," written in 1625, left unfinished and not published till 1627, gives an account of an imaginary commonwealth or "Utopia." A former king of the Island Atlantis had founded an order or society known as Salamon's House. One of its Fellows favoured Bacon with an account of it: "Sonne, to make you know the true state of Salamon's House, I will keepe this order. First I will set forth unto you the End of our Foundation. Secondly, the Preparations and Instruments we have for our Workes. Thirdly the severall Employments and Functions whereto our Fellowes are assigned. And fourthly, the Ordinances and Rites which we observe."

I will only quote part of the "fourthly," although the whole is worth reading. "For our Ordinances and Rites: Wee have two very long and Faire Galleries: In one of these we place Patterns and Samples of all manner of the more Rare and Excellent: Inventions: In the other wee place the Statua's of all Principall Inventours. There wee have the Statua of your Columbus, that discovered the West Indies: Also the Inventour of Shipps; Your Monke that was the Inventor of Ordnance, and of Gunpowder; The Inventour of Musick; The Inventour of Letters: The Inventour of Printing: The Inventour of Observations of Astronomy; The Inventour of Works in Mettall: The Inventour of Glasse: The Inventour of Silke of the Worme: The Inventour of Wine: The Inventour of Corne and Bread: The Inventour of Sugars; And all these, by more certaine Tradition, than you have. Then have we diverse Inventours of our Own of Excellent Workes: Which since you have not seene, it were too long to make Descriptions of them; And besides, in the right Vnderstanding of those Descriptions, you might easily erre. For upon every Invention of Valew, wee erect a Statua to the Inventour, and give him a Liberall and Honourable Reward. These Statua's are some of Brasse: some of Marble and Touchstone; some of Cedar and other speciall Woods, guilt and adorned; some of Iron; some of Silver; some of Gold."

It will be observed that Bacon's idea was to have a museum of inventions and a portrait gallery of inventors; they were to be in long galleries—quite a modern touch—and as much space was to be devoted to commemorating the "Principall Inventours" as to illustrating their "Rare and Excellent Inventions." The "Atlantis" is only an airy fantasy, but we shall find later how Bacon's ideas were reduced to practice.

An early suggestion for a museum of a technical character occurs in a letter from Samuel Hartlib to Robert Boyle in 1649: "Fauxhall is to be sett apart for publick uses, by which is meant making it a place of resort for artists, mechanicks &c and a depot for models and philosophicall apparatus," adding that the late King (*i.e.*, Charles I.) "designed Fauxhall for such an use." It had recently been a small arms factory. Nothing, however, came of the suggestion.

René Descartes (1596–1659) in France made a similar suggestion of collections for the instruction of artisans. Perhaps the earliest collection of mechanical apparatus was the cabinet of Nicholas Grollier de Serviere, of Lyons (1596–1689). I do not know what happened to this cabinet.

My attention has been drawn by Mr. Gomme to a rare book, "Explication des Modeles des Machines et forces mouvantes que l'on expose à Paris dans la rue de la Harpe vis-a-vis Saint Cosime," 1683, 4to, in which are described and illustrated twelve models apparently in a public museum; other models are stated to be in preparation. Nothing whatever is known of the origin or fate of this experiment; I can only suggest that it was before its time.

In the eighteenth century the growth of trade and industry brought about the formation of technical societies, of which we need only mention as typical the Society for the Encouragement of Arts, Manufactures and Commerce, founded in 1754. Its purpose was to award premiums for meritorious discoveries and inventions. Till

---

* From the Presidential Address, Newcomen Society for the Study of the History of Engineering and Technology Oct. 11, 1933.

1845 it was a condition of the premium that the article should not have been patented. The Society's first exhibition—of agricultural and other machines—probably the earliest industrial exhibition anywhere, was held in 1761. Thereafter the Society kept up a permanent "Repository" of machines that had been premiated, available to the public by an order from a member. The collection was weeded out from time to time, but when the Society began to hold temporary exhibitions and space was needed the models had to go; we shall record their fate later. As a guide to search, it is worth mentioning that a "Description of the . . . Machines . . . in the Repository" was published in 1772 by William Bailey. A classified catalogue appeared in 1814.

Patent Office Museums.

We have now to consider another aspect, that of the registration of technical advance by means of models of patented inventions and for this we have to turn to the United States. The first enactment of a patent law by Congress was in 1790, and both in this and in the Act of 1793 the Secretary of State, if he thought fit, could call upon the patentee to deposit a model of his invention—really to serve as an amplification of the specification. A classified list published in 1823 shows that there were then 1819 models in existence. They increased rapidly, but, to the number of about 7000, were swept away with all other records in the disastrous fire on December 15th, 1836; much was done to replace them in the succeeding decade. As time went on patentees reduced their models to minimum requirements, with the vast increase of patents the demands upon space became enormous, and the opinion hardened that they were not really necessary. Hence the law of 1870 did not require a model to be furnished, but still many were made. In 1891 there were 154,000 in existence; since then the practice has been discontinued altogether.

Parallel with the development in the United States, one of another character was going on in France, brought about by that outburst of the human spirit, the French Revolution. Influenced possibly by the Encyclopædists, the idea was broached of founding a technical museum coupled with a teaching body of wide scope. The decree of the 19 Vendemière an III (October 10th, 1794) recites: "Art. ler.—Il sera formé à Paris sous le nom de Conservatoire des Arts et Métiers et sous l'inspection de la Commission d'agriculture et des arts, un depôt public de machines, modèles, outils, dessins, descriptions et livres de tous les genres d'art et métiers; l'original des instruments et machines inventés et perfectionnés sera deposé au Conservatoire.

"Art. 2me.—On y expliquera la construction et l'emploi des outils et machines, utiles aux arts et métiers."

The Conservatoire started with two valuable nuclei. One was the collection of machines formed by Jacques de Vaucanson (1709–1782), the well-known mechanician, and thrown open by him to the public in 1775. At his death he bequeathed his machines to King Louis XVI. The other nucleus was the apparatus collected during the first century of its existence by the Académie Royal des Sciences. These objects had only been known up to that time through the publication of "Machines Approuvées," 1735, six volumes, which is such a mine of information to us to-day.

After much deliberation as to the future home of the Conservatoire, the Directory ordered that the buildings of the sequestered Priory of St. Martin-des-Champs, then used as a small arms factory, should be allocated for the collection. Thither they were removed in April, 1799, and there they have remained to this day. It was not till 1819 that full effect was given to Article 2me of its constitution by the inauguration of courses of public lectures, a feature that has been considerably extended since. Testing laboratories, too, have been added.

To return to England, we find in the early part of the nineteenth century great public interest being taken in the mechanic arts, due to influences which are too well known to need recapitulation. By the middle of the century the advance in ideas that I have mentioned above came about, *i.e.*, that a museum should have as its aim the advancement of specific knowledge. I have not traced this idea to any particular individual, and possibly it arose gradually by an extension of the idea underlying teaching and reference collections accumulated in colleges and universities, such as the Hunterian Museum (1795) of the Royal College of Surgeons in London.

Impetus was given to the idea by the Great Exhibition of All Nations of 1851. A surplus resulted from it, and this, under the directing advice of H.R.H. Prince Albert, was devoted as one outlet to the foundation in 1857 of the South Kensington Museum. Its aim was to promote the application of art and industry and to illustrate the progress and development of science. Obviously, a new attitude towards the kind of object admissible to such a museum had to be adopted. Nothing is eligible that is not justified as part of a considered scheme.

Parenthetically, it may be observed that the name museum, associated as it still is in the public mind with the seventeenth century concept, quite fails to cover this development; in spite of all efforts, however, no better name has been found.

Bennet Woodcroft.

I must now introduce you to a man whom I consider in a sense one of the founders of this Society—Bennet Woodcroft (1803–1877), F.R.S., himself an inventor, Professor of Machinery at University College, London. To him in that capacity the bulk of the models from the Society of Arts Repository had been presented. He had occupied the post for four years when he was appointed Superintendent of Specifications, an office created under the Patent Law Amendment Act of 1851. He entered upon his duties in December, 1852, and at once displayed great zeal and energy in rendering available to inventors the materials relating to inventions in the custody of the Master of the Rolls. In particular, he succeeded in inducing the Commissioners to print the Letters Patent for inventions, with specifications when such were enrolled, from 1617 onwards. We have therefore him to thank for making available a corpus of information of the utmost value to our historical studies. It will interest members to know that the pre-1617 patents have been similarly taken in hand by some of our members, and it is profoundly to be hoped that, when completed, funds will be made available for their publication.

Woodcroft brought with him to the office his library of books and his collection of mechanical models. The first formed the nucleus of the Patent Office Library, and the second that of the Patent Museum. We are concerned only with the latter. I have not come across a public statement of its aims, but they were obviously based on Bacon's fantasy, with which Woodcroft was familiar. In short, he determined to make Bacon concrete. His diary shows that he had the approbation of H.R.H. Prince Albert, and it was probably through his influence that Woodcroft got permission from the 1851 Commissioners to house his collection in the buildings of the South Kensington Museum, opened in 1857. Woodcroft objected to the charge of 6d. on students' days, and Sir Henry Cole, the Director, would not yield, so that the Patent Museum was housed from 1857 to 1883 in unsightly iron buildings, irreverently known as the "Brompton boilers."

Woodcroft was well qualified for his post, and knew what he wanted. He soon began searches for masterpieces of invention, and made efforts to recover objects known to have been in existence, such as Lombe's silk-throwing machines, patented in 1718, examples of which were deposited in the Tower of London by Act of Parliament in 1741. He was successful in recovering some fragments.

One of his boldest attempts was to recover the Marquis of Worcester's "water commanding engine." Woodcroft circulated (1860) to all likely departments and persons a lithographed appeal, but without success. Now in "The Century of Inventions," Art. 98, the Marquis said of it: "I call this A Semi omnipotent Engine and do intend a Model thereof to be buried with me." Consequently, Woodcroft concluded that the thing to do was to open the Marquis' coffin, which was in the family vault in Raglan Church, Monmouthshire. Having obtained after much trouble the permission of the ecclesiastical authorities and of the family, he, accompanied by John Macgregor (1825–1892), barrister of the Inner Temple, best known subsequently as "Rob Roy," on January 4th, 1861, visited the church, opened the vault and the coffin, but found no model there. A full account, with sketches of this gruesome search, is preserved in the Science Museum and at the Patent Office Library. I will only quote one sentence from this unique document: "Out of respect to the remains of the mighty dead, we did not open the cloth over the face, but were satisfied that there was no model buried in that part of the coffin." Woodcroft's intention had leaked out, and to his annoyance comments had appeared in the Press in the June and July previous, but the actual deed was done in secrecy, and to this day is only known to a few persons.

In other quests Woodcroft was more successful, and through his exertions we owe the preservation of Watt's first pumping engine, "Old Bess," 1777; Watt's rotative engine, the "Lap engine," 1788; Arkwright's cotton machinery, 1769–1780; Symington's marine engine, 1788; Bell's "Comet" marine engine, 1812; "Puffing Billy," 1812, and the "Rocket" 1829, locomotives; Bell's reaping machine, 1826; and many other objects of less importance, but all of them documents of the highest value to us, and not approached anywhere else in the world. At that time such objects were not appreciated, and more than one of them was actually on the scrap heap, so that but for Woodcroft it is certain that these would have been for ever lost. It ought to be mentioned that he had an able lieutenant in the person of Sir Francis Pettit Smith (1808–1874), nicknamed "Screw Smith," from his introduction of the screw propeller, who was Curator of the Museum.

One word about the Gallery of Inventors—it sounded a desirable human note, and led to research in the biographical field, which had it been longer delayed would have resulted in much being lost. The Woodcroft Collection of such information is preserved fortunately in the Patent Office Library, and deserves to be better known. Woodcroft retired at last in 1876 and died in 1879. No adequate biography of him has appeared, and it is to be hoped that some member will take up the task, ample material for which exists at the Patent Office Library.

A cloud now settled over the Patent Museum. It was suggested that it should be abolished, and, in fact, this is what happened, for under the Patent Designs and Trade Marks Act of 1883, it was transferred during the succeeding two years to the South Kensington Museum. Here, however, it was in no happier state, for science was then the Cinderella of the piece and art received all the plums. However, brighter days dawned in 1890 when my first chief and staunch friend, William Isaac Last (1857–1911), Wh.Sc., was appointed Keeper of the hybrid-entitled Division "Machinery and Inventions." I date from this appointment the dawn of the third period in museum technique that I have mentioned, that of making a museum a living institution by such arrangements that the whole public can be made to understand what they see and derive educational advantage from a visit, arrangements contemptuously stigmatised by superior persons as "making the wheels go round."

SIXTY YEARS AGO.

One of the world's forgotten benefactors is the man who invented the decimal point in arithmetic. Very few people, it may here be remarked, seem to be aware that it is not the same thing as the full point(.) which we put at the end of our sentences nor the full point turned upside down (·), but a special symbol (·) all by itself, higher than the one and lower than the other. This typographical discrimination is not always observed, but the fact that it exists may be taken as a mark of the importance and dignity which we should attach to the decimal point. It is certainly worthy of all the respect which we can give it. It is much more than merely a separator dividing integers from fractions. A mere comma might equally well have served that purpose. Actually, it implies that the figure immediately following it is to be read as so many tenths, the second figure as so many hundredths, and so on. It is so simple and obvious to-day that it is almost impossible to believe that the use of the decimal point did not come automatically into use as soon as man began to express fractions in terms of tenths, hundredths, and so forth. Yet it did not do so. Like many another great invention, it passed through early complex stages before it reached its final simplicity. Decimal arithmetic is commonly believed to have been invented by Simon Stevin, of Bruges, round about 1585. His system of notation was, however, just about as cumbersome as it well could have been. He wrote the number 18·2468—pronounced "eighteen point two four six eight"—as 18 (0) 2 (1) 4 (2) 6 (3) 8 (4), but used complete circles where we have used parentheses—and pronounced it as "eighteen commencements two primes four seconds six thirds and eight fourths." The numbers in brackets indicated the exponents of one-tenth which were to be used to form the multiplier of the unbracketed numbers preceding them. This idea persisted for a long time in a variety of forms, a common one being $18, 2^{I}4^{II}6^{III}8^{IV}$. It took a genius to see that the exponents were quite unnecessary, and that the mere position of any number in the sequence following the decimal point was sufficient completely to specify the understood exponential value. Briggs, the inventor of common logarithms, seems to have been one of the earliest to break away from the use of exponents explicitly inserted in a decimal arithmetical expression. All his life he used a notation in which the decimal portion of the expression was underlined thus: $18\ \underline{2468}$. Oughtred avoided the ambiguity which might be introduced by careless underlining by using the notation $18\,/\,\underline{2468}$. But, even so, they were forestalled in simplicity by Napier, the inventor of natural logarithms. It was Napier who introduced the decimal point as we know and use it to-day, although it was many years before it came into extensive employment. Actually in neither of the works which he published in his lifetime—the "Mirifici logarithmorum Canonis descriptio," of 1614, and the "Rabdologia," of 1617—did he use the decimal point. It was in the "Mirifici logarithmorum Canonis constructio," published under the editorship of his son in 1619, two years after his death, that he defined the decimal point and made use of it in all respects similarly to the modern method of employment. As the history of mathematical notation is a subject prolific of controversy—witness the international tension produced by Newton's and Leibnitz's quarrel concerning the notation of the calculus—we wish to make it clear that the statements in this note are made on the responsibility of a paper read before the British Association in 1873 by Mr. J. W. L. Glaisher, and reprinted in our issue of October 24th of that year.

TREVITHICK CENTENARY.

The Trevithick Centenary Commemoration Committee has now in hand or promised sufficient funds to enable it to carry out in a modest way the purposes which it it had in view when it was constituted last October. These aims are a Memorial of Trevithick's London locomotive of 1808, in London; a Monument on the line of track of his South Wales locomotive, 1803, at Penydaren; and a Tablet at his birthplace, 1771, in Illogan Parish, Cornwall. All these are now in preparation. The London Memorial is to be erected within the precincts of University College, by permission of the Committee of the College. The site has been chosen because it was near there that the locomotive Catch-Me-Who-Can was exhibited on a circular track. The publication of the Memorial Volume has been ensured by the kindness of a well-known firm of engineers; the work is now in the press, and will be published, it is hoped, in December.

OBITUARY.

SINCLAIR PEARN.

Mr. Sinclair Pearn, whose death occurred suddenly at his home in Manchester on October 10th, in his eighty-fifth year, was, together with his younger brother Frank—who died some years ago—instrumental in founding the engineering firm of Frank Pearn and Co., Ltd., Gorton. Mr. Pearn was a wonderfully active man for his years, and attended at the works as recently as the day preceding his death. He was particularly concerned with the commercial side of the business, and was keenly interested in costing systems, on which subject he wrote a book entitled "Workshop Costs for Engineers and Manufacturers," in 1905. The firm's reputation as pump makers is world-wide, and the design of the horizontal boring and facing machine, now built by two other firms, originated at Messrs. Pearn's works. Mr. Pearn was a very keen amateur gardener, and by his association with a well-known organisation in Manchester was largely instrumental in raising large sums of money for charitable causes.

To appreciate the point made by Lieut.-Colonel Anderson, in his report on the Raynes Park accident of May 25th, as to the time-interval between trains being considered, when lifting a road, as well as the height of the lift, it should be said that the only rule specifically referring to lifting the track is No. 224. That rule, moreover, only says that no lift must be greater than 3in. at once. Then, in Rule 217 (*g*), lifting is named as one of the works that may call for a speed of 15 m.p.h., or such other reduced speed as may be prescribed, and for such work a flagman must be stationed to secure the reduced speed. No intimation is given in the latter rule as to what degree of work would make it necessary for the train to travel at reduced speed, whilst Rule 224 appears to imply that a lift of 3in. or less is safe. There was also the matter of time between trains. In this case it was ten minutes, and by the time the train approached three or four lifts had been made of the rail in question, but the last lift could not be completed, and some sleepers were quite unsupported.

Railway and Road Matters.

The London Passenger Transport Arbitration Tribunal has entered into occupation of its offices at Columbia House, Aldwych, W.C.2 (telephone number, Holborn 7305). Mr. Paul C. Davie, Barrister-at-Law, is Secretary.

After two days' trial at Carlisle Assizes, the porter-signalman charged with manslaughter as a consequence of the Little Salkeld accident of July 10th, was acquitted on October 11th. It was given in evidence that the man was still in the service of the railway company.

During the railway strike in Ireland last February a Great Northern express was derailed at Dromiskin, and two people killed. The railway company made a claim for £15,000 against the Louth County Council, which came before the Dundalk Circuit Court on October 11th, when judgment was given for £7450.

The through service between the former Metropolitan District Railway, also the Piccadilly tube, and Uxbridge, which is on what was the Metropolitan, to which we referred on September 15th, will be opened on October 23rd. The two companies' lines terminated in South Harrow Station, where a change of trains used to be necessary.

Representatives of the railway companies and of the three railway unions met on Tuesday, the 17th, to discuss some new conciliation machinery to take the place of the National Wages Board. It will be remembered that, at the beginning of the year, the railway companies gave twelve months' notice of their intention to retire from the present scheme.

The Ministry of Transport railway statistics for June also gave the results for the first six months of the year. These show that, compared with the corresponding period of 1932, the number of passenger journeys increased by 0·4 per cent., but the receipts therefrom fell by 0·8 per cent., and the total passenger traffic receipts by 1·0 per cent. The tonnage of freight had a drop of 3·7 per cent. and the freight traffic receipts were down by 5·6 per cent, Of these two figures, merchandise was reduced by 5·2 and 5·8 per cent. respectively. Freight train-miles were reduced by 2·8 per cent.; the average train load fell from 121¼ to 120¼, and the net ton-miles per engine-hour from 446¾ to 445¼.

The collision of June 17th, between a Leeds and Bristol express and a mineral train, which was referred to herein on October 13th, has generally been referred to as the Ambergate collision. We have, however, preferred to give it the name of the signal-box—Crich Junction—at which it occurred. We have done that out of compliment to George Stephenson, who, when building the North Midland Railway, got his Liverpool friends to establish the well-known Clay Cross Collieries and to build lime kilns at Ambergate. The limestone quarries are at Crich, and the stone was conveyed—and it is still—by an inclined plane 3 miles long. At the foot of the incline is the Cromford Canal, to which reference was made on page 361 of our issue of October 13th. It was at Tapton House, Chesterfield, some 15 miles from Crich, that Stephenson died.

Mention was made in the Press recently of the extensions being made by the Wandsworth and District Gas Company at its works at Wandsworth. These works are of interest to railway students as being the scene of the commencement of the Surrey Iron Railway, the first railway opened for the conveyance of the traffic of the public, and not alone that of certain individuals, *e.g.*, colliery owners, canal companies, &c. The line was sanctioned in 1801, and was from a dock or basin in Wandsworth Creek at or near a place called the Ram Field. The creek in question is where the river Wandle enters the Thames, and is now the property of the above-named company. In The Engineer of January 5th, 1900, was an article on the Surrey Iron Railway, and the lock gates, a crane, and some other items of the original work were illustrated.

It was seventy years, on October 1st, since the Great Northern trains began to run over the Metropolitan Railway from King's Cross to Farringdon-street by means of a junction with what is now the Inner Circle line. On February 17th, 1868, the two lines outside the Inner Circle, always known as the widened lines, were brought into use and the junction with the Great Northern was then transferred to the widened lines. To complete this particular point in railway history, it may be added that on July 13th, 1868, the Midland Railway opened its Bedford and London extension throughout for passenger traffic. Part of that extension was a connection from near Camden-road Station to the Metropolitan at King's Cross at, practically, the junction with the Great Northern. As the Midland terminus at St. Pancras was not ready to receive traffic, the trains ran over the Metropolitan to and from Moorgate.

The death recently of Sir George Beaumont, of Cole Orton Hall, Ashby-de-la-Zouch, prompts a reference to two of his ancestors. At the end of the sixteenth century, one, Huntingdon Beaumont, was sent by his father, Nicholas Beaumont, who was said to be the then largest coal-owner in Leicestershire, to Germany. Thence, according to William Gray's *Chorographia* (1649), he brought back "many rare engines not known in these parts, such as . . . waggons with one horse to carry down coals from the pits to the staithes on the river." Huntingdon Beaumont was concerned with others in the development of coalfields near Bedlington, in Northumberland. He was spoken of as "of Bilborough, near Nottingham." That place is near Wollaton Hall, the seat of the Middleton family, whose papers were recorded by the Historical Manuscript Commission in 1911. References therein suggest that there was a wagon way from the pits at Wollaton and in the adjoining locality of Strelley to the river Trent as far back as 1597. This implies that Huntingdon Beaumont introduced the wagon-way—the forerunner of the railway—into this country from Germany towards the end of the sixteenth century. The head of the Beaumont family in the earlier years of the nineteenth century was Sir George, of whom Abraham Rees' "Encyclopædia" (1819) said that he was "the owner of the collieries at Cole Orton, to which railways have previously been made at great expense connecting the Leicester Navigation."

Notes and Memoranda.

At the new Buzzard Point power station of the Potomac Electric Power Company the lubricating plant for the turbines is arranged in an underground fireproof chamber, and the pressure pipes are run inside welded return drain lines.

In an article on ingot slicing tools in the *Edgar Allen News*, Mr. B. H. Chambers describes some of the difficulties associated with the tipping of such tools with alloy steels. He says, however, that a technique has been evolved such that the bond between the tip and the shank is so close that the toolroom has occasionally failed to recognise that the tip had been entirely used up, and time was wasted in the machine shop in attempting to use the worn-out tools. The schooling of the grinders in the relative appearance of the sparks from the tip and the shank has, however, eliminated this drawback.

A process for the production of an artificial patina on copper has been evolved by the research laboratories of the Department of Scientific and Industrial Research. It is apparently an electrolytic process and is said to produce an effect in fifteen minutes that would require twenty years of natural exposure to create. The best results are obtained with arsenical copper, containing some ½ per cent. of arsenic, the presence of arsenic securing a better bond between the deposit and the underlying metal. Arsenical copper is also definitely more resistant to atmospheric corrosion, and an accumulation of arsenic has been shown to take place in the natural product. It is significant that, of the old copper roofs of which analyses are possible, all are arsenical.

Writing to *Power*, Mr. J. S. Carpenter, of York, Pa., says :—A small hydro-electric plant had trouble with eels getting into the racks and turbine casing, eventually clogging up the casing entirely and necessitating shut-downs for unsavory cleanings. Various measures were tried to remedy the condition, such as closer spacing of rack bars, without satisfactory results. Then someone suggested making the rack bars alive, believing this would discourage entrance of the eels. The individual bars were then insulated from each other and 55-volt alternating current connected across them. This corrected the trouble. At another plant, a cofferdam frame was built with 1in. heavy wire mesh screen confining 8in. of 1·5in. crushed stone between the two sides of the cofferdam. This gave fair results, only a few eels getting through.

Discussing the filtration of drinking water supplies in the *Engineering and Contract Record*, Mr. N. J. Howard, of Toronto, says that the introduction of artificial turbidity promises to be a feature in the future. It is well known that water high in plankton life is usually free from turbidity; in fact, microscopic organisms will not thrive in water containing finely divided silt, and the introduction of turbidity into a reservoir water at Louisville some years ago was shown to reduce rapidly the micro-organisms. Again, it has been frequently shown that water will not coagulate well if the number of organisms present is large. There is also a probability that during warm weather certain colloidal properties in water are in some way associated with poor flocculation. Mr. Howard suggests activated carbon or Fuller's earth as the means of increasing the turbidity.

The annual report of the Water Department of Singapore, Straits Settlements, contains a reference to some experiments made with a 12ft. length of 4in. internal diameter armoured rubber pipe connected to the town's water supply and immersed in the sea. Service conditions involved an internal working pressure of about 45 lb. per square inch. The rubber pipe was first immersed on December 24th, 1930, and when last inspected on October 18th, 1932, was found to be in excellent condition. It was then tested to 100 lb. per square inch without any sign of leakage or failure. The supply pipe connecting this length of rubber pipe with the rest of the distribution system has frequently failed through the corrosive action of the sea water. Various types of metal connecting pipes have been experimented with, but none of them has survived the conditions mentioned for more than four months.

Air turbines have been applied during recent years to the driving of grinding spindles, and have proved to be very convenient and reliable. They are, says Mr. J. F. Romer in *Machinery*, of such simple construction that if the principles of design were better known they would doubtless be put to many other uses. Where very high speeds and perfect balance combined with cool running are required, air turbines are superior to electric motors. They could be used, for example, to drive individual cotton-spinning spindles instead of the high-frequency electric motors commonly employed, with very little difference in efficiency and considerable reduction in the amount of heat generated; they could also be utilised in conjunction with ground gears to drive suds pumps, cream separators, and sugar centrifugals. As they can be made almost entirely of aluminium alloys, their light weight makes them ideal for portable tools.

In his Melchett Lecture to the Institute of Fuel, Sir John Cadman said :—"It has been stated, I believe with a measure of accuracy, that the production of 1 lb. of motor spirit necessitates the hydrogenation of 1·6 lb. of coal. In addition, however, coal or other fuel is consumed in the operation amounting, in relation to 1 lb. of spirit produced, to 1·6 lb. of coal. The process of hydrogenation, moreover, needs hydrogen for its accomplishment, and it may reasonably be assumed that hydrogen representing a thermal value of 8300 B.Th.U. is needed for every pound of petrol produced. In all, therefore, 48,300 B.Th.U. in coal or other fuel and hydrogen are consumed in the synthetic production of 1 lb. of motor spirit which, when it is attained, has itself a net calorific value of 18,900 B.Th.U. per pound. The ratio of potential energy consumed to that produced is, therefore approximately 2·5 to 1; or a thermal efficiency for the process of 39 per cent. And the object achieved—unlike that obtained by gasification—is the production merely of a substance which at the present time Nature itself is yielding in plethoric quantity. To judge by scientific standards, such a transformation is unnecessary and wasteful.

Miscellanea.

It has been decided to construct a dam and six power units on the Columbia River at Bonneville, Oregon, at a cost of 31,000,000 dollars.

It is proposed to put up a benzole recovery plant at the works of the Dublin Gas Company. It is intended that the benzole shall be used by the company's motor vehicles.

The new regulations under which the duty paid on fuel oil used on board coasting steamers and during trial trips may be recovered, can be obtained from H.M. Stationery Office, price 2d.

The pumping equipment of the City of Montreal has just been augmented by the addition of three 30,000,000 gallons a day centrifugal pumps, each driven by a 1900 H.P. motor taking three-phase current at 2300 volts.

The magnesite mines in the Vidourre Valley, near Salinelles, in the Department of Gard, Southern France, which have not been worked for fifty years, are again being exploited. The ore is to be used in the French mineral-oil refineries for the purification and clarification of petroleum.

It is claimed that the cargo of the s.s. "Cressington Court," which is just now being unloaded in the London Docks, is the largest cargo of soft wood ever brought into the port. She carries 2500 standards (a standard is 165 cubic feet) of Douglas fir, brought from New Westminster, British Columbia.

Notice is given that the Croydon Corporation has applied for the consent of the Minister of Transport to supply to the Southern Railway Company electricity to be used for any purposes of the railway undertaking. Notice is further given that the railway company have also applied for the consent of the Minister to use the electricity so supplied.

A second meridian of the Canadian Dominion Lands system of survey has been surveyed northerly from the international boundary to the north bank of Kamuchawie Lake in township 85, a distance of over 500 miles. This lake, which lies across the Manitoba-Saskatchewan provincial boundary, and the northern terminus of the surveyed meridian are shown on the Reindeer Lake South map sheet recently issued by the Topographical Survey, Department of the Interior, Ottawa.

It has been decided, says the *Canadian Engineer*, to proceed with the construction of five large generators at once for the Beauharnois power development. It was originally expected that these generators would not be required until about 1937, but the Canadian General Electric Company, Ltd., has decided to proceed with the contract now at its Peterborough works. These five generators are duplicates of four machines already installed. Each generator will have a capacity of 58,000 horse-power and will weigh 650 tons. They will have an outside diameter of 40ft. and an overall height of 28ft.

The Government of the Belgian Congo has, according to the *Daily Telegraph*, decided to use on a wide scale the Harris tsetse fly trap, which has been invented by Mr. Harris, entomologist to the Government of the Union of South Africa. Successful experiments have been carried out with the trap, and it is hoped that it will prove the means of controlling the deadliest scourge of the African Continent—the purely tropical disease of sleeping sickness. At the invitation of its Government, Mr. Harris has just spent three months experimenting in the Belgian Congo. He has so reduced the number of flies there that they now attack only wild animals. The trap had previously been proved harmful only to the fly carrying cattle disease.

The Official Returns rendered to the Electricity Commissioners show that 1023 million units of electricity were generated by authorised undertakers in Great Britain during the month of September, 1933, as compared with the revised figure of 923 million units in the corresponding month of 1932, representing an increase of 100 million units, or 10·8 per cent. The number of working days in the month (*i.e.*, excluding Sundays) was twenty-six, the same as last year. During the first nine months of 1933 up to the end of September the total amount of electricity generated by authorised undertakers was 9352 million units, as compared with the revised figure of 8641 million units for the corresponding period of 1932, representing an increase of 711 million units, or 8·2 per cent.

It is announced by the Plastics Group of the Society of Chemical Industry that, in view of the great and continued interest which has been shown in the Plastics Industrial Exhibition at the Science Museum, South Kensington, the display will remain open until January 15th, 1934. During the six months the Exhibition has been open no less than three-quarters of a million people have visited the Science Museum, and it is reasonable to suppose that the great majority of them have been attracted to Gallery 66, where the main display of plastics is housed. It is felt that a permanent record of the Exhibition in the form of a handbook dealing generally with all the exhibits will meet with the approval of both those in the industry and the general public. The Society of Chemical Industry hopes to be able in due course to publish such a handbook and a further announcement will be made later.

The iron ore which has just started to come into this country from Sierra Leone, and is thus an Empire product, is of similar type to that of the iron ore fields of India. It is anticipated that the average analysis of the ore will be 57 per cent. of iron in a dry state. It contains 0·04 per cent. of phosphorus, and is suited for the manufacture of foundry and basic pig iron. The deposits will be worked by open-cast quarrying. The loading installation was supplied by the Mitchell Conveyor and Transporter Company, Ltd., of London; the railway has been equipped with powerful "Garratt" locomotives by Beyer, Peacock and Co., Ltd., of Manchester; and the wagons were supplied by the Metropolitan-Cammell Carriage, Wagon and Finance Company, Ltd. All plant, machinery, tools, and stores used in the construction of the railway and the loading installation and in the equipment of the mine are of British origin and were shipped to Sierra Leone in British steamers.

THE USE OF FLYING.

WE discussed a few weeks ago Sir Josiah Stamp's challenging address to the British Association at its Leicester meeting. In the course of his survey of the problem he had set himself, whether scientific advance must ever prove a stumbling-block to economic progress, he did not have much to say about the results of the invention of flying, though he did suggest a doubt whether the debit side of the account has not got a good deal ahead of the credit. The same doubt was expressed by Lord Trenchard, when Chief of the Air Staff many years ago, in bluntly stating—an alarming suggestion at first sight—that if he had his own way he would "abolish the air." In view of these statements, it is useful to see how the "air" entry in the ledger really stands. Many people, including, it seems, Sir Josiah Stamp, at once put all armaments on the debit side; this is hardly fair, but it is in a sense natural, for what it really means is that the technique of attack is at present much more facile than the technique of defence. But, even so, it does ignore the generally admitted, and undoubtedly real, economy both in life and treasure of using the air arm for police purposes in undeveloped countries, especially when these are difficult of access by surface routes.

However that may be, let us see what can, with confidence, be set to the credit side. The first item which everyone would enter is civil air transportation. Here is a fairly comfortable, and not too risky means of very rapid travel, which is of especial value when the surface conditions are interrupted by river, sea, or lake. For long journeys over land in competition with railways, the advantages are less marked, and until night flying becomes common they are likely so to remain. But for a type of journey, such as that from London to Paris, the air route is the pleasanter to most people, as well as being much more rapid. With civil air transport must be included, of course, the air mail services. Almost equally well known, though less developed, is air survey. Few people realise how many supposedly civilised countries are most inadequately surveyed. There is great room for development here, and the air method is well worth support, whether for topographical or cadastral purposes. The taking of stereoscopic photographs from the air enables contours to be plotted, and as an indication of the accuracy attainable, the Air Survey Committee of the War Office has published such a contoured map printed on transparent paper and having the Ordnance Survey for the same area printed on the other side; comparison of the two is most comforting to both methods. It is not suggested that either the one or the other must necessarily be the best method to adopt, each must be judged in relation to the accessibility of the country and the estimated cost of the work. But we may here point out that the air method is still young, and that great advances have recently been made in both speed and accuracy by the use of gyroscopic control for stabilising the surveying aircraft and its camera. For the survey of the lake country of Canada the air method is unrivalled. For forestry surveys and for archæological exploration it is equally good, and it is being seriously used for mining surveys. For military surveys in time of war it is essential, but as that use relates to armament, one must presumably put it down on the other side of the ledger. Canadian experience has also shown the use of the aeroplane for fire patrol and even for fire fighting—a form of fighting which does go down on the credit side, as must also American and Russian experience on crop dusting with insecticide. Mining is not only assisted by aeroplanes used for survey, but by actual transportation of mining machinery. The mines in the heart of New Guinea are so dependent on aircraft that not merely is all the *personnel* so carried, but the heavy machinery itself, despite its weight of many tons. The most recent development is the use of aeroplanes to combat the terrible scourge of locusts. Here is an attack on a real air enemy, which fortunately, if it succeeds, will go down among the greatest of assets. Locusts, when in the hopper stage—that is, before they have grown their wings—are customarily attacked on the ground by the use of poison bait. There are other ways, but that is the best. Damp molasses and sawdust, with a sprinkling of arsenic, is, oddly enough, a mixture enjoyed by locusts, but the meal is fatal; the succeeding ranks of the moving host feed on the poisoned bodies of their fellows, and so the good work goes on. But sometimes the terrain is unsuited to this method, and always countless millions escape the attack and grow to flying estate. To deal with these has so far proved an insoluble problem, but the experiment of attacking them from the air is now to be undertaken. The staff work is in the hands of the Locust Control Committee of the Economic Advisory Council, and preparations are well on the way. A very finely divided poison dust will be used, and it will be scattered in so thin a cloud as to avoid the risk of danger to ground dwellers. But, thin as the cloud is, it appears from laboratory experiments made on batches of locusts flown home from East Africa by Imperial Airways, and on some bred for the purpose in this country, that the enemy is conveniently sensitive to it. Death is expected to ensue to any locust which flies through this cloud. All that has to be done, therefore, is to lay a suitable cloud trail across and ahead of an approaching swarm. It was first intended to carry out the test among the huge swarms infesting Kenya, but whether because the plan became known to the locusts or for some other reason—the right one has not been ascertained—practically all the swarms committed mass suicide before the experiment could begin! So it will have to start in the regions further south among the "red locusts," which, it is to be hoped, will prove less temperamental than their "tropical migratory" brethren of Kenya.

The issue, in every sense of this latest experiment, is still "in the air," but great hopes are being built on it. If it succeeds, it may well indicate a means of saving millions of pounds' worth of crops in ensuing years. The idea is a fascinating one, as it opens up the alluring prospect of a kind of three-dimensional disinfection against plagues and diseases of many sorts. Surface transport operates in two dimensions, air transport in three, and the consequences of that additional freedom have yet to be fully worked out. When they are we may all be greatly comforted by benefits to the human race which will amply merit entry on the right side of the ledger.

Professional Ethics.

THE address which Mr. A. C. Dean delivered on Wednesday, October 11th, to the Manchester and District Association of the Institution of Civil Engineers, as chairman of the Association, drew attention to some matters in connection with the professional conduct of consulting engineers which are of more than local interest. His remarks afford an opportunity for comment on that code of professional ethics, written and unwritten, which is supposed to govern the relations of consultants to their clients and to their fellow-members of the engineering profession. It is with the comparatively limited number of those who practise as consulting engineers, using that term in the sense generally understood in this country, that Mr. Dean is concerned, and not with the "host of non-professional engineers with high-sounding titles, appendages, and pretensions" which has grown up in recent years. He recalled that "a few years ago an American paper collected some 300 titles by which these pseudo-engineers had described themselves in that country, among whom were such unusual branches of our profession as publicity engineers, income engineers, clothes engineers (obviously entitled to the old appendage 'C.E.'), completing the list with 'the exterminating engineer.'" Almost every professional society provides in some form a code of conduct for the guidance of its members, such codes in general being chiefly for the purpose of determining rules of professional practice, the observance of which should tend to the maintenance of amicable relations between its members and just dealing between them and contractors and clients. The by-laws of the Institution of Civil Engineers contain, as Mr. Dean pointed out, rules laid down for professional conduct which are perhaps purposely limited to cover only relations with the public. There is nothing in these by-laws which directly governs the general conduct of the civil engineer towards his colleagues. The rules of professional conduct of the Association of Consulting Engineers, which are designed for the guidance of those whose work is of a purely consultative character, go much further than the by-laws of the Institution and form a sound code of ethics and useful rules of professional practice. Mr. Dean quoted the words of Dr. Tudsbery, on the occasion of the meeting in 1918, commemorating the founding of the Institution of Civil Engineers, in reference to the rules of the Institution as to professional conduct. Their general purport, said the then secretary of the Institution, "is to ensure that the engineer's utmost skill shall be placed at the disposal of those who employ him, and that the method of his remuneration shall not involve any conflict between his personal interests and those of the client whom he advises." This, Mr. Dean observed, may be paraphrased "as 'seeing that the client gets his money's worth,' and it is not enough. The fiercer competition of recent years may have tended actually to make many of the purely ethical rules honoured more in the breach than in the observance, but the principles of honesty and fair dealing should be within the conscience of every man."

Important matters of actual practice discussed by Mr. Dean in his address are those of the relations between architects and engineers, and between engineers or architects and designing firms of a commercial character. Modern building methods make the joint operations of engineer and architect imperative, and there must often be overlapping in their respective spheres of work to such an extent as to make it almost impossible to draw the line between their responsibilities. A difficulty which has occurred from time to time in this respect has been in regard to the allocation of fees. The mutual relations of architects and engineers in these matters should be capable of adjustment, and we believe that negotiations between representatives of the two professions with this object have been and still are in progress. But another difficulty of even greater importance has arisen in recent years. A client arranges a fee with his engineer or architect, and it is therefore only human nature that the engineer or the architect, who is not usually lavishly rewarded for his work, whatever it may be, should want to get as much of the fees available as is legitimately and ethically possible. The practice has therefore sprung up of obtaining the apparently gratuitous assistance of specialist designing or manufacturing firms in providing designs for the engineer or architect in cases where he is not competent to do the work himself. Of course, such services are not in any true sense gratuitous, and the cost of them is in many cases met in some manner that is not overt to the clients. In such cases the effect is that the client pays twice for his engineering or architectural services, and the matter therefore may be one of unprofessional conduct. The Ministry of Health has in recent years done something to minimise this undoubted abuse in the case of public works and building operations carried out by local authorities under its control. Another matter which bristles with difficulties, and on which professional opinion is much divided, is that of the permissible limits of advertisement, direct or indirect, in the case of consulting engineers. It was, said Mr. Dean, "an essential requirement of the old code of conduct that the client should seek the engineer while the latter remained quietly waiting in his office. We know perfectly well that this is rarely the case in fact. It is illegitimate in theory for consulting engineers to compete in any way for work, but if they are to obtain engagements they must achieve the same result by indirect methods. It is frequently the case that the only measure available to this end is some form or other of self-laudation." Too frequently an engineer struggles to bring his name before the public, principally through the medium of the Press, in various ways which are considered legitimate; and it must be said that to the unprejudiced onlooker these operations occasionally appear somewhat ridiculous. It is, said Mr. Dean, "inevitable that the engineer must practise some form of advertisement and come out into the market to sell his wares in the form of his technical skill. There are far more professional engineers than there used to be, while the public has no means, unless through occasional personal knowledge, of knowing . . . what engineers are available to help them, and what are their experience and ability." As he sees it, there is to-day, for good or ill, a tendency for the profession of engineering to move more and more towards a purely commercial basis, and the profession of architecture is probably developing on similar lines. The young architect is able to bring his name before the public through the medium of competitions, but this is not usually a course open to the engineer. A growing practice, which has nothing to commend it and combines self-advertisement with the transference of professional labour and duty from the person who ought to be responsible to another party whose payment is frequently indirect, "is the practice whereby an engineer or architect employed by a public authority or commercial undertaking claims credit as the designer of a particular structure, whereas in actual fact the whole scheme has been worked out by competitive commercial interests who, directly or indirectly, have received remuneration for their work. Such an engineer or architect usually 'gets away with it' by stating that the details were prepared by Messrs. ———." In Mr. Dean's view this is "cheap and unworthy even if the present elastic limits of professional rules are not actually exceeded." It has often been suggested, in the course of the last few years, that corporate advertising on behalf of and controlled by some professional engineering body might be advantageous to consulting engineers generally, and would avoid all the objectionable features which are inherent in personal advertisement, direct or indirect. Mr. Dean, in his address, said that "corporate advertising on a very modest scale has already been carried out by some professional bodies, and it must be admitted that it is very doubtful whether the public in general has been affected one way or the other."

It is not too much to say that Mr. Dean's address crystallises ideas and aspirations which have been present in the minds of many consulting engineers for some time past. There are obvious difficulties which confront the Council of the Institution of Civil Engineers, and, to a lesser extent, the governing bodies of the other great professional institutions, in extending rules of professional conduct and in enforcing such rules in practice. The Association of Consulting Engineers has done something in this direction, and its influence is not confined only to the members of the Association, but extends over a wider field. Nevertheless, the present conditions cannot be regarded as satisfactory. The Institution of Civil Engineers and the other institutions seem to be powerless to deal with abuses in practice which, we fear, are increasing both in magnitude and in variety. One suggestion which, in our opinion, is well worth consideration as a means whereby the control of the professional conduct of consulting engineers could be strengthened and extended, is that the Institution of Civil Engineers should enlarge the functions and strengthen the powers of its professional conduct committee to enable the latter to co-operate in furthering the work now being done by the Association of Consulting Engineers. Alternatively, it might be possible to delegate to the existing Engineering Joint Council the powers possessed by its constituent institutions of formulating rules of professional conduct, and the duty of advising the councils of the respective institutions in matters of discipline relating to those of their members who are engaged in consulting practice. Neither of these suggestions was made by Mr. Dean in the course of his address, but it seems to us that one or other of them offers, at any rate, a possible and practicable method of dealing with the unsatisfactory and somewhat chaotic condition of affairs, as, for instance, in regard to the vexed system of advertising, which now exists in the profession.

Fuel and Man.[*]

By Sir WILLIAM J. LARKE, K.B.E.

[The address opens with a very attractive survey of the history of fuels and their use by man, and continues as follows.]

We are now in a position to take a general survey of the enormous increase in the utilisation of mechanical energy which has resulted from the progressive developments which have been all too briefly sketched. It is calculated that the average man requires, for the maintenance of his physical well-being, between 3000 and 4000 calories per day—less than one-tenth of a therm, or, say, about 25 therms per annum. Since the thermal efficiency of the human body cannot be assumed to be greater than 25 per cent., we can imagine the limitations under which mankind constructed some of the great structures of ancient times, requiring as they did the expenditure of considerable physical energy to place the materials in position.

The increase in productivity and control of the resources of Nature, with which the mechanical extension of his powers has provided man, cannot be better expressed than by an approximate estimate of the heat and power consumption (reduced to therms), per head of population, of the principal industrial countries. The six countries having the highest total heat energy consumption, including coal, oil, and water power, are given in the following table :—

Consumption per Head of Population in 1929 (*Therms*).

Country.	Population, millions.	Coal.	Petroleum.	Water.	Total.
Canada	9·00	1406	252	75	1733
U.S.A.	106·00	1006	515	10	1531
Belgium and Luxemburg	7·87	1465	20	—	1485
United Kingdom	44·50	1196	46	—	1242
Germany..	63·00	1216	18	2	1236
France	40·00	699	31	5	735

The heat energy per head of population, it will be noted, varies from 2 therms per head per day in France to 4½ therms per head per day in Canada—say from 30 to 70 times as much as before the mechanical era.

The wide discrepancy in heat consumption per head in different countries is of considerable interest, particularly as the six countries in question enjoy a very similar, and indeed practically equal, standard of material culture and in the widest sense of industrial development.

In Canada the high consumption is no doubt largely due to the severe winter and the consequent high consumption of fuel for domestic purposes, and also to the very high proportion of fuel per head of the population utilised for transport purposes, owing to the long distances separating the different communities, which necessitate a very extensive railway system, there being nearly 50,000 miles of railway for a population of 9,000,000 people. In the United States, which has the next highest consumption per head, this is doubtless due to the highly developed railway system, the high domestic fuel consumption in the Northern States, and the high density of motor cars to population as indicated by the particularly high oil consumption. With regard to the development of the motor car, it will be noted that the consumption of oil is twice as high in the United States as in Canada, which has the next highest consumption. Although this disparity is not entirely due to the motor car, it is no doubt the dominant factor.

In Belgium the relatively high consumption per head, even as compared with the United Kingdom, is due to the highly industrialised character of the country, and the consequent large proportion of the population engaged in fuel-consuming industries. The United Kingdom and Germany are more or less directly comparable in conditions and fuel consumption. In France, the relatively low consumption is due to the fact that France is still mainly an agricultural country, in spite of the very highly developed industrial areas of Lorraine and the northern provinces.

The maximum industrial development of the future may be expected from those countries which, while having large agricultural areas, also enjoy considerable natural resources of potential mechanical power in the form of coal, oil, or water. Not only do such resources permit the growth of local industries to meet the needs of their own population, but they provide the means of development of transport of the agricultural produce of the country throughout a widely scattered community, and, in countries like Canada, which produce an annual surplus of such produce, a means of exporting it to industrial countries which are not self-supporting in foodstuffs.

Although water power as a source of energy is of very great importance in certain countries where natural conditions favour its development, as in Canada, and in certain parts of India, it is not an important factor at present in relation to the world production of power. In 1932 water power was only responsible for some 3 per cent. of the total world power production. Oil was responsible for 19 per cent., and coal and lignite for the balance—some 78 per cent.

It is true to say, therefore, that "Coal is still King." It must be admitted that oil has been used with great success under present world conditions for steam raising and the production of mechanical energy by direct combustion, even in competition with coal. Nevertheless, despite the substantial inroads that it has made into some markets previously served by coal, it seems unlikely ever to replace coal or its derivatives as the important fuel on which our modern civilisation is based.

In June, 1933, according to Lloyd's Register of Shipping, out of 66,500,000 tons of mechanically propelled shipping in the world, 56,500,000 tons was steam and 10,000,000 tons oil. It would seem that the development of the modern turbine, high steam pressures and superheat will give a definite advantage to steam so long as oil must be used in engines of the reciprocating type. While this does not preclude the use of oil instead of coal for steam raising on such ships, this would be a question of the relative availability of oil and coal, particularly as regards price. This would be largely conditioned by the demand for oil and its derivatives in internal combustion engines on the one hand, and the cost of transport and refuelling stations on the other.

The advantages of oil firing for boilers are undoubtedly great, but principally of a character where they will find their greatest advantage in warships and liners, leaving the greater proportion of the steam-propelled tonnage of the world to use coal, with possibly equal advantage to oil, all things considered. Such a general statement is obviously open to controversy, but it is probably sufficiently accurate to indicate the general trend of coal consumption for marine purposes in the near future.

From 1905 to 1930 the world production of coal and lignite increased from 900,000,000 tons to approximately 1,400,000,000 tons, whereas oil production during the same period increased from 27,000,000 tons to nearly 200,000,000 tons. Thus, the rate of increase in oil, as would be expected from the development of the internal combustion engine both in motor cars and for power purposes, is very much greater during that period. It must be borne in mind that up to recent times coal or its derivatives could not have provided an alternative fuel for the motor car in its present form, so that this consumption is not provided from oil at the expense of coal, whatever may be the case in the future as a result of the development of the hydrogenation of coal, the use of pulverised coal, and particularly the use of compressed gas.

A new development from America is the introduction of butane, which can be compressed to a liquid form at a comparatively high temperature. This is finding a large market for the provision of heat and light in isolated districts. The boiling point of butane at atmospheric pressure is 14 deg. Cent., and it has a very high calorific value. This, however, is at present derived from natural gas, and is therefore dependent on the continued availability of supplies. Experience obtained from this development may result in the use of compressed gas more extensively in the future than in the past, particularly if the economic availability of oil products in relation to coal and its derivatives were to undergo any change that would increase their value.

Efficiency.

What is the effect on fuel industries of increasing efficiency in their utilisation? Since nearly all fuels are at present natural products that cannot be reproduced synthetically from other products, they must be considered as a wasting asset. As early as 1563 a law was passed in Scotland prohibiting the export of coal, as it was thought that the mines were being exhausted too rapidly. The discovery of new resources continually puts forward the probable date of exhaustion, in spite of increasing demand. While this may be true of the world, or even of a country, there are districts and localities in which exhaustion may well have important and serious consequences, involving the transfer of population in the comparatively near future. New centres of population are naturally growing up round the newly developed coalfields and centres of industry, the availability of fuel being the most important factor in this distribution.

---

[*] From the Presidential Address to the Institute of Fuel, October 18th, 1933.

In the development of a mechanical age, if there is no conscious effort at conserving wasting assets, such as coal and oil, there is the incentive to economy in their use resulting from the ever-increasing pressure of competition to reduce the cost of industrial products and services. The effect of this increasing economy on the rate of increasing consumption is well brought out in the recent interesting report issued by H.M. Chief Inspector of Mines.

In this report it is pointed out that while the make of gas between 1913 and 1931 has increased in the United Kingdom by nearly 40 per cent., the amount of coal carbonised has only increased by 7 per cent. In the case of the generation of electric power, while the increase in units generated since 1921 is 165 per cent., the amount of coal consumed has only increased by 37 per cent. One of the largest coal-consuming industries is the iron and steel industry, and although the quantity consumed is affected by the depression through which this industry has been passing, it has also been reduced to a considerable extent by the increase in fuel efficiency in that industry, as the coal consumption per ton of pig iron in 1932 was only 36·4 cwt., compared with 40·14 cwt. in 1913.

An important factor in this increase in efficiency, in coal consumption in particular, is the close study of the properties of the different qualities of coal available in the United Kingdom, and the application of the vast amount of knowledge which has been accumulated by the Coal Survey of the United Kingdom. The work of the Fuel Research Board, Imperial Chemical Industries at Billingham, the gas companies and their research organisations, both individual and collective, in the laboratory and by large-scale experiment, have transformed coal in the last twenty years from a raw mineral fuel used wastefully in the raw state, to a source of multifarious invaluable chemical products, providing, in addition, a variety of fuels having much wider application than coal in the raw state, and thus increasing its general availability and, in time, its consumption. It may not be generally realised that there are many hundreds of different varieties of coal, if qualities and sizes are treated as separate varieties, as they should be. Market research in determining the best quality and size for a particular service must also result in increased efficiency in the use of fuel.

There is no doubt that the work of such bodies as the Coal Utilisation Council must ultimately result in giving to the community the maximum service per unit of price, and securing to the coal industry the maximum price per unit of product. This result is being attained by the introduction in the coal industry of methods of mechanical and chemical treatment that can almost be described as manufacturing processes. The actual winning of the coal is only one, if the most important, of the many operations to which it is subjected before it is utilised as fuel. These processes increase the range of service for any particular quality of coal, and thus increase the value of natural resources to the community possessing them. These operations are so varied that in some cases they are actually conducted as separate industries. As apart from sizing, cleaning, and crushing, there is the production of coke with its by-products, which themselves enter into an entirely different range and sphere of consumption; and last, but by no means least, in scientific interest is hydrogenation.

The large-scale research in hydrogenation of coal being undertaken by Imperial Chemical Industries, Ltd., will provide a source of oil fuels for use in a national emergency, even if it does not ultimately prove possible to compete on equal terms with the natural product. But of even greater importance is the development of a technique of large-scale hydrogenation generally applicable to other products which may well have incalculable results in the future.

It is only through a *planned* technological economy that industrial progress under present conditions can be secured. The fuel industries are more fortunate and perhaps more advanced than most industries in having an accurate statistical basis for their production and distribution policy. It is of first importance to the community that industry generally should be conducted on a profitable basis, for an unprofitable industry is detrimental to the well-being of the community in which it is situated.

It is not sufficiently recognised as one of the difficulties of industrial recovery in the post-war period that industrial development such as has been so inadequately traced in this address has concentrated on the volume and efficiency of production on the assumption that distribution would continue to take care of itself. While this was ceasing to be true at the beginning of the present century, the dislocation of credit, and consequently of purchasing power, resulting from the financial problems of the war, in addition to those created by the setting up of new frontiers and new states, each inspired by a natural but intense economic nationalism tending towards self-sufficiency, has produced a condition where production is in excess of the immediate demand.

Science and industry must play their part in studying more intensively the problems of distribution. It may be fairly claimed that the problems of production, on which such a large proportion of scientific, technological, and industrial energy and intellect have been concentrated for the past 150 years, have been solved, though progress must be continuous in the future. Perhaps the greatest incitement to those whose sphere of work lies in the realm of science, technology and industry, is that no sooner is a problem solved or an obstacle passed than the horizon widens, showing still further possibilities with their problems awaiting solution. But in the absence of a revolution comparable to that which was produced by the introduction of steam and mechanical power, the rate of production, even in the distant future, is likely to be slower, if for no other reason than that its utility will be less until the problem of distribution has been solved. It is on this aspect of our modern problems that the best minds must concentrate their attention. It will no longer be sufficient for the scientist and the technologist to announce discoveries, but with the knowledge they possess of the potentialities of such discoveries they will also require to study the application of their achievements to the welfare of mankind.

It is frequently stated that it would appear as if the development of the mechanical era had produced more problems than it had solved, and that man has eaten of the fruit of the tree of knowledge to an extent that will compass his own destruction. Such a view is, I think, unwarranted, in spite of the evidence to the contrary in the abuse of the developments of science and technology during the war years in their application to the destruction of life and material. The mechanical extension of mankind, in producing with reduced effort ever-increasing wealth, has had the effect, to a greater or less extent, almost throughout the population of the world, of raising the standard of life as compared with the standard existing before the Industrial Revolution in the middle of the eighteenth century. What is needed is surely that man shall rather increase his consumption of the fruit of the tree of knowledge, in that he shall learn how to use to better advantage the wealth and power he has learnt to produce.

OIL IN THE WORLD OF FUEL.

On Wednesday evening, October 11th, Sir John Cadman, the Melchett Medallist, lectured to the Institute of Fuel and other technical societies on "The Place of Oil in the World of Fuel." The President of the Institute of Fuel, Sir Hugo Hirst, was in the chair. After a short reference to the easy transport of oil as compared with coal, the lecturer stated that the most striking rivalry between fuel oil and coal was to be found at sea. A large proportion of the world's ocean-going shipping was now propelled by oil. In 1914 statistics of the tonnage of the world's mechanically propelled shipping showed that 96·6 per cent. used coal and 3·4 per cent. oil. To-day the figures were respectively 54·6 per cent. and 45·4 per cent. The latest available figures indicated that motor ships now afloat had a tonnage of over 10,000,000 and represented 15 per cent. of the world's shipping. Oil had, he said, not replaced coal indiscriminately, but had been adopted for those purposes to which it was particularly suited. Sir John rejected the view that oil was solely a competitor of coal and that the advent of oil and the development of oil-consuming mechanisms had brought no advantages to coal. Virtually every part of every motor vehicle constructed in this country represented a consumption of coal. Similarly, the aeroplane had made its demand upon coal; a compression-ignition engine for use abroad was an export of the energy of coal; a farm tractor was a substitution of coal for horses; a motor boat was an additional factor in the demand for coal. The world's annual production of coal was, Sir John pointed out, vastly greater than that of oil, and amounted in 1932 to over 1000 million tons, and the maritime consumption of oil, less than 20 million tons, was small in relation to the world's annual output of coal, and could not of itself alone have been the cause of all the misfortunes which had befallen the British coal industry. In conclusion, Sir John reminded his hearers that the world's reserves of fuel—whether oil or coal—were limited, even though their full extent remained yet unknown. It was therefore to our interest, and to that of posterity, that each fuel should be made to yield the maximum amount of energy which human ingenuity could extract from it.

FRENCH COLLIERY PRACTICE.

At the inaugural meeting of the Congress of Industrial Chemistry, recently held at Lille, Monsieur Champy, managing director of the Mines d'Anzin, gave an interesting account of the progress that has been accomplished in the utilisation of coal at the French collieries. In the Nord, the capacity of coke production is 5,200,000 tons, but in 1932 the quantity produced was only 2,731,000 tons. The products of distillation comprised 103,110 tons of tar, 36,063 tons of sulphate of ammonia, and 22,900 tons of benzol, while 540,000,000 cubic metres of gas of about 4200 calories were available for distribution. All the tar is distilled by one company, which is capable of dealing with 130,000 tons a year. Several processes are employed for the production of synthetic ammonia, the quantity last year being 61,937 tons, transformed principally into sulphates, and several collieries have laid down plants for sulphuric and nitric acids. Only one colliery has undertaken the production of ethylic alcohol, which, moreover, is making little headway, owing to the limited demand. Carbonic oxide in coke oven gases is harmful to the catalytic manufacture of ammonia, and it was therefore necessary to combine it first of all with hydrogen for the production of methylic alcohol, which it was hoped would find increasing employment as a motor fuel. Two collieries produced 528,000 gallons of methylic alcohol in 1932, part of which was transformed into 200 tons of "formol." The colliery companies in the Nord do not contemplate the production of oils by the hydrogenation of coal, on account of the enormous capital involved and the necessity of protection against imported oils. More immediate results are anticipated from the hydrogenation of liquid products which has already reached a semi-industrial stage. Rather than attempt the hydrogenation of coal, the companies mining bituminous coals prefer low-temperature carbonisation in order to obtain a more porous coke suitable for domestic heating and a gas of higher heat value, together with a richer tar. Two companies have laid down plants which will produce yearly 200,000 tons of semi-coke, 17,000 tons of tar, 475,000 gallons of spirit, and about 20,000,000 cubic metres of gas of 6000 calories. The development of the chemical side of the colliery industry will depend upon the demand for semi-coke, which is, incidentally, being advocated in France as a substitute for anthracite for domestic heating. The association of industrial chemistry with coal mining is also an outcome of the increasing tendency of colliery companies to develop their power generating stations which are necessary for the utilisation of unsaleable coal, and having thus available a considerable surplus supply of electrical energy, the companies have embarked upon the electro-chemical industry, and in 1932 produced 15,393 tons of calcium carbide, 9481 tons of cyanamide, and 771 tons of electrolytic copper.

Literature.

SHORT NOTICES.

The Principles of Electric Arc Welding, Metallic Arc Processes. By R. C. Stockton. London: Sir Isaac Pitman and Sons, Ltd. Price 7s. 6d.—Although much has been written on electric welding, those who have not yet familiarised themselves with the subject, and perhaps even some who are already engaged on welding work, may welcome this new volume. It is based on lectures delivered by the author at the Manchester College of Technology; but, where considered necessary, additional matter has been introduced. Although the major part of the book is devoted to arc welding, spot, butt, and resistance seam welding are considered. Other matters briefly covered are sherardising, electro-plating, galvanising, white-metalling, cast iron, oxy-acetylene welding, and thermit welding. A section is devoted to the principles of manufacture of iron and steel, and the heat treatment of high iron content alloys is discussed. A lengthy chapter covers arc welding in its various aspects and is followed by another on examples of welding practice in which illustrations of real practical value are to be found. Another equally practical chapter is devoted to the testing of welded work and welding materials. Finally, there is a chapter on electrical notes, which serves to familiarise non-electrical people with welding plant and with electrical terms. Of the many books we have seen on electric welding this is one of the most useful from the point of view of those engaged in workshops.

Advanced Electrical Measurements. By W. R. Smythe and W. C. Michels. London: Chapman and Hall, Ltd., Price 15s.—During their experience as teachers of electrical engineering, physics, and chemistry at the California Institute of Technology, the authors of this volume have been unable to find a text-book containing all the material deemed to be essential for the purpose of training electrical students in the use of electrical measuring instruments, and they have, therefore, produced a book of their own. To keep it within reasonable limits, where there are several alternative methods of measuring or comparing the same quantities, the one which has been found to be most satisfactory is fully considered, whilst the others are only referred to. Standard material to be found in most books on electrical measurements, with, perhaps, rather more than usual emphasis on electrometers and the recent types of amplifying valves, is to be found in the first eight chapters, whilst the remaining four are devoted to the application of electrical methods to the measurement of quantities which are not primarily electrical in nature. Because of their ever-increasing application in physical and engineering laboratories, temperature and radiation measurements are considered in considerable detail, and an endeavour has been made throughout the volume to make instructions sufficiently clear to enable students to become versed in the subject of electrical measurements without the help of an instructor. An effort has also been made, wherever possible, to discuss theory before giving actual experimental directions to enable the student to understand the apparatus he uses.

The Position of British Engineering Industries.[*]

By WILLIAM REAVELL, President, B.E.A.

When I had the honour of addressing you two years ago, at the conclusion of my first year of office as your President, I presented to you some reflections on the great amount of time which had to be devoted by the heads of engineering undertakings to financial and cognate matters which had to be dealt with, and which were quite remote from that kind of engineering which lies nearest to the hearts of most of us, namely, the designing of our different mechanisms so as to obtain the highest efficiency with the greatest economy in weight, the development of our experimental work, and similar matters, so as to keep our products in the forefront in the face of international competition.

The intervening period has been fraught with many difficulties, and it occurred to me that some reflections on these and their bearing on the position as it is viewed to-day by the head of an engineering concern would be acceptable to you.

Two years ago, England had just left the gold standard, and had carried the population with it in the formation of a National Government. Its actions in the two intervening years have, on the whole, interpreted the will of the nation, and although the progress has been slower than many armchair critics would like, because it has been governed so much by circumstances and conditions outside our own country, we have seen considerable changes effected which it is difficult to believe could have been carried out under any system of Party Government.

The confused condition of the world, which, two years ago, we so much deplored, cannot be said to have clarified itself in the intervening period. On the other hand, we find a still more uncertain, and, indeed, threatening, political position in Central Europe, while the circumstances which led to frozen credit in so many countries have not yet found those milder conditions which would exercise a thawing influence for the benefit of those engineers who are still suffering from the lock-up of their capital abroad, or who are desirous of extending their commercial tentacles in those territories. Indeed, in the economic sphere matters have been rendered still more difficult by the action of America, who, on the eve of the World Economic Conference, left the gold standard deliberately, and not by the force of external circumstances, as in the case of our own country. We are all of us watching with intense interest, and, indeed, with some dubiety, the consequent steps which are being taken in that country, with the object of making debts tolerable and industry profitable, regardless of the effect her actions may have on the world outside. To put it bluntly, the United States of America, by that action, probably did more to make the World Economic Conference abortive than any other single circumstance. When the Conference actually met, we, therefore, had the position that France and other gold countries were determined to remain anchored to gold, because of their earlier experience of the consequences of severe inflation, while, on the other hand, America was pursuing a policy of reflation. Probably all of us agree that our own National Government acted wisely in evading the issue between these two methods and deciding not to embrace either of them. It practically meant that those in charge of Great Britain's policy preferred that this country should retain its freedom of action. It does seem, under the present conditions, that a variable pound forms a flexible and automatically adjustable factor in an otherwise rigid system, and has performed a function of the greatest economic value.

In the present unsettled state of affairs, it is very difficult for the ordinary engineer to forecast in any way what the world results will be, but, at all events, we can say that our present financial policy has assisted in what we hope will be the starting of a trade cycle on its upward trend. Our credit in the world remains second to none, and, as a well-known economist happily put it a little while ago, " we remain on the gold standard as regards our character and credit."

The industrial position in our own country seems now to be definitely improving, although, for the reasons referred to, export conditions still remain very difficult and are aggravated by the extreme spirit of economic nationalism, which is so rampant. If, instead of this, we could see the dawning of an era of sane international co-operation, the effect upon world economy would be immediate and emphatic, and the British engineer—who, throughout these troublous times, has never ceased in the development and improvement of his machines—would begin to come into his own again.

Tariffs.

These reflections would not be complete without some reference to the difficult question of tariffs. While we doubtless still agree that the machinery adopted —by means of which our own tariff problems are dealt with by an independent advisory Committee, which can consult with each trade in turn—is wise, we engineers are disposed to deplore recent movements by which trade agreements have been effected with certain foreign countries, apparently without bringing this machinery into full play and without a proper consultation with the trades affected, which undoubtedly include our own engineering trade.

In regard to the importation of certain manufactured articles duty free, one has doubts whether the method at present adopted can have the effect of encouraging British firms to undertake the manufacture of types of machinery not yet made in this country, since they have not the protection which the imposition of a suitable duty would afford.

Let us study the position as it occurs to any one of us who sees the free importation of any machine or apparatus which is in line with the class of machinery he makes, and which he is confident he could satisfactorily produce.

To do so, involves a period of study and investigation, followed by careful design to ensure that the highest efficiency shall be maintained and that it can be produced on the most economical basis. This done, he has now to expend considerable sums in manufacturing the machine in the various sizes required, and in advertising and other ways of making his machines known.

During this period, the machine is being imported duty free, and he must introduce his machine against this price handicap, probably coupled with the fact that the imported machine is made under lower labour conditions than those obtaining here. Even then, until his machine is well known, he cannot hope to be assisted by the imposition of a duty on the imported article.

Is it to be wondered at that under these conditions the British manufacturer hesitates to incur the large financial risk involved ?

Admittedly, if the foreign machine had to pay the duty imposed on that class of machine, the home purchaser would have to pay more for it, but he does so now on other articles which are subject to duty, and if the present principle were altered it would be a great encouragement to our engineering trade to undertake the manufacture of new machines under the protection afforded, and it would also lead to the employment of more skilled and unskilled labour.

I cannot leave this part of the question without pointing out how effective and useful the efforts of the B.E.A. have been in staying the free importation of such machinery in cases where the Association has been able to prove that suitable machines for the purpose could, as a matter of fact, be provided by its members or by other firms, who, though not yet supporting the B.E.A., have benefited directly by its action.

In addition to the question of whether the present tariffs afford adequate protection to British manufacturers, so as to encourage them in further developments which would employ more labour, there is undoubtedly a menace with which it is difficult to deal, even by high tariffs, namely, the flooding of our markets by the productions of certain countries, particularly in the East, who pay extremely low rates for labour. It is sometimes accompanied by definite attempts to evade the mark of " Foreign manufacture," as in a case cited at a recent conference by a representative of the pottery trade, who gave an illustration of the importation of Japanese cups and saucers, sold in England at 3d. per cup and saucer. These were stamped " Mode in England," which was clearly an attempt to lead purchasers to think that the articles were actually made in this country. The real trouble here, of course, is that the articles are made by labour paid at such an extremely low rate that little short of prohibition will assist the British manufacturer.

Low Wage Competition.

Up to the present, we engineers have been largely immune from this low-waged competition, but from a recent publication of the F.B.I., entitled " The Menace of Japanese Competition," we are now threatened with it. It publishes a letter which is being circulated in foreign markets by agents of Japanese exporters, in which they explain why they are concentrating on the export of Japanese machinery and ask for first-class firms to correspond with them. The list of machinery they offer is as follows :—

Wool, cotton, silk spinning and weaving plants, dyeing, bleaching, printing and finishing machinery, humidifiers, air blowers, air compressors, ice-making machinery, steam boilers, steam turbines, generators, motors, Diesel and oil engines, locomotives, road rollers, conveyors, water pumps, chain blocks, electric hoists, ball bearings, machine tools, leather and rubber belts, &c.

With regard to our trade relations with our own Dominions, and the problems which are raised by the various tariffs they impose, it is difficult for the British manufacturer, even if he has visited some or all of the Dominions, to put himself in their place and understand these tariffs from their point of view.

We most of us have experienced the difficulty, for example, of exporting to Australia, having in mind the high tariffs which that Dominion imposes, though we are all familiar with the serious financial difficulties from which she has suffered. It is therefore gratifying to us all to read, as we have recently done, of the greatly improved position disclosed by the Australian Prime Minister's Budget speech, and we are glad to note that the tariff question is under review.

As far as one can gather, the modifications refer to the question of primage,[†] and the compensation which they give themselves on account of the fall of the Australian pound compared with sterling, which we may refer to broadly as difference in exchange. The exact advantage to the British engineer will not be clear until further details reach us, but it is hoped that they will be found to alleviate some of our difficulties in endeavouring to export our machinery to them, and that their improved financial results will enable them to increase their purchases from us.

Frozen Credits.

The financing of orders from foreign countries still causes us grave concern, and what we know as " frozen credits " greatly discourage us in attempting to export to certain foreign countries, on account of the difficulty in getting payments transferred to us.

As an example of the kind of thing a British engineering firm has to contend with in conducting its export trade, I may cite a case in which certain machinery was exported to a South American country as stock for future sale by the manufacturer's own sales organisation on the spot, and was soon rendered unsaleable in that market by a Government prohibition of the importation of certain raw materials essential for the use of the machinery. The British exporting manufacturer thereupon took steps to re-export his machinery for sale in other markets, but was stopped by a Government prohibition which made such exportation conditional upon the exporter guaranteeing to return into the country the equivalent value in foreign money or goods. In other words, he was prevented from recovering possession of his own property in respect of which no payment had been made by anybody in the country to which they had been exported.

There is no doubt that several of my hearers could supply, from their own experience, similar examples of the difficulties we come across in endeavouring to increase our exports.

Trade Improvement and Employment.

I have referred to the signs of an improvement in trade, and it is gratifying to note that this is evident in our basic trades, when tested either from the standpoint of output or of the reduction in unemployment. This is, happily, true for iron and steel, coal, and different branches of engineering, and even for that important industry of shipbuilding, which has so long suffered from the absence of orders and from the pernicious effects of subsidisation by foreign countries.

It is a painful reflection, however, that the financial results up to the end of last year, as disclosed by the figures published in our September *Bulletin*, show that the earned profits of fifty-seven representative engineering and allied firms, representing a total of paid-up capital of £127,000,000, fell to the unprecedentedly low figure of 1·1 per cent., and that although the average amount distributed in dividends was 2·8 per cent. of the paid-up capital, it was equivalent to more than two and a-half times the earned profit. It is obvious that this must have involved a serious draft on already depleted reserve, which in some cases must now be approaching exhaustion. It is to be hoped that when the figures for 1933 are available they will disclose a more satisfactory and sane result.

One avenue of development on which much has been written is that of our expenditure on public works, and while we undoubtedly agreed with the National Government's condemnation of sporadic expenditure on roads and similar objects at the time, thoughtful men are now inquiring whether there is not a case for a more detailed examination of the matter from the point of view of encouraging certain works which might be proceeded with by municipalities, where the expenditure would directly assist our basic industries of iron and steel, coal, and engineering.

Objects which suggest themselves are the local electrification of railways, as opposed to the more ambitious problem of main line electrification ; or a re-study of the problem of water supply, which is now being examined by a committee of the Institution of Mechanical Engineers—not, indeed, on so bold a basis as a water grid, but an examination from the point of view of numbers of local centres where a central water supply could be extended to serve large adjacent areas, to the advantage of the population, as this summer has shown, and with an extension of employment in our engineering industry and the basic trades.

The same observations would appear to apply to extensions of the gas supply under pressure in outlying areas by municipalities and gas companies. If some encouragement were given to the suppliers of gas, as the Government has done in the case of electrical undertakings under the grid scheme, but limited to a wide enlargement of their powers of supply in local areas, it would probably be found to be of national advantage and would undoubtedly help engineering and the basic trades.

Cut-throat Competition.

This leads me to another reflection, based on experience, with which I am sure you will concur, namely, that there is too much cut-throat competition. There are too many unhappy illustrations of taking orders at a loss, and this financial folly must, in the long run, be disastrous. It leads one to express the hope that the B.E.A., with the growth of the group system, can take steps by consultation and wise organisation to bring about a state of things where a fair price is paid for honest design, high efficiency, and good workmanship. The B.E.A., supported, as it should be, by the whole engineering trade in this country, could do much to bring about such a change, to the advantage of employers and employed alike.

Conditions of Contract.

There is another matter which directly affects us all, and that is the unduly onerous and unfair conditions of contract and unsatisfactory terms of payment which we so often find in specifications submitted to us.

One illustration which recently came before me deals with the vexed question of consequential damage. The specification reads :—

> " The contractors undertake to indemnify the purchasers against all damages, expenses and losses which may result as a consequence of partial or complete non-compliance with the clauses of this schedule of conditions, or of bad workmanship or bad quality of materials used . . . "

Another, which illustrates the extreme powers the engineer demanded in regard to materials, says :—

> " The engineer, if he thinks fit, shall send a representative to inspect the manufacture at any stage, and the contractor must send the engineer two copies of the orders for the material sublet.
>
> " The engineer shall have power to take independent tests of the material, to be carried out by some person appointed by him at such place as he may determine, and from the results of such tests there shall be no appeal."

The absence of any provision for a fair arbitration clause is also still too common. Surely the day has gone past, for example, when the chief engineer of any undertaking should arrogate to himself the position of being the sole arbiter of the circumstances when deductions shall be made or penalties applied. Surely it is only reasonable that where penalties are exacted for late delivery, a corresponding bonus should be paid to the manufacturer for earlier delivery.

Here, again, I would like to acknowledge, on behalf of engineers generally, the work which has been done by the B.E.A. in regard to the improvement in contract conditions, and particularly the diligent and persistent efforts which have been made in this direction by Mr. Bremner himself, as Chairman of the Committee of F.B.I., dealing with this important matter.

---

[*] Address at the Annual Meeting of the British Engineers' Association, Thursday, October 12th, 1933.

[†] Primage was originally a small charge made by the captain of a vessel for the use of tackle, &c., but in Australia has become an extra duty charged on the c.i.f. price of goods. In July, 1930, it was 2½ per cent., in November of that year 4 per cent., and subsequently it became 10 per cent., when the duty on British machinery was fixed at 45 per cent. It is now to be reduced.

Exhibitions.

One other point of importance to us, and I have done. It relates to exhibitions and fairs. Under the conditions which at present obtain, we frequently find ourselves in a dilemma which forces us to take part in an exhibition because there is no machinery by which we can come together and discuss the wisdom of that action amongst ourselves, and we are therefore driven to the expense of an exhibition simply because "the other fellow is showing." Could not the weight of this Association be thrown into a movement for one really strong engineering exhibition, preferably held every two years, in which all branches of engineering endeavour to combine so as to show, at reasonably recurring periods, the best that England produces ?

The B.E.A.

Regarding our own Association, there have been growing evidences during this year of the excellent work which has been done ; work which often redounds to the advantage of engineering firms who are not assisting in the cost of running our organisation. Take, for example, the question of tariff boards in our Dominions, where our Association is not yet financially strong enough to do what it would wish. I picture the time when we shall be able to maintain our own representatives in Australia and Canada, armed with all the information necessary to enable them to represent fully the wishes of our members in regard to any type of manufacture where we think that, at present, the scales are weighted too heavily against us, and where we are in a position to prove that a modified attitude on the part of the Dominion concerned would be of benefit not only to the British manufacturer, but to the purchaser in that Dominion.

I would again reiterate the hope I have expressed previously that the advent of better times, which we can surely see now, will bring such an influx of members to our Association that we can tackle many other tasks which are still on our programme, and which, up to the present, have been left undone for lack of that strong national support which we deserve.

Industrial Heating Congress.

The problem of securing the greatest economy in oil and coal combustion and of making the most of poor fuels is regarded as of the highest importance on the Continent, where the economic future of countries possessing limited supplies of fuel, often of inferior quality, is believed to depend upon its solution. So vast is the range of questions involved in this discussion that no fewer than 150 papers were presented at the third International Congress on Industrial Heating, which was held in the Conservatoire des Arts et Métiers in Paris last week. The inaugural meeting was presided over by Monsieur Walckenaer, in the presence of Monsieur Henry de Chatelier, Monsieur Charpy, and other distinguished scientists and metallurgists.

A matter that received immediate attention was the utilisation of low-grade coal at some of the Continental collieries, notably in the North of France, where the coal is won with a high percentage of slack which must be used profitably if the industry is to be placed on an economical basis. The slack is employed in power stations at the collieries, and it is hoped that a demand will be found for it with burners for ovens and furnaces, while a communication on the successful briquetting of lignite in Germany with a press exerting a pressure of 12 tons per square inch on special moulds suggested the possibility of something being done to make briquettes of small coal without the use of binding material. Semi-carbonisation processes were naturally discussed. Monsieur Charles Berthelot said that experimental work in that direction had cost something like 2000 million francs and that about 2000 types of furnaces had been invented, of which not more than a dozen had given satisfactory results. Nearly all the French collieries are producing semi-coke, but are making little out of the liquid by-products, and the only hope for semi-carbonisation lies in popularising the use of coke for domestic heating which the colliery companies are making great efforts to accomplish in competition with gasworks coke. According to Monsieur Simonovitch the experience in Belgium is that semi-coke produced by low-temperature carbonisation is of excellent quality for domestic heating, but that it must be sold at a low competitive cost, which means that a profitable outlet must be found for the tar. It is a general complaint that only a relatively small proportion of the tar is saleable. There are, said Monsieur Simonovitch, enormous possibilities in low-temperature carbonisation, but he questioned whether distilled oils could compete normally with natural oils.

Amongst the papers on economical combustion that of Mr. David Wilson on the results of the latest developments in steam generation in England was practical and informative, and he concluded by saying that he had reason for believing that a new process, to be applied on a large scale, was likely to prove of great importance from the point of view of economy and would, perhaps, rival pulverised coal. The idea of raising combustion temperatures by the simultaneous use of two different fuels was put forward many years ago, and it is only recently that tests have been carried out methodically with the system, alike for steam raising and in internal combustion engines. One such application was described by Monsieur Joulot, who gave an account of an incineration plant in conjunction with an electrical power installation working on this principle which was put in operation at Bordeaux in February last. Steam for the power plant had to be raised either with a mixture of coke breeze and Welsh coal, or by the incineration of 100 tons of town refuse a day, or by a combination of the two. There are three Babcock and Willcox boilers of 600 square metres heating surface with superheaters and Green economisers, and each has a Babcock and Willcox double mechanical grate and four refuse-burning grates of the Heenan and Froude type constructed by the Société "Union des Services Publics" in Paris. The gases from the refuse grates pass into the combustion chamber above the mechanical grate with an apparently greater density owing to their lower temperature, and the whirling effect obtained ensures a perfect mixture and complete combustion. The efficiency tests of the plant are still in progress.

Examples of what can be done with the economical working of marine engines were given by Monsieur Roger Martin, laboratory director at the Office Central de Chauffe Rationelle, who said that without any modification of boilers their efficiency could be greatly increased by a more careful supervision of working with the aid of temperature and other control instruments. There was no necessity for a costly installation. Only a few essential instruments were required, and a little care on the part of those in charge of the boilers would produce notable results. In one case, a 9000-ton cargo ship with 1500 horse-power engines increased its speed from 8 to 10 knots with the same fuel consumption because control instruments allowed of the boiler being worked to give something like its best efficiency. In a passenger ship with engines of 9000 horse-power the installation of a few control instruments was followed by a reduction of 35 per cent. in fuel consumption. Similar results were recorded in other ships over long periods. The point stressed was that the merchant marine did not attach the same importance to the value of temperature and gas control as is customary in steam-raising practice on land, and yet on cargo ships fuel economy may be, at the present time, the only determining factor in profitable working.

The problem of propelling aircraft by steam was presented in a somewhat novel manner by Monsieur Rabinovitch, who pointed to the possibilities of highly efficient turbines with high steam pressures and temperatures. For high powers the turbine can compare with the petrol engine, with the further advantage of flexibility and of running at great altitudes. The weight of the turbine could be reduced by the use of high resistance steels in the same way as had been done with the petrol engine ; but while there appeared to be no reason why the steam turbine should not be developed in that way, its evolution would probably take as much time as that of the present type of aviation engine. Nevertheless, Monsieur Rabinovitch thought that the matter was worth investigating in the case of passenger-carrying machines. He made no mention of the steam generator and water supply. The aviation engine was also the subject of a communication by Monsieur Clerget, who has been for some years working out the problem of the heavy oil engine for the French Air Ministry. He spoke of experiments he had carried out with the simultaneous injection of two different liquids, which had already given encouraging results and indicated that there is something to be done in this direction. A 2·61 litre engine running at 1900 revolutions per minute developed 14·5 horse-power with gas oil, the consumption being 199 grammes per horse-power and the thermal efficiency 30 per cent. With the same engine a simultaneous injection of 109 grammes of oil and 89 grammes of alcohol gave a thermal efficiency of 39 per cent. Monsieur Clerget thought that the double fuel injection might change completely the characteristics of the present type of compression-ignition engine by giving to it a higher efficiency and flexibility and tending to a reduction of weight comparable with that of the petrol engine. In summing up the discussion on this matter, Monsieur Dumanois, who is a leading authority on internal combustion engine research, and is at the head of State fuel and other technical services, mentioned, incidentally, what had been done in the way of burning pulverised coal in engines. He seemed to imply that it might be worth while to continue experiments with the injection of pulverised coal with some liquid fuel. The introduction of the high-speed compression-ignition engine led Messrs. Boerlage and Broeze, engineers at the Delft laboratory of the Bataasche Petroleum Company, to issue a warning with regard to the future supplies of special oils required for such engines. In the original slow-running type of solid oil injection engine the quality of the ignition, or the timing of it, had no effect upon the working, but with increased speeds this quality has to be taken into account. The higher the speed the greater is the care necessary in the selection of fuels, and as there is available only a limited quantity of the special oils employed for high-speed engines there is a risk of the price going up and even of supplies being monopolised for aviation purposes.

The cost of electricity produced by heat and hydraulic power plants was shown in a diagram prepared by Monsieur Stoeffler, wherein it appears that at about 800 hours of supply per year the cost per kW at the hydro-electric station is 29 centimes, and at the heat power station 22·7 centimes, while at 8000 hours the cost of the hydro-electric production is 4·8 centimes and of the heat power production 7 centimes. The curves coincide at 3355 hours with 9·58 centimes. Heat plants have an advantage in lower capital charges. As the distributing companies do not take current for more than 2500 hours per year, the economy is on the side of heat power stations. Another aspect of the relative situations of heat and hydro-electrical generating stations was given in a communication by Monsieur Dauvergne, who considered them from the point of view of the influence they exert on wages. He concluded that new hydraulic concessions for electrical production should only be granted in cases where current can be supplied at below the price of the heat power station supply so that the benefit accruing to the consumer will compensate for loss in wages. Hydro-electrical plants should be regarded as supplementary to heat electrical generating stations and not be in competition with them.

An unusual heat engine was recently devised by the Westinghouse Electric and Manufacturing Company for exhibition at the Chicago World's Fair. A small bi-metal disc snaps from concave to convex form as its temperature is raised to about 400 deg. Fah., and snaps back to concave shape when it is cooled below 255 deg. Every 10 seconds the "kick" of these snaps tosses the disc, which is fastened to a freely swinging arm, to and fro between a highly heated stove-like cylinder on one side and an ice-cold cylinder on the other. A maximum speed of 2000ft. per second is reached, or about 23 miles a minute.

The Holmes Jubilee.

Among the pioneer electrical firms that began in a very small way and are still in business, that of J. H. Holmes and Co., Ltd., now of Hebburn-on-Tyne, has always held a prominent position. It came into existence as a private concern in 1883, and this year therefore marks its jubilee. With a single workshop and a staff composed of one man and a boy, the initial activities consisted of providing electric light for houses, factories, and steamships. A private plant installed in the house of Mr. W. H. Holmes, the father of the present Mr. J. H. Holmes, gave rise to lengthy articles in the local newspapers, for it was the first house in the Tyneside district to have a permanent supply of electricity. Current was provided by a half horse-power gas engine driving a Siemens dynamo, working in conjunction with a battery. Later, a 25 horse-power plant was installed at Jesmond Towers, Newcastle, the battery being used to motor the dynamos when starting the engine. Before the end of 1883 the firm had completed an arc lamp lighting installation at the Silloth dock works, and had supplied lighting equipment for the "Nonpareil," the first mercantile marine steamship built on the Tyne to have such an equipment. An interesting feature of the side-light fittings was that they were provided with automatic apparatus for bringing new lamps into circuit in the event of old lamps failing.

A special effort was made in 1884 to bring the advantages of electric light to the notice of the public. In January of that year the firm purchased a portable plant, complete with boiler, and made it known by means of circulars that it would undertake the work of providing temporary electric light installations at public gatherings or in private residences. Thus it came about that after a short time no bazaar in the neighbourhood of Newcastle was considered complete or up to date without this new system of lighting. On the occasion of the visit of the Prince and Princess of Wales to Newcastle in 1884, in connection with the opening of Jesmond Dene to the public, this portable plant was used to supply current to an arc lamp in the lantern tower of St. Nicholas's Cathedral.

During the same year the firm began to build its own dynamos and motors. The first machine, completed in 1885, ran in Ireland for about thirty-five years, after which it was exchanged, rather against the owner's wish, for a modern machine in order that the original dynamo might be put in the works' museum. Later, it was transferred to the Newcastle Municipal Museum of Science and Industry. In those early days, dynamo design was more or less a matter of guesswork, but in 1886 a great advance was made by the reading of a paper before the Institution of Civil Engineers by Gisbert Kapp, who showed how the necessary dimensions, number of turns, &c., for a given output could be calculated. The new principles laid down in that paper enabled J. H. Holmes and Co. to begin the manufacture of a new range of dynamos, the first of which was put in hand in May, 1886. Various improved features were introduced, and outputs began to rise until one machine was produced with an armature 17in. in diameter. Its output was 38 kilowatts at 450 r.p.m., and in view of the abnormal dimensions, it was christened "Jumbo." The name "Castle" was registered as the firm's trade mark for dynamos and electrical instruments. Many of the early dynamos were used for lighting picture galleries, theatres, and dining-rooms, and their successful operation at the 1887 Newcastle Exhibition resulted in orders being received from many parts of the country.

The quick break switch, which in much larger sizes and in modified forms now serves for controlling electric circuits under all sorts of conditions, was invented by Mr. J. H. Holmes in 1884. On the occasion of the opening of a new café in Wallsend, Mr. Holmes' attention was directed to the danger of forming an electric arc in a wooden switch-box by breaking the circuit slowly, and in consequence the quick-break switch was devised. Other inventions followed, and the firm's business continued to increase. A new factory was built in 1887, and was subsequently extended.

Whilst in Egypt in 1889 Mr. Holmes gave attention to the requirements of vessels proceeding by night through the Suez Canal. For the benefit of vessels without electric light, he introduced a portable lighting equipment, which was hired out by the coal shipping companies. It consisted of a steam engine coupled to a dynamo and fitted in a cage with a lifting eye, so that it could be slung on to the deck of a vessel and be connected up to the steam supply by means of piping with universal joints. In this way the capacity of the canal was effectively increased.

Electro-plating dynamos, including one designed for an output of 3000 ampères at 5 volts, were among the comparatively early Holmes' machines. During 1897 the firm acquired the patent rights for the "Lundell" electric motor, which had already met with widespread application in America, especially for driving small fans and printing machinery. In the latter field the machine soon met with favour in Great Britain, which had hitherto given little attention to electric motive power. In 1898 the patented Holmes-Clatworthy system of electrically driving newspaper presses was introduced, and the first equipment, which was followed by many more, was installed in 1899. More recent products, such as arc-welding sets and A.C. commutator motors, have been described from time to time in our columns.

When in 1928 the original private partnership of J. H. Holmes and Co. ceased to exist, the work was carried on by J. H. Holmes and Co., Ltd., in the old factory in Portland-road, Newcastle-on-Tyne. Two years after the change, however, new works were built adjacent to the existing New Town Works of A. Reyrolle and Co., Ltd. The Holmes works have since been incorporated in those of the latter firm, and manufacture is now carried out with the most modern plant and equipment.

In these days of super-power stations, extra-high-tension transmission, and all the ramifications of modern electricity supply, the work of pioneers is apt to be overlooked, but those who have witnessed the developments of the past fifty years rarely fail to appreciate a little history. Those who, like Mr. J. H. Holmes, began when there was little, if any, data to guide designs, must have had to face many difficulties and disappointments, and they have every right to be proud of their achievements.

Coal-Oil Mixtures.

In a paper read before the Institute of Marine Engineers on Tuesday evening, October 17th, Dr. W. R. Ormandy and Dr. J. Burns dealt with the recovery of oil from coal. They treated the problem from both the national and Empire standpoint, and considered the present position of the gas and coke oven industries, also the low-temperature carbonisation of coal and the hydrogenation of coal and coal tars. The last section of the paper, which dealt with the recent progress made in the production and application of coal oil mixtures, is reproduced below.

Coal-oil Mixtures.—Attempts to produce stability in coal-oil mixtures have proceeded along three main lines :—

1. By grinding the coal in oil to colloidal dimensions.
2. By protecting coal particles suspended in oil by gel-forming materials, such as oil-soluble soaps.
3. By "peptising" the coal particles by means of coal tar distillates.

Granted that complete success is or can be attained in the production of a stable coal-oil mixture, it is interesting to discuss the possible application of such mixtures and the extent of such applications. Present-day indications are that the coal-oil mixtures will be used solely for steam-raising purposes, though claims have been made that such fuels are suitable for use in compression-ignition engines. In view of the fact, however, that the ash content allowable in a Diesel fuel is of the order of 0·2 per cent., it is clear that the coal employed would have to be, to all intents and purposes, free from ash. In fact, an ash content lower than the inherent ash of bituminous coals would be necessary, which ash it is impossible to remove mechanically.

In so far as the application of coal-oil mixtures for steam-raising purposes is concerned, it is probable that such application will be confined to marine purposes, where the handling and storage advantages are of prime importance and a liquid fuel enjoys a premium over a solid fuel. Fuel oil has no real advantages over coal or pulverised fuel for stationary steam-raising plants except in a few isolated cases. This attitude, it is interesting to note, is taken, not only by the coal producers, but is also recognised by some of the leading authorities in the oil world. Mr. J. B. Aug Kessler, in his admirable lecture given at the recent World Petroleum Congress, deals at length with what he terms legitimate and illegitimate uses of oil, and he undoubtedly deprecates the forced sale of mineral oil for use where coal is obviously more suitable, having regard to economic factors. Further, the present uneconomically low prices for fuel oil are not likely to remain when the oil producers put their house in order and rationalise the output of crude oil.

The quantity of fuel oil employed for steam-raising purposes in the mercantile marine and Navy at the present time amounts to approximately one and three-quarter million tons per annum. If we assume the general use of a mixture consisting of 60 parts of oil with 40 parts of coal, the coal requirements in excess of present-day requirements would amount to approximately one million tons. It will be appreciated that this figure represents only a very small percentage of the total yearly output of coal, which approximates on an average to 230,000,000 tons. It is well to keep these facts in mind when considering the rather exaggerated claims made as to the benefits to the mining industry which would accrue from the general adoption of coal-oil mixtures. It is generally accepted, too, that the most suitable type of coal for the preparation of coal-oil mixtures is the soft, easily ground bituminous type of reasonably low ash content, and washed slack of this type of coal would answer the purpose. Thus the development of coal-oil mixtures would provide an outlet for a type of coal which must be raised and for which at present there is not sufficient market. This market, however, would be a true market and not one which would be developed at the expense of another grade of coal.

There are obvious difficulties to be overcome before the use of coal-oil mixtures for marine purposes could become general. In the first place, it is doubtful if a degree of stability of the mixture could be attained which would allow of the mixture being prepared at one central station and shipped in tankers and stored at foreign ports where oil is available at the present time. The alternative is the setting up of grinding and mixing stations at widely separated centres, which in turn involves the transport of coal to such centres. It is more likely that coal-oil mixtures will be confined to coastal traffic or wherever fuel can be bunkered for a round trip. For ocean-going vessels there is nothing to prevent the outward trip being made with coal-oil fuel and the home trip with straight fuel oil, as the handling, storage, and burning equipment is the same in both cases.

In addition to the recognised methods of producing stable coal-oil mixtures, there is another phase of activity in this direction which merits attention. Much work has been done and is being done on the heat treatment of suspensions of coal in oil. It is claimed that, under the conditions employed, yields of low boiling oils can be obtained from coal greater than can be got by low-temperature carbonisation methods, while the remainder of the product from the treatment, after distilling off the low boiling fractions, is in the form of a highly stable coal-oil mixture. In some cases it is claimed that the heat treatment of coal in suspension in oil gives the coal particles a spongy-like surface with a considerable diminution in the apparent specific gravity of the particle, leading to the production of a stable coal-in-oil mixture. In other cases it is claimed that under the specific conditions of treatment the coal particles are actually disintegrated and are more nearly reduced to colloidal dimensions.

One must regretfully admit that science and technology working together tend to reduce the amount of fuel consumed rather than to increase it. Existing industries using coal achieve their object with less coal than was formerly employed, and the increase in trade which might have been expected has not yet resulted. The gas industry has increased its output of gas and coke very steadily for a number of years, and this without the necessity for purchasing more coal. The increased sales have been met by the improvements in the control and design of the manufacturing plants employed.

In considering the coal situation of the country it is necessary to keep a balanced outlook. Many schemes are being put forward which involve millions of capital, without the repercussions of the development of such schemes being fully appreciated. In any case, it is well to remember that the lighting up and working of two modern large blast-furnaces would lead to an increased demand for about one million tons per annum of coking slack. A slight recovery will produce effects on the coal industry, which it will take new industries, of the types dealt with in this paper, many years to equal.

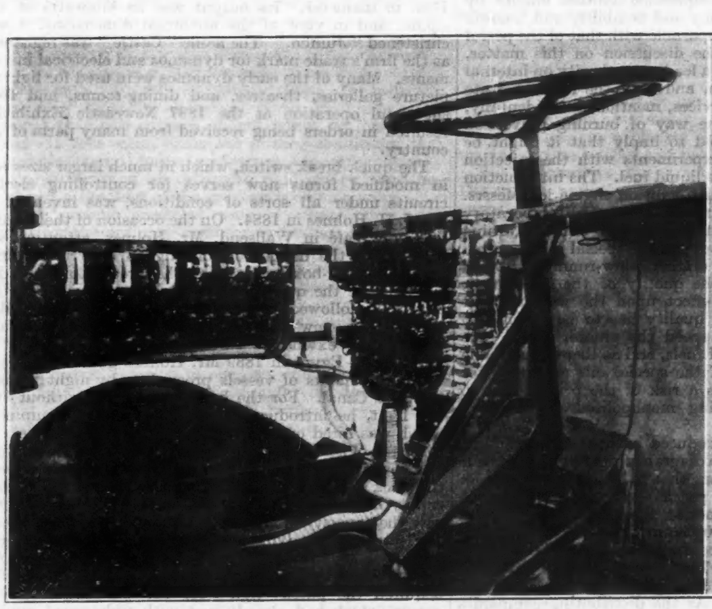
Regenerative Trolley Omnibuses.

The use of regenerative control equipments on trolley omnibuses appears to be rapidly increasing. Apart from B.T.H. regenerative equipments already in service, others are being supplied. Four are on order for the Huddersfield Corporation and fifteen for the Walsall Corporation. Two of the Huddersfield vehicles are being fitted with B.T.H. motor and control gear to the order of Karrier Motors, Ltd., one with exactly the same equipment to the order of the Sunbeam Motor Car Co., Ltd., and one with B.T.H. control gear to the order of Ransomes, Sims and Jefferies, Ltd. The regenerative control gear and motors are similar in all respects to those supplied by the B.T.H. Company to the Sunbeam Motor Car Company for its Walsall Corporation contract.

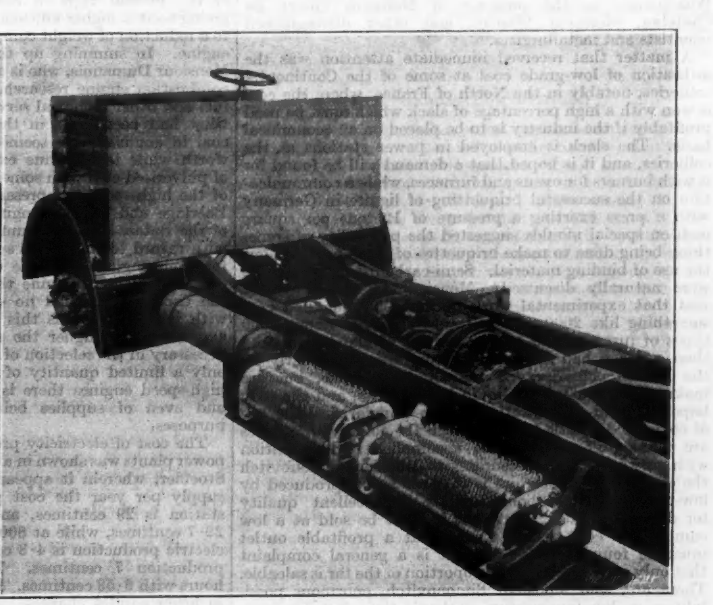
The left-hand illustration above shows the contactor panels and master controller mounted in the driver's cab. To facilitate wiring, and to enable the connections to be examined, the wires are run on the front of the panels. The wiring of the various parts of the equipment was carried out by the Sunbeam Motor Car Company, the cables being drawn into flexible steel tubing as shown. The shunt field contactors mounted on the front dash open and close against rubber buffers and are practically noiseless in operation. The patented B.T.H. gearless master controller is coupled to a special pedal plate mechanism designed by the Sunbeam Motor Car Company, and requires a very light pressure to operate it.

The motor, to be seen in the right-hand illustration, which also shows the main resistances, is the makers' latest light-weight type of machine. It is sufficiently compact to be mounted under the floor of the vehicle, and apart from the fact that it is very accessible, the drive to the back axle is short. Vitreous enamel tubes mounted in a frame with a louvred cover are used for the shunt resistance.

As shown in the right-hand illustration, the main resistances are mounted at the side of the chassis. They are of the B.T.H. rustless unbreakable type, and are particularly suitable for road vehicle service. Connections are made from the resistance grids to a terminal bar mounted on the U-shaped end frame, and incoming leads are brought to a point between the two boxes where access to the terminals can readily be gained. While the resistances are protected below from the ingress of dirt and moisture, air is free to pass through from the front to ensure adequate ventilation.



CONTACTOR PANELS AND MASTER CONTROLLER IN DRIVER'S CAB



MOTOR AND MAIN RESISTANCES

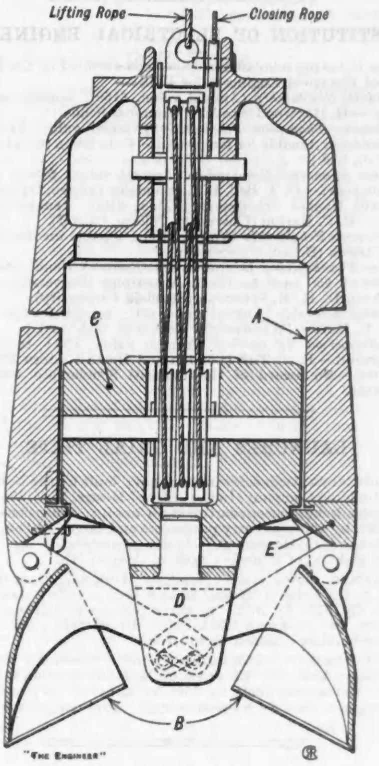
A New Microphone.

A new carbon microphone for which important advantages are claimed has been introduced by Marconi's Wireless Telegraph Company, Ltd. It has been designed to meet the demand for a reliable low priced instrument, with good operating properties, and is said to be practically free from background noises. The microphone consists of a double-cell capsule, with a light diaphragm, the complete instrument being suspended within a light but robust metal frame, which can be suspended or be inserted in a pedestal or in a hand grip, according to requirements. The carbon depth which regulates the frequency response has been carefully chosen to give a satisfactory response over the whole useful frequency range, and as the height of each cell is only 2·5 cm., the tendency to pack is considerably reduced. As the instrument is effectively sealed, its characteristics are not affected by weather or temperature.

Extensive tests are said to have shown that ground noise is of the same order as normal speech at about 50 m. from the microphone. Owing, moreover, to the fact that the carbon microphone requires no immediately adjacent amplifier unit with its attendant sound baffle effects, the polar diagram of response at different frequencies is considerably better than that of the condenser instrument. The new instrument has an exceptionally wide angle of pick up. When used with a suitable transformer and a current of approximately 25 milliampères, the voltage produced at the grid of the first valve of the amplifier is about 100 millivolts, with speech at about 25 cm., as compared with 3 millivolts given by a standard condenser microphone. Owing to the large output of the microphone, considerable lengths of cable can be used between the instrument and amplifier without risk of induction. No adjustments are needed, and the microphone has been made suitable for the same terminal connections as those for the Marconi Reisz microphone. The new instrument can therefore readily take the place of the latter, and, if necessary, as many as four microphones can be connected in parallel.

A Small Excavating Grab.

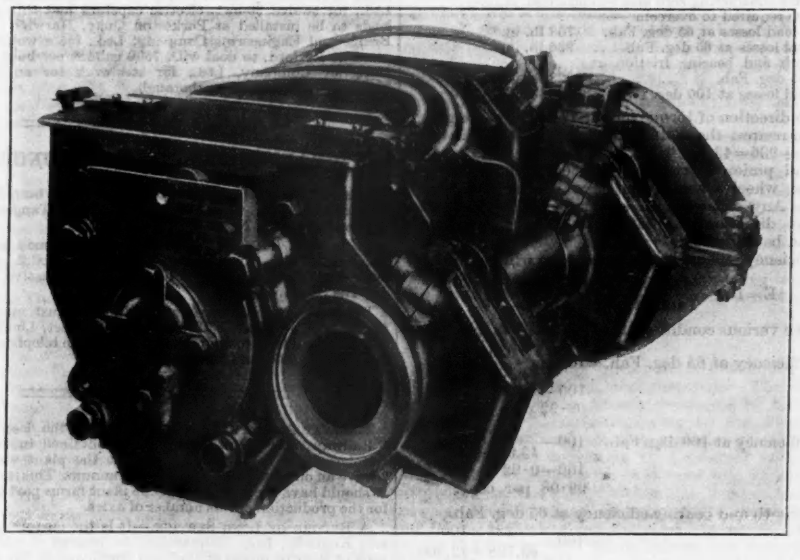
In the September issue of *Science et Industrie*, of Paris, there is described and illustrated (we reproduce one of their illustrations) a little excavating grab, which is obviously specially applicable to such services as helping in the sinking of hollow piles or tube wells. It is intended to be only from some 6in. to 12in. in diameter and consequently its mechanism has to be very compact. In consequence reliance for the digging action is not placed on the usual system of compound levers, but the grab is provided with a massive shell A, which is of sufficient weight to drive the buckets B into the soil, and is so strongly constructed that it may be dropped to drive the buckets into the ground. The heavy piston C assists in this action and also ensures the opening of the buckets. Closing of the buckets, when they have penetrated the soil, is effected by the rope tackle drawing up the piston and the bucket arms. It will be noticed that there are slotted holes for the pins at the end of fork D. The buckets are pivoted to the ring E, which is readily detachable from the shell A, so that alternative arrangements of buckets may be employed according to the class of soil being dredged.



Excavating Grab

Electric Tramcar Equipments.

The traction department of Crompton Parkinson, Ltd., is delivering thirty sets of "Crompton West" electric tramcar equipments to the Liverpool Corporation. The motors are being made at the Chelmsford works and the controllers and circuit breakers at the Brighton works of Allen West. Each of the new cars for which the equipments are being constructed will be provided with four 36 H.P. motors of the type illustrated. Two of each of the four machines will be permanently connected in series, and the two pairs will be arranged for series-parallel control in the ordinary way. A special feature of the motors is that they are designed to permit of a lower car floor level than usual. They are light-weight, box-frame, interpole, self-ventilated machines. In the interior light alloy metal is employed wherever possible, and also for the gear case. Steel inserts are provided at all points of attachment. Class "B" insulation is used throughout, the armature and field coils being bakelised to make them impervious to moisture, accurate to size, and to give them good heat-dissipating qualities. Quiet running is secured by the use of grease lubrication and by the dynamic balancing of the armature.



36 H.P. Electric Tramcar Motor

An improved parallel flow self-ventilation system differs from that normally adopted in that the two streams of air for cooling the armature core and coil surfaces respectively are kept separate throughout their passage in the machine. In this way the correct air flow required can be provided in either path, and another special point in the design is that care has been taken to arrange the air inlets so that foreign matter cannot gain access to the interior of the motor.

The cam-type controllers have four series, four parallel, and six rheostatic brake notches. The rheostatic brake operates in conjunction with the air brake, and both are controlled by the main controller handle when moved to the brake position. In place of the usual air brake attachment on the controller cap plate, the air-brake-operating mechanism is built integral with the controller top.

An improved single-spring notch regulator mechanism not only operates on all the power notches, but can, if necessary, be arranged to operate in connection with the cut-off of the air brake before the controller is moved to the first power position. The main operating handle drives through gearing a horizontal drum, which is continuously rotated and forms the controlling connection with the motors for motoring and braking. At the end of the brake drum shaft spur gearing drives the horizontal cam shaft, and with this arrangement it is possible to provide ten contactor units without making the overall width of the controller greater than that of other types of controllers having a smaller number of contactor elements. The increased number of contactor elements enables improved circuit arrangements to be provided, thereby ensuring that all arc rupturing is confined to the contactor units and never occurs on the drum contacts. Each contactor element has a blow-out coil built up into a complete unit, which can readily be removed from the controller for inspection of the contacts, the controller being isolated at the same time.

On the lower horizontal shaft there are two co-axial drums. One is the reverser drum controlled by a separate removable reverse key on the cap plate. In addition to the contacts for reversing the motors it carries contacts for sanding during run-back braking, and for the warning lights which are connected in circuit at each end of the car when rheostatic braking is employed. The other drum is for isolating either pair of motors on the occasion of a fault, while permitting full operation of the remaining machines. Two overload adjustable circuit breakers are being fitted to each car, the adjusting device being sealed to prevent unauthorised settings.

Canadian Engineering News.

Highways.

In keeping with its good roads policy, Canada's expenditure last year on highway construction amounted to 45,867,491 dollars, including subsidies from the Dominion Government for relief work and for the elimination of rural level railway crossings. Expenditures on bridges and ferries amounted to 4,164,018 dollars, making a total expenditure of 50,031,509 dollars. Heavy expenditure in Northern Ontario included much clearing of bush, establishment of construction camps, &c., for the Trans-Canada highway. The surfaced highway mileage in Canada at the end of 1932 amounted to 91,312 miles and unsurfaced roads to 307,008, making a total of 398,320. This total includes all roads outside incorporated cities, towns and villages under the jurisdiction of the Provincial Highway Departments. Gravel roads increased from 75,081 miles to 80,183. Cement concrete roads are found almost entirely in Ontario and Quebec, only 3 per cent. of the total being in other provinces. The increase in this high-class type of road was 433 miles, or from 1584 to 2017 miles.

Engineering Standards.

The Dominion Department of Public Works recently included in the standard form of contract a clause referring to the standards of the Canadian Engineering Standards Association, reading as follows :—"Unless otherwise expressly provided in the specification, all goods or materials supplied shall conform to the specifications of the Canadian Engineering Standards Association, or the specifications of the recognised Standards Association in the country of origin in the Empire, and in cases where goods or materials are required, which are not of Canadian production or manufacture, the standards above mentioned shall apply." This action has a direct bearing on the development of Empire trade when it is associated with the Order-in-Council issued by the Privy Council of the Dominion in March last, which stated that whatever material or goods not produced or manufactured in Canada are required by any Government department, or by any contractor engaged in Government work, provision shall be made in the tenders that such material shall be of Empire production or manufacture, and that, where standards are specified, an Empire standard shall be adopted unless it is conclusively shown that goods or materials in question cannot be obtained in the Empire. It was assumed that this applied to the Canadian National Railways, and every board, commission, or other similar body under the control of Parliament. Continued efforts are thus being made to secure harmony wherever possible between Canadian and British specifications covering the same field.

Big Development for Newfoundland.

Work on a 21,000,000-dollar development project for Newfoundland's resources will begin this autumn if it receives the approval of the Government and the Royal Commission investigating the Island Dominion's financial position. The Boston engineering firm of Chase and Gilbert has been retained to make plans for the project, which contemplates the taking over of improvement and development work by a British-Canadian syndicate in return for fee simple rights over certain properties which the syndicate holds under lease.

ENGINEERS' GERMAN CIRCLE.

There was a large attendance of members and friends of the Engineers' German Circle on Monday evening last, when the inaugural lecture was given by Dr. Nägel, of Dresden. The meeting was held in the handsomely reconditioned hall of the Institution of Mechanical Engineers. At an exceptionally busy time, the German Ambassador, Dr. Leopold von Hoesch, found an opportunity to spend a short while with the members of the Circle and expressed his own and his Government's interest in the work of the Circle and the sister Circle of English-speaking engineers in Berlin, which, he said, were bringing together the engineers of the two countries and working for a deeper understanding between the two nations. Dr. Nägel took as his subject research on the process of combustion in high-speed internal combustion engines, and, in a lecture fully illustrated by lantern slides, gave his hearers an insight into his capacity for teaching and the strong spirit of leadership which is shown alike in the research work of his Dresden laboratory and his guidance of the scientific work of the Verein Deutscher Ingenieure. He described the laboratory methods employed for the study of flame propagation in cylindrical bombs and pressure vessels, and the injection of fuel oils into highly compressed atmospheres. He showed that, by means of the oscillograph and quartz indicator, and an electrical method of measuring valve movement, a very complete picture of what happened in the engine cylinder could now be obtained. Examples were given showing possible applications of the knowledge so obtained in the development of the use of tar oils in high-speed airless injection engines, and the problems of starting engines of the ante-chamber type from cold. The lecture was followed by an informal dinner, held at the Anglo-German Club.

CATALOGUES.

Greenwood and Batley, Ltd., Leeds.—A folder illustrating "Greenbat" electric trucks.

Demag A.G., Duisburg.—A 200-page book illustrating and describing the firm's products.

F. A. Welling and Co., Ltd., 8, Union-court, E.C.2.—A booklet on "Cinch" expansion anchor bolts.

Oliver Ashworth and Co., Ltd., Castle Grounds, Bury.—Catalogues of second-hand machinery and plant of all descriptions.

Alfred Herbert, Ltd., Coventry.—A new publication dealing in some detail with the firm's range of capstan and turret lathes.

Fescol, Ltd., 101, Grosvenor-road, S.W.1.—Catalogue N 1 on the electro-chemical deposition of metals by the "Fescol" process.

Colvilles, Ltd., 195, West George-street, Glasgow, C.2.—A brochure on combating corrosion by the use of "Dalzo" rust-resisting steel.

Samuel Fox and Co., Ltd., Stocksbridge Works, near Sheffield.—A booklet entitled "The Case Hardening of Special Steels by Nitrogen."

Thos. Robinson and Son, Ltd., Railway Works, Rochdale. —A book of over 200 pages dealing in detail with the firm's woodworking machinery.

Musgrave and Co., Ltd., Belfast.—Copies of two new catalogues just issued for "U" and "M" type fans, and high-efficiency fans respectively.

Sturtevant Engineering Company, Ltd., 147, Queen Victoria-street, E.C.4.—Publication No. 1243 dealing with industrial process ventilation.

Stedall-Dowding Machine Tool Company, 145, St. John-street, E.C.1.—Pamphlet in English describing the Lindner automatic engraving machine.

James Gordon and Co., Ltd., Regent House, Kingsway, W.C.2.—Pamphlet H 2, dealing briefly with Hagan automatic control for steel and gas works.

A. Reyrolle and Co., Ltd., Hebburn-on-Tyne.—One of the firm's "Multum in Parvo" catalogues containing a set of leaflets describing their products.

Flexotube (Liverpool), Ltd., 2, Strand-street, Liverpool.—A catalogue on mechanical scale removal by motor-driven tube and surface scaling machines, rotary cutters, and brushes.

Westinghouse Brake and Saxby Signal Company, Ltd., 82, York-road, N.1.—The following sections of the firm's new signal catalogue :—Section A, Sub-section D, "Electric Point Detection and Locking" ; Section B, Sub-section B, "Electric Signal Machines and Signals" ; Section B, Sub-section C, "E.P. Semaphore Signals, &c." ; Section B, Sub-section D, "Route Indicators."

Efficiency Tests on 600 H.P. Increasing Gear

By H. E. MERRITT, D.Sc.

SINCE the opportunity of carrying out accurate full-load efficiency tests on reducing or increasing gear units does not often present itself, the data derived from the tests described below may possibly be of interest to both designers and users of reduction gearing.

The units in question were designed to transmit 600 horse-power continuously, increasing speed from 180 to 935 r.p.m., and comprised pinions of 0·55 carbon forged steel, solid with shafts, gearing with wheels having 0·4 rolled carbon steel rims shrunk on to cast iron centres. High-speed and low-speed shafts were mounted on roller bearings and lubrication was by splash. The centre distance was 24in., and the wheel and pinion had 161 and 31 teeth respectively, of British standard 20 deg. pressure angle tooth form, 30 deg. spiral angle.

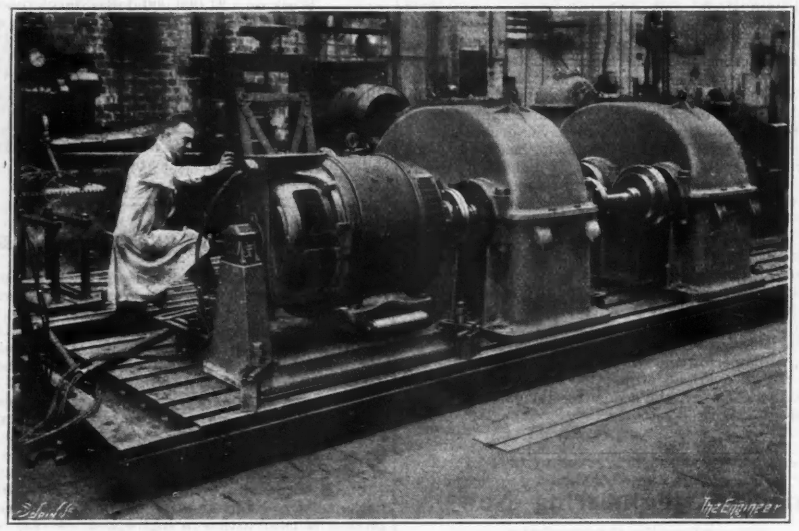

FIG. 1—ARRANGEMENT OF GEARS ON TEST BED

Since two identical gears were required, and full-load efficiency tests were specified before the manufacture of the gears was commenced, arrangements were made to carry out a back-to-back or power circulation test. One pinion shaft was therefore extended and a temporary cover made so that the gears might be coupled up in line.

The wheel and pinion shafts were connected in pairs by high-tensile torsion shafts, one of the couplings on the pinion torsion shaft being left undrilled. Prior to the test proper, one half of this coupling was prevented from rotating and to the other was attached a lever, radius 72in., to the end of which were suspended weights producing, together with the weight of the lever, a torque corresponding to 635 horse-power at 935 r.p.m. This produced, by reason of the flexibility of the torsion shafts, a total angular deflection of one half coupling relative to the other of approximately 3in. at the rim, and in this position the relative positions of the coupling halves were marked. The coupling was then drilled and reamed in this position. Clearly, when the coupling was bolted up in the full torque position, all the gears and bearings would be subjected to full-load conditions, and the power required to rotate this closed system from an external source would represent the total losses in the two gears.

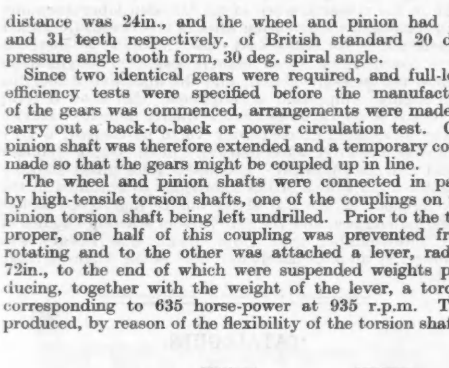

FIG. 2—DIAGRAM SHOWING ARRANGEMENT

For this purpose the drive was taken from a 40 horse-power variable-speed motor with suspended stator, whereby the torque reaction could be measured mechanically by a lever arm and spring balance in the usual way. The general arrangement of the test is shown in the photograph, Fig. 1, and the diagram, Fig. 2.

The tests comprised measurements of the losses with the torsion coupling disconnected and with the oil at a temperature of 65 deg. Fah., followed by measurements of the full load losses at the initial temperature of 65 deg. Fah., and after running for two hours (final temperature, 100 deg. Fah.).

Numerous similar tests on gears of various kinds, mounted on roller bearings, had shown that the total losses in a gear running at constant speed and varying loads could be divided into two parts, namely, a no-load loss representing oil drag in gears and bearings, and constant at all loads, and a net load loss representing the friction due to load between the teeth and in the bearings and directly proportional to the load. On this basis, which from all the evidence is substantially true, the no-load and net-load losses and the gear tooth and overall efficiencies may be determined for any load from observations at no-load and full load.

The observations taken during the tests were as follow :

Pinion speed	935 r.p.m.
Radius of coupling torque arm ..	72in.
Equivalent weight on coupling torque arm..	595 lb.
Pinion torque..	72 × 595 = 42,800 lb. in.
Horse-power circulated through each gear	635
Motor torque arm	35·4in.
Motor spring balance readings—	
No load at 65 deg. Fah.	20·0 lb.
Full load at 65 deg. Fah. ..	26·5 lb.
Full load at 100 deg. Fah. ..	22·5 lb.
(After subtracting zero and windage corrections)	
Torque required to overcome—	
No load losses at 65 deg. Fah.	708 lb. in.
Total losses at 65 deg. Fah. ..	936 lb. in.
Tooth and bearing friction at 65 deg. Fah.	228 lb. in.
Total losses at 100 deg. Fah. ..	796 lb. in.

For the direction of torque for which readings are given, the pinion nearest the motor carried a torque at the teeth of 42,800 + 936 = 43,736 lb. in. at 65 deg. Fah.; whilst the second pinion carries only 42,800 lb. in. The first drove the wheel whereas the second was the driven member. Any difference in efficiency of the gears due to relative direction of rotation and torque is so small that it can be neglected.

The efficiency reckoned as a percentage will be given by

$$E = 100 - \frac{\text{Driving torque} \times 100}{\text{Total of pinion torques}}$$

and for the various conditions is found to be as follows :—

$$\text{Overall efficiency at 65 deg. Fah.} = 100 - \frac{936 \times 100}{43{,}736 + 42{,}800}$$
$$= 100 - 1{\cdot}08$$
$$= 98{\cdot}92 \text{ per cent.}$$

$$\text{Overall efficiency at 100 deg. Fah.} = 100 - \frac{796 \times 100}{43{,}596 + 42{,}800}$$
$$= 100 - 0{\cdot}92$$
$$= 99{\cdot}08 \text{ per cent.}$$

Net gear tooth and bearing efficiency at 65 deg. Fah.

$$= 100 - \frac{228 \times 100}{43{,}128 + 42{,}800}$$
$$= 100 - 0{\cdot}27$$
$$= 99{\cdot}73 \text{ per cent.}$$

The probable accuracy of the results given above may be analysed as follows :—

Accuracy of measurement of pinion torque arm radius	$= \pm\frac{1}{8}$in. = 0·2 per cent. on total torque
Accuracy of measurement of applied weights	= ±2 lb. = 0·3 per cent.
Possible error due to friction in coupling spigot and mis-alignment in drilling couplings	= 2·0 per cent.
Possible total error in pinion torque..	= 2·5 per cent.
Possible error of observation of spring balance	= ±0·25 lb.
Possible error in taking difference ..	= 0·5 lb.
Possible error in driving torque ..	= 0·5 × 34·5 lb. in. = 17 lb. in.

Since the full load loss is only about 1 per cent., the possible error in pinion torque represents only 0·025 of 1 per cent. The percentage error in efficiency value due to error of observation of the spring balance is 17 × 100/85,600 = 0·02 of 1 per cent.; hence the probable error of the efficiency values will be less than 0·05 of 1 per cent.

Acknowledgments are due to David Brown and Sons (Huddersfield), Ltd., for permission to publish these results.

INSTITUTION OF ELECTRICAL ENGINEERS.

THE following scholarships have been awarded by the Institution of Electrical Engineers for 1933 :—

Duddell Scholarship (Annual value, £150 ; tenable for three years).—H. Haywood (Staveley Grammar School).

Silvanus Thompson Scholarship (Annual value, £100, plus tuition fees ; tenable for two years).—P. L. Olsen (C. A. Parsons and Co., Ltd.).

Swan Memorial Scholarship (Annual value, £120 ; tenable for one year).—D. A. Bell, B.A. (Magdalen College, Oxford).

David Hughes Scholarship (Value, £100 ; tenable for one year).—R. C. Barton (University College, Cardiff).

Salomons Scholarship (Value, £100 ; tenable for one year).—R. S. Quick (Bristol University).

War Thanksgiving Education and Research Fund (No. 1).—Grants of £50 each to R. G. Armstrong (University College, London), D. H. R. Whyman (Sheffield University).

Paul Scholarship (Annual value, £50 ; tenable for two years).—R. P. Kinsey (Wandsworth Technical Institute).

Thorrowgood Scholarship (Annual value, £25 ; tenable for two years).—L. F. Tuff (London and North-Eastern Railway).

NOTE.—No award of the Ferranti Scholarship was made this year.

LAUNCHES AND TRIAL TRIPS.

AAGTEKERK, twin-screw motor ship ; built by the Netherland Shipbuilding Company, to the order of Messrs. N. V. Vereenigde Nederlandsche Scheepvaartmaatsch appij ; dimensions, 493ft. by 60ft. by 40ft.; to carry passengers and cargo. Oil engines, of "Stork-A.E.G.-Hesselman" type ; constructed by Messrs. Stork and Co., of Hengelo ; launch, October 7th.

ISIPINGO, motor vessel ; built by Workman, Clark and Co., Ltd., to the order of Messrs. Andrew Weir and Co ; dimensions, 425ft. by 57ft. by 37ft.; to carry passengers and cargo. Oil engines, of Workman Clark-Sulzer Diesel type ; constructed by the builders ; launch October 9th.

BEN HENSHAW, motor tanker ; built by Rowhedge Ironworks Company, Ltd.; to the order of National Benzole Company. Ltd.; dimensions, 135ft. by 25ft. by 12ft.; to carry oil in bulk, Oil engines, twin 5 J 8 Gardner type ; trial trip, October 13th.

CONTRACTS.

MELDRUMS, Ltd., Timperley, have received the order to fit their patent sprinkler stokers to seven boilers at the Prestwich Mental Hospital.

RADIOVISOR PARENT, Ltd., 28, Little Russell-street, W.C.1, has received an order for equipping the power station of the Wimbledon Corporation with its industrial smoke indicator.

FRANK HOW AND CO., Ltd., of Stratford, have been accorded the whole of the contract for the Egyptian Delta Light Railways. They have also received a further order for 10,000 gallons of cylinder oils from the Egyptian State Railways.

RICHARD DUNSTON, Ltd., of Thorne, Yorkshire, has received notification from the War Office of the acceptance of its tender for a single-screw Diesel-engined steel vessel, with dimensions 85ft. by 17½ft. by 7ft. The propelling machinery will consist of a 120 H.P. "Mirrlees" engine, complete with the necessary auxiliaries.

THE L.N.E.R. reports that the undermentioned contracts have been placed :—Mitchell Conveyor and Transport Company, Ltd., for modifications to the feeder apparatus of the coaling plant at Hornsey locomotive depôt ; Cowans, Sheldon and Co., Ltd., for twelve 30-cwt. electric capstans and thirty-one fairleads to be installed at Parkeston Quay, Harwich ; Horseley Bridge and Engineering Company, Ltd., for a water-softening plant at Retford, to deal with 7500 gallons per hour ; and the Butterley Company, Ltd., for steelwork for an overbridge between Yaxley and Peterborough.

PERSONAL AND BUSINESS ANNOUNCEMENTS.

GENT AND CO., Ltd., have removed their branch office at Newcastle-on-Tyne from Blackett-street to "Tangent House," Leazes Park-road, Newcastle-on-Tyne, 2.

COCHRANES (MIDDLESBRO'), Ltd., have opened an office in London at 11, Arundel-street, Strand, W.C.2, and have appointed Mr. E. M. Gill to be sales representative in London and the South.

BRITISH ARCA REGULATORS, Ltd., have just moved to the fourth floor of Windsor House, Victoria-street, London, S.W.1. The postal address remains as before, and the telephone numbers are Victoria 2275 and 7456.

RAILWAY AXLE PLANT FOR RUSSIA.—In the description of a "Railway Axle Plant for Russia," contained in our issue of October 6th last, it was stated that the plant was designed to give an output of 270,000 axles per annum. This is not correct. It should have been stated that the plant forms part of a scheme for the production of this number of axles.

A RECORD OF LONG SERVICE.—It is the custom of Glenfield and Kennedy, Ltd., Kilmarnock, to present a gold medal to each of their members of staff and employees on the attainment of fifty years' continuous service with the firm. Mr. W. W. Muir, buyer, is the latest member who has qualified for this distinction, bringing the number of medals presented during the last four years up to twenty-six.

INGENIEURS CIVILS : BRITISH SECTION.—The following gentlemen have been elected for the session 1933–1934 as the Council of the British Section of the Société des Ingénieurs Civils de France :—President : W. R. Howard, M.I. Struct. E. Vice-Presidents : H. K. Scott, M. Inst. M.M.; R. H. Stanger, A.M. Inst. C.E. Members : W. J. E. Binnie, W. T. Halcrow, M. Inst. C.E., Sir Geo. Humphreys, Sir Henry Japp, H. A. Reed, M. Inst. C.E., Gilbert Szlumper. Honorary Treasurer : T. J. Gueritte. Honorary Secretary : A. Kirkwood Dodds, M.I. Struct. E.

SCHOLARSHIPS.—The North-East Coast Institution of Engineers and Shipbuilders has made the following awards :—Institution Scholarship, value £100 per annum, to William Leslie Stewart ; grant of £50 to John Campbell Matthew. George Mitchell Harroway Scholarship, value £100 per annum, to Guy Gowland Harforth. In addition to the above awards, the Scholarships of Mr. E. J. C. Statham (1931 scholar), and Mr. John Cecil Brown (1932 scholar) have been continued for a further year. The total value of the above scholarships and grants awarded by the Institution is £450.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

The Import and Export Figures.

The Board of Trade returns for September show that the British iron and steel trades have maintained their position. Comparing the volume of business during the first nine months of the current year with that of 1931 and 1932 there has been a decrease in the imports and an increase in exports. The imports of pig iron, if we except the arrivals from India, were so small that the monthly totals have little importance. For the first nine months of the year the imports of forge and foundry iron were only 27,591 tons, of which 20,000 tons came from India. The total imports of basic iron to the end of September was 40,333 tons, of which all but 30 tons came from India. The imports of blooms and billets during September reached 24,871 tons, compared with 27,324 tons in September, 1932, and 41,590 tons in September, 1931. Imports of girders, beams, and joists from the Continent are slightly in excess of last year, and for the first nine months total 58,936 tons against 53,148 tons for the same period of 1932, but show a distinct reduction when compared with the 1931 figures of 74,767 tons. The imports of plates and sheets for the nine months dropped to 30,233 tons, compared with 60,509 tons last year, whilst 52,000 tons of hoop and strip were brought in against 85,410 tons in 1932. On the export side, pig iron shows a decline from 89,641 tons for the first nine months of 1932 to 75,601 tons this year. Bars, rods, angles, and sections are fairly consistent at 4711 tons for the nine months, against 4984 tons last year. Exports of plates and sheets also are down, the total for the nine months being 56,611 tons, whilst for the same period last year the figure was 85,560 tons. On the other hand, plates and sheets, under ⅛in. thick, have improved to 95,825 tons, against 84,293 tons for the nine months in 1932. The exports of galvanised sheets, however, are not so good, the total being 187,214 tons for the nine months ended September 30th, compared with 215,104 tons for the same period of 1932. Tubes, cast and wrought, show an improvement, whilst the exports of new steel rails are up to 52,676 tons, compared with 32,505 tons last year. Other classes of railway material also show an improvement.

Machinery Exports.

Although the exports of machinery show a decline in value over the nine months ending September 30th this year compared with the corresponding period in the two previous years, the figures for September show an increase. For the nine months the total value was £19,771,229, compared with £22,654,449 last year. On the other hand, the value of the September machinery exports was £2,306,437, compared with £1,881,549 in 1932. The value of the export trade in prime movers totalled £216,299, compared with £161,626 in the corresponding month of last year. Of this total British South Africa took £31,071, and European countries £21,727; Australia taking machinery to the value of £14,151. The export of machine tools was valued at £88,000, of which Soviet Russia was the largest buyer, taking £42,317, British India being next at £9856. In September last year the exports were valued at £193,000, but the difference is largely accounted for by the fact that in that month exports to Russia were valued at £134,841. Agricultural machinery to the value of £50,787 was exported in September against £37,181 in September, 1932. The exports of textile machinery also showed an improvement to £385,077, against £364,863 in September of last year.

The Continental Steel Position.

The iron and steel markets of the world are not so easily affected by political influences as are some commodity markets, and there are good grounds for believing that, notwithstanding the disturbances created in international politics by Germany's withdrawal from the League, the steel trade will not be much upset. To some extent the Continental industries will feel the re-percussion of political events, but this is largely because they have Cartelised the principal European trades so that anything which affects, for instance, Germany, must also affect France, Belgium, and Luxemburg, and *vice versâ*. At the present moment it is probable that the industries are not likely to be worse off, since for months past they have been existing on a hand-to-mouth flow of orders. Recently, a number of meetings have been held at which efforts have been made to smooth out some of the more obvious difficulties in the way of reconciling the merchants to the steel makers' methods of selling through comptoirs, but apparently little success has attended their endeavours. The Belgian industry has been in a worse position then either the French or German, but these latter appear to be now threatened with conditions almost as bad. It is reported that the Cartel has now to meet claims from the French and German steel makers for larger shares of the orders received, and as the Belgian industry is equally pressing, a difficult situation has arisen.

Conditions in America.

The prospect of competition from the American steel works in the export markets must be causing lively apprehension to the Continental manufacturers; but, for the time being, the Americans seem too preoccupied with affairs in their domestic market to set out to capture export trade. The first flush of buying which followed America's departure from the gold standard and the adoption of President Roosevelt's recovery plan has passed; but if the American steel trade did not benefit as much as some American industries, at least it appears to have maintained most of the ground it then gained. The steel "code," however, has not so far fulfilled expectations. It has certainly eliminated speculative buying, and to this is attributed the reduction in the United States Steel Corporation's unfilled orders at the end of September by 114,704 tons to 1,775,740 tons, which is the lowest figure on record. Another disappointment to the steel trade has been the absence of railway buying. It was understood when the code was entered upon that the Government would assist the railway companies to place long-awaited orders for rails. It now transpires that although the Government is willing to assist the railways financially, the latter decline to place orders unless prices are reduced. The steel makers retort that their costs and wages are increasing, and that they can scarcely afford to sell even at current prices, and there the matter rests.

Iron and Steel Production.

The monthly figures for iron and steel production issued by the National Federation of Iron and Steel Manufacturers show that outputs were maintained during September. At the end of the month seventy-four furnaces were in blast, an increase of one since the end of August, two having been blown in and one having ceased operations. Although it is not stated in the Federation's report one of the furnaces was started up on hematite at the Millom and Askam Hematite Iron Company's works, and the other on basic iron by Dorman, Long and Co. The furnace put out of commission belonged to the New Cransley Iron and Steel Company, in Northamptonshire. The production of pig iron in September amounted to 359,700 tons, compared with 362,700 tons in August (a slightly increased daily rate), and 260,400 tons in September, 1932. The production includes 118,400 tons of hematite, 150,600 tons of basic, 75,200 tons of foundry, and 8100 tons of forge pig iron. The output of steel ingots and castings in September amounted to 669,000 tons, compared with 551,300 tons in August and 430,300 tons in September, 1932.

Pig Iron.

The slight irregularity in trading which is noticeable in the pig iron market is principally due to the circumstance that most users are covered for some time ahead. In some cases they have bought for delivery well into next year. For the time being, therefore, dealings are chiefly confined to small parcels; but users show little inclination to delay placing even small orders as they are evidently nervous regarding the possibility of an increase in prices. There is, however, a difference of opinion as to the likelihood of prices being raised except in the case of hematite. Although production costs have advanced stocks in several districts are still heavy, and any substantial upward movement might be followed by an increase in the importation of foreign iron. The quantities of Indian basic and foundry iron imported are regulated by an agreement between the British and Indian producers; but heavy stocks of foundry and basic exist on the Continent, and there is little doubt that the holders would welcome an opportunity of disposing of some of these accumulations at cheap prices in the British market. Perhaps the most favourably situated district in this country is the North-East Coast. The production of Cleveland iron is still limited to two furnaces, and, according to all accounts, little unsold iron is left in the makers' hands. Lately there have been hints that the stocks have not been reduced to the extent reported, and it is a pity that the producers cannot see their way to issue a statement on the position. One argument used against the view that stocks have been dispersed is that the makers continue to quote for export at much below their official home prices. It is intended to start up another furnace towards the end of the month at Dorman, Long and Co.'s Cleveland works. There is a prospect also that some of the coke batteries on the North-East Coast will be restarted and ironstone mines reopened. In the Midlands buying does not seem to be quite so brisk as of late, but the demand is said to be equal, if not in excess of, production. Hematite prices are steadily strengthening and have advanced to £3 0s. 6d. for No. 1, and £3 for mixed numbers.

Semi-finished Steel.

An interesting situation is developing in the market for semi-finished steel materials. The excellent position in which the British producers of billets and sheet bars find themselves, owing to the diversion of orders from the Continent as a result of the application of import duties, is leading to a gradual stiffening in price. Many consumers have entered into arrangements with suppliers, the most outstanding instance being that between the Whitehead Iron and Steel Company, Ltd., and Richard Thomas and Co., Ltd., by which the latter supply the former with the necessary raw material from their Redbourn Hill Works. In some respects it is unfortunate that the figures of production for this class of material are not obtainable, as they would probably disclose a very large increase in output during the last few months. Many of the makers are unable to give delivery before the end of the year, whilst others are asking premiums of from 5s. to 7s. 6d. One of the results of these rather tight conditions is that somewhat heavier purchases of Continental semis have taken place during the past few weeks than for several months. Sellers of this material claim that where it is required for special purposes they have been able to obtain higher prices than those asked by the British makers; but that for ordinary work the prices quoted have been subject to negotiation and have been well below the British price after the duties have been paid. It will be interesting to see if the trade in Continental semis will continue to increase, although, of course, it can never reach the proportions of pre-duty days. A comparison of the tonnage imported to the end of September this year with the imports for the corresponding periods of previous years is interesting. In 1931 the total for the nine months was 825,546 tons; in 1932 it fell to 633,253 tons, and in this it is down to 220,638 tons.

Finished Steel.

Although some departments of the finished steel branch of the industry have become less active during the past week or two, on the whole the gains have exceeded the losses. The completion of the Argentine orders for galvanised sheets has left the makers short of work, and they are pressing for new business. The demand for boiler plates also remains at a disappointing level, whilst most branches of the trade dependent upon shipbuilding are feeling the ill-effects of the slump in this department. On the other hand, the production of plates, ⅛in. and over, has been on a good scale, the figures for the past few months showing a substantial increase over the average monthly rate for the last two years. The output of sections, girders, and joists also is considerably in excess of the averages for 1931 and 1932, the figure for last July being 128,400 tons, and it is probable that this rate was maintained in August and September. On the North-East Coast steel is being produced at the rate of over 100,000 tons per month, and there seems a likelihood that this rate will be increased. The constructional engineering shops in this district are well off for work, and a fair amount of business in the way of orders for rails is also in hand. In the Midlands there has been some falling off in the demand for finished steel, some of the structural engineering companies having worked off several fair-sized contracts to replace which fresh orders are required. On the other hand, business in black sheets has expanded. The Midland re-rollers also are well employed on contracts for steel bars booked a few weeks ago, but at the moment there is not a great deal of new business passing. Some transactions in Continental material have been heard of, but considering that the price of the British small bars is now £6 17s. 6d., whilst the Continent continues to quote in the neighbourhood of £6 10s., it is almost surprising that more orders are not going abroad.

Scotland and the North.

Steady, rather than active, conditions have ruled in the Scottish market for the past fortnight. The production of finished steel is below capacity, but this year there have been one or two intervals of quietness which have been followed by an increased demand. The placing of an order on the Clyde for a naval sloop of 1500 tons will provide some business for the steel makers, although there seems no immediate likelihood of the shipbuilding industry escaping from the depression which has affected it for so long. William Beardmore and Co., Ltd., have booked an order for forgings which will be used in the construction of Imperial Chemical Industries' new plant for extracting oil from coal. The Scottish re-rollers are not so busy as the English branch of the industry. They have maintained their price for home delivery at £7 5s. and £6 15s. for export, f.o.b. Glasgow. Continental sellers quote similar material at much less and are taking a certain amount of business. In the Lancashire market there is a fair demand for constructional steel, but it is made up of small orders. The demand for special alloy products, however, and for bright steel bars continues active, and business in strip remains on a good scale. For the moment the volume of inquiry has fallen off, but it is regarded as only a temporary lull. The works on the North-West Coast have resumed operations after the stoppage of a week at Workington. They are principally engaged upon rolling railway material, whilst at Barrow the finishing departments are producing bars and hoops. In South Wales new business in tin-plates has been rather quieter, but this is not an unusual feature at this season, and the works are well employed, operating at about 66 per cent. of capacity. Even in this comparatively dull period orders are coming to hand sufficient almost to equal those which are being completed.

Copper and Tin.

A feature of the copper market this week has been the resistance shown to the depressing effects of the international political crisis. This market is usually over-sensitive if anything to outside influences, and the fact that prices have been firm rather than weak indicates that the undertone of the market is sound. The fall in values which took place last week had, of course, made the metal undeniably cheap, and there may have been a certain amount of buying by Continental interests who fancied copper as a safe lock-up in difficult times. Buying for industrial purposes has been poor, and consumers seem determined to adhere to their policy of covering only for their immediate requirements. Business in manufactured copper materials has not been good, and this, combined with the recent weak tendency of prices of the raw metal, has no doubt encouraged consumers to postpone purchases as long as possible. Prices in the London standard market have shown a tendency to move in sympathy with the electrolytic quotations. The stocks of copper are decreasing, and although some metal has been imported from the Continent, the tonnage is not sufficient to make up for the withdrawals from warehouse. . . . The tin market also has not been greatly influenced by the unfavourable political situation. The slight reaction in prices which occurred early in the week was short-lived, and a firmer tone afterwards developed. Most of the bull accounts in this market seem to have been liquidated, but whenever prices have looked like receding support has been forthcoming from powerful interests which, not unnaturally, the market assumes to be connected with the Pool. Buying from the United States and the Continent has been light, and the South Wales tin-plate makers have not shown much interest in the market. Statistically, however, the position appears to be gathering strength and a decline of as much as 3000 tons is anticipated in the visible supply at the end of October.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

Engineers and Architects.

In the designing of residential buildings the architect was formerly able to follow more or less orthodox lines and prepare his plans and execute them with the certainty that they would not be subjected to criticism. The last decade has witnessed an entire change in the character of those buildings, which must be designed with a view to "modern comfort," comprising bathrooms, central heating, and electrical equipment, and the scientific application of hygienic principles has introduced factors of lighting and insulation from heat and cold, while new building materials have necessitated far more care and supervision than in the days when houses were built of stone. The profession of the architect therefore encroaches upon the domain of the engineer, and even if he were able to acquire a full knowledge of all these new factors in building, the architect would still find it difficult to survey everything and guarantee that the work will be permanently satisfactory. The architect has to rely upon the contractor and upon the suppliers of installations and fittings. It is complained that his specifications are not sufficiently detailed, and that the wide range of tenders for the work can only be explained by different interpretations of the specifications, with the result that the lowest tenders are not necessarily the cheapest. It is therefore suggested that architects should have the assistance of engineers, who will prepare specifications, particularly with regard to heating, electrical, and other apartment fittings which must provide for future developments in the way of domestic utilisation. The engineers would also survey the execution of the mechanical and electrical work instead of leaving it to the contractor. The engineer would provide a guarantee of security.

The Forty Hours' Week.

A condition attached to the programme of public works is that the forty hours' working week will be imposed in all cases, and that it must be observed by firms supplying material purchased by the State for those undertakings. This stipulation is naturally causing a good deal of uneasiness amongst manufacturers, who can hardly employ men specially on such orders without making the observance of the forty hours' week general in the shops where the work is being executed. Manufacturers are unanimous in their objection to follow the Government in its policy to secure international recognition of the short week, and while the effects on costs produced by the forty hours' week without wages reduction are supposed to fall equally on makers in all countries if the system is adopted internationally, it cannot be applied solely to France without putting industry entirely out of the running in competition for world trade. Already industry in this country is so heavily burdened by taxation and social charges that manufacturers insist upon immediate relief in order to avoid succumbing to the tide of rising costs. They fear that the stipulation proposed to be attached to orders for public relief works will be the thin end of the wedge which will eventually make the forty hours' week more general.

Conservatoire des Arts et Metiers.

In view of the increasing number of students applying for admission to the Conservatoire des Arts et Métiers it was found necessary to provide additional accommodation, which offered difficulties because the building cannot be extended in area or in height. The school forms part of the Priory of Saint-Martin-des-Champs, which was built in the eleventh century, and the Conservatoire des Arts et Métiers was installed in it at the time of the French Revolution. The only way of providing new class rooms was to build them under the courtyard, which has, on one side, the part of the Priory used as a library, and the work had to be carried out without risk of weakening the foundations of that historic building. Concrete piers were constructed underground and upon them was laid a reinforced concrete platform, after which the excavation was continued to a depth of 18 m. and three lecture halls were constructed, providing a total accommodation for 1300 students. The work has now been completed, and the underground lecture halls will be inaugurated shortly by the President of the Republic.

The Vosges Tunnel.

Eight months ago work was started upon the tunnel through the Vosges between Saint-Maurice and Wisserling in order to connect up the Est and Alsace-Lorraine railways and shorten the distance between Calais and Switzerland by 32½ miles. The time thus employed included that spent on preliminary works, and tunnelling has so far only advanced 500 m. Operations are seriously retarded by the number of springs that are being tapped, producing at times as much as 1800 litres per minute. Arrangements will have to be made to drain off permanently what is likely to be a large volume of water. The length of the tunnel will be 5¼ miles, the width 9·5 m., and the height above the permanent way 6·1 m. It will have a constant gradient of 8 mm. per metre. Owing to the difficulties encountered it is expected that it will take five years to complete the undertaking.

The Steel Cartel.

The working of the International Steel Union was dependent on the Belgian group being able to secure the support of the Forges et Clabecq, which had persistently held aloof from the negotiations and finally consented to join up temporarily with a view to seeing whether the operations of the Cartel would be favourable to its interests. At the recent annual meeting of the Forges et Clabecq the managing director stated that the company was dissatisfied with the result of its participation in the work of the Union and that, unless the situation improved, it would be obliged to withdraw from the Cartel at the end of the year.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office, Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

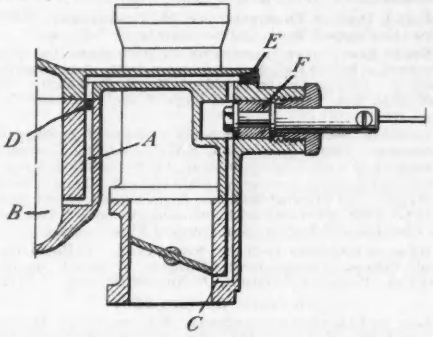
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

INTERNAL COMBUSTION ENGINES.

397,991. June 4th, 1932.—Carburetters, C. H. L. Wynne, E. W. Knott, and A. C. Miller, of Bendix-Perrot Brakes, Ltd., King's-road, Tyseley, Birmingham.

The object of this invention is to facilitate the starting up of a petrol engine by supplying it, for the time being, with a comparatively rich mixture. A passage A leads from the float chamber B of the carburetter to the port C on the engine side of the throttle valve. In this passage there is arranged an orifice D, which is of such a size that it will pass sufficient petrol to run the engine at a speed slightly in excess of its normal idling speed until it is warmed up enough to take up the load. There is also an opening to atmosphere at E, through which air is sucked to gasify the fuel. A piston valve F is provided to shut off the passage. For starting up the throttle is closed and the piston valve opened, and when the engine is running properly the piston valve is closed.—*September 7th*, 1933.

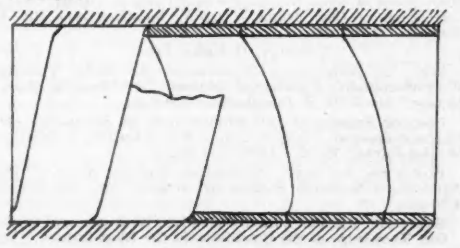
Nº 397,991



398,009. July 18th, 1932.—Cylinder Liners, Gebr. Lüttges, Kom. Ges. (sole responsible partner Gustav Lüttges), Solingen, Rheinland, Germany.

The inventor explains, at considerable length, the troubles which may be experienced when the cylinder of an internal combustion engine is provided with a rolled steel liner, and goes on to claim that these troubles will be overcome if the liner is formed as a helix, as shown in the drawing. It is inserted in the cylinder bore with a twisting action, so that when it is released it expands tightly against the bore.—*September 7th*, 1933.

Nº 398,009



SWITCHGEAR.

398,075. December 30th, 1932.—Electric Liquid-break Switches, *The British Thomson-Houston Company, Ltd., of Crown House, Aldwych, W.C.2.*

The invention relates to liquid-break electric switches having arc-extinguishing or explosion chambers in which the contacts separate. The invention is particularly concerned with explosion chamber switches in which the chamber also forms a container for the liquid, and is installed in the open, and is, consequently, subjected to the influences of the atmosphere. The extinguishing chamber consists of an inner cylinder A of hard paper and a ceramic outer insulator B of the customary ribbed type. The bottom C carries the fixed contact D, whilst the movable contact rod E is guided by the hood F on which a fixed contact G may be provided. Both the bottom C and the hood F are rigidly connected with the insulating body A. The pressure set up on switching is taken up exclusively by the internal insulator A. The external insulator B is connected with the switching chamber at its upper end by means of the elastic corrugated tube H through the hood F, which may, if necessary, be elastic. The lower connection J of the external insulator with the switching chamber may also be elastic. The connections should preferably be such as to exclude atmospheric changes from affecting the space between the two insulators. With a view to easier mounting and interchangeability, the elastic intermediate element H or J may be disengageably connected to flanged rings K cemented to the insulator B, whilst it has a welded or soldered connection at its other end. The extinguishing chamber may be filled either with a conducting liquid, such as water, or with an insulating liquid, such as oil.—*September 7th*, 1933.

TRANSFORMERS AND CONVERTERS.

397,856. November 21st, 1931.—Transformers of the Static Type, Hugh Godfrey Nicholson, of Britannia Works, Colchester.

The main object of this invention is to provide a transformer, the secondary voltage of which will keep constant or will increase at a predetermined rate with increasing lead current. As shown in Fig. 1, a laminated magnetic circuit A links the turns of the primary B, but not the turns of the secondary C, the auxiliary magnetic being outside the window D of the transformer. Additional control may be obtained by the addition of a coil E connected in series with a variable condenser F, as shown in Fig. 2. Another alternative scheme is described and the theory is explained in each case.—*August 21st*, 1933.

Nº 397,856

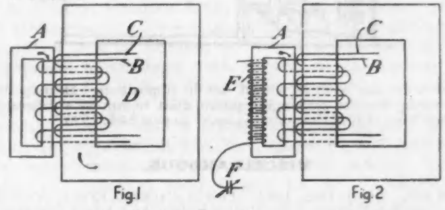

Fig. 1 Fig. 2

397,953. April 6th, 1932.—Protective Arrangements for Electric Power Transformers, The General Electric Company, Ltd., of Magnet House, Kingsway, London, W.C.2: and Charles Cornfield Garrard, of the General Electric Company, Ltd., Engineering Works, Witton, Birmingham.

A protective arrangement for an electric power transformer, according to this invention, comprises a switch or circuit breaker with or without fuses on one side of the transformer, a switch fuse on the other side of the transformer and a removable mechanical operating or interlock device which must be positioned relatively to the switch or circuit breaker before the latter can be closed and relatively to the switch fuse before the latter can be opened. Means are also provided for preventing removal of the device from the switch or circuit breaker unless the latter is open and means for preventing removal of the device from the switch fuse unless the latter is closed. The transformer is provided with a high-tension winding delta connected to the three phases of the supply through individual phase switch fuses A. The low-tension side of the transformer is delta connected through a circuit breaker B to the low-tension lines. Referring now to Fig. 2, the three switch fuses are provided with a common operating spindle C extending through the wall of the switch fuse enclosure D. The spindle C is formed with a square head for a removable operating handle E provided with an axial extension piece F. If the operating handle is moved to the "off" position, wherein the switch fuses are opened, the extension piece F moves between a lug G mounted on the wall of the enclosure D and the wall itself, and accordingly prevents removal of the operating handle E, which can therefore only be removed when it is in the "on" position, *i.e.*, when the switch fuses A are closed. The low-tension circuit breaker B is also provided with a common operating shaft H—Fig. 3—which extends through the wall of the circuit breaker enclosure J and is formed with a square head which is adapted to be engaged by the operating handle E. In this case it is arranged that when the operating handle is in the "on" position, *i.e.*, the circuit breakers are closed, the axial extension K of the operating handle is between a lug L formed or mounted on the wall of the enclosure J and the wall, so that the operating handle cannot be removed when the low-tension circuit breaker B is in the closed position, but only when the breaker is open. Since only one handle E is provided for the operation of both the high-tension switch fuses A and the low-tension circuit breaker B, the switch fuses can be opened or closed only when the circuit breaker B is open.—*September 7th*, 1933.

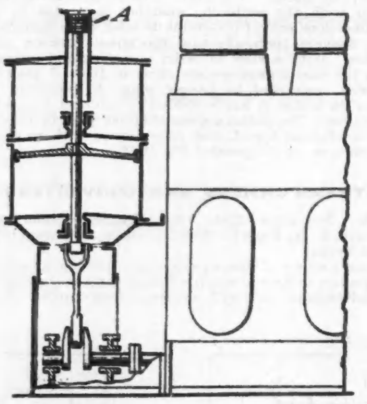
TRANSMISSION OF POWER.

397,387. February 14th, 1933.—Balancing Reciprocating Engines, Sulzer Freres Société Anonyme, Winterthur, Switzerland.

Cyclic variations in the speed of the crank shaft of, for instance, a multi-cylinder oil engine are, according to this invention, minimised by placing a weight A on an extension of the scavenging pump piston rod. The pump crank is then set in such a position that the impulses from the working cylinders and from the balance weight act in opposition. It may be necessary for the scavenging pump shaft to run at a different speed from that of the main engine.—*August 24th*, 1933.

No. 397,387

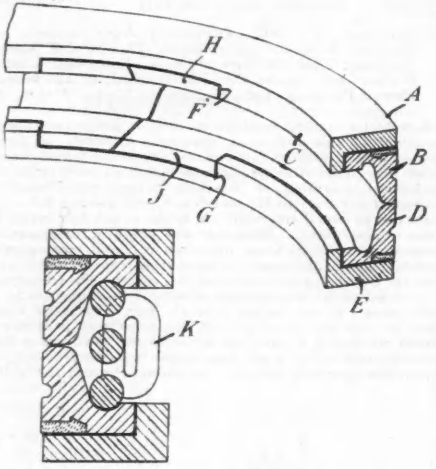


MISCELLANEOUS.

396,854. March 18th, 1932.—Piston Packing Rings, Wilfred Stephen Carlisle, John Robert Kelsey, and Albert Corbidge, all of Eagle Foundry, Stalker Lees-road, Sheffield.

The piston ring comprises a complete or undivided ring A of similar diameter to the packing rings B, D, and having a flange or lip C on its inner side, which is placed over the packing ring B with its flange or lip C downwards. A similar ring E is placed under the lower packing ring D with its flange upwards. Each of these rings A, E has a portion of its lip or flange cut away, as shown at F, G, and a segmental extension H, J on each of the split packing rings fits into these cut-away portions. A double-acting spring packing ring K is placed between the two split packing rings.—*August 17th*, 1933.

No. 396,854



397,992. June 7th, 1932.—Devices for Propelling by Reaction, J. A. Rey, 30, Rue de Versailles, Viroflay (Seine-et-Oise), France.

This invention is put forward as a means of propelling ships, road vehicles, or aircraft by an ejector action. It is suggested that steam should be used as the propelling medium and that it should be first used to entrain air and then the mixture of steam and air used to entrain, for instance, sea water for the propulsion of a ship. In which case it is said, the boiler may be fed with sea water. The inventor gives some calculations to substantiate the efficacy of his arrangement and insists that it must comprise " a duct for the passage of propelling fluid having an enlarging taper formed from a single body of material and provided with a succession of ports for the progressive entrainment of additional fluid by injector action, the outlet being of substantially constant cross section so as to maintain constant the speed of the issuing fluids."—*September 7th*, 1933.

Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the* TIME *and* PLACE *at which the meeting is to be held should be clearly stated.

To-day.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. Informal meeting; election of Sub-committee. Discussion, "The Horse-power of Locomotives," introduced by Mr. A. G. Hopkins. 7 p.m.

Inst. of Sanitary Engineers.—At Caxton Hall, Westminster, S.W.1. "Aggregates for Concrete Work," Dr. Bernard H. Knight. 6 p.m.

Inst. of Structural Engineers: Scottish.—129, Bath-street, Glasgow. Chairman's address, Professor Sir Thomas Hudson Beare. 7.30 p.m.

Inst. of Structural Engineers: Western Counties.—Merchant Venturers' Technical College, Unity-street, Bristol. "Foundations," Mr. G. B. R. Pimm. 7.15 p.m.

Junior Inst. of Engineers.—At 39, Victoria-street, S.W.1. "Air Lift Pumps," Mr. A. C. Judd (member). 7.30 p.m.

North-East Coast Institution of Engineers and Shipbuilders.—Bolbec Hall, Newcastle-upon-Tyne. Annual general meeting. Address by the President, Mr. R. J. Walker; cinematograph film, "Mechanism of Ships' Wake,' Professor T. B. Abell.

Physical Society.—At Imperial College of Science and Technology, South Kensington, S.W.7. Editing Committee meeting, 3.30 p.m.; Council meeting, 4 p.m.; meeting, 5 p.m.

Soc. of Chemical Industry (Food Group).—London School of Hygiene and Tropical Medicine, Keppel-street, Gower-street, W.C.1. Joint discussion with Physiological Soc., "Diet from the Chemical and Physiological Points of View." 8 p.m.

West of Scotland Iron and Steel Inst.—At Royal Technical College, George-street, Glasgow. Council meeting, 6.45 p.m. Presidential address, Dr. Andrew McCance. 7.15 p.m.

Saturday, October 21st.

Inst. of Electrical Engineers: N.E. Students' Section.—Visit to Messrs. A. Reyrolle and Co.'s short-circuit test plant, Hebburn. 2.30 p.m.

Inst. of Electrical Engineers: North Midland Students.—Visit to works, A. Kershaw and Sons, Ltd., Harehills-lane, Leeds. Meet G.P.O., City-square, Leeds, 2.30 p.m.

Inst. of Electrical Engineers: S. Midland Students.—Afternoon visit to *Birmingham Gazette*, Ltd., offices, Corporation-street, Birmingham.

Inst. of Mechanical Engineers: Graduates.—Visit to the de Havilland Aircraft Company, Stag-lane Aerodrome, Edgware.

N. of England Inst. of Mining and Mechanical Engineers.—Newcastle-upon-Tyne. Presidential address, Mr. W. R. Glass. Paper, "Microstructure of the Coal of Certain Fossil Tree Barks," Professor G. Hickling and Mr. C. E. Marshall. Discussions: "Impoverished Areas of the Maudlin and Busty Seams in the Durham Coalfield," Dr. William Hopkins; "The Microspores of some Northumberland Coals and their Use in Correlation of Coal Seams," Dr. A. Raistrick and Mr. J. Simpson. 2.30 p.m.

Tuesday, October 24th.

Inst. of Automobile Engineers.—At Hotel Victoria, Wolverhampton. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7.30 p.m.

Inst. of Engineers and Shipbuilders in Scotland.—39, Elmbank-crescent, Glasgow, C.2. "Flame Cutting of Steel for Welded Joints," Mr. E. J. Clarke. 7.30 p.m.

Royal Soc. of Arts.—John-street, Adelphi, W.C.2. "The Agricultural Research Station at Amani," Mr. W. Nowell. 4.30 p.m.

Sheffield Metallurgical Soc.—198, West-street, Sheffield. "Our Knowledge of the Conditions in the Blast-furnace," Mr. R. C. Tucker. 7.30 p.m.

Societe des Ingenieurs Civils de France: British Section.—At Inst. of Civil Engineers, Great George-street, S.W.1. "New Methods of Excavating Quicksands and Unstable Ground," Sir Henry Japp. 6 p.m.

Wednesday, October 25th.

Inst. of Mechanical Engineers: Yorkshire.—Grand Hotel, Sheffield. "Fatigue and Corrosion Fatigue, with Special Reference to Service Breakages," Prof. Frederic Bacon. 7.30 p.m.

North-East Coast Inst. of Engineers and Shipbuilders: Graduate Section.—"Electric Cargo Winches," Mr. C. E. Clouston. 7.15 p.m.

Thursday, October 26th.

Glasgow University Engineering Soc.—At James Watt Engineering Laboratories, University. Presidential address by Mr. H. A. Reincke. 7.30 p.m.

Inst. of British Foundrymen.—Joint meeting with Midland Metallurgical Societies at James Watt Memorial Inst., Birmingham. Discussion, "The Production of Sound Iron Castings." 7.30 p.m.

Inst. of Electrical Engineers.—Savoy-place, W.C.2. Presentation of Premiums. Presidential address, Mr. P. V. Hunter. 6 p.m.

Inst. of Locomotive Engineers.—At Inst. of Mechanical Engineers, Storey's-gate, S.W.1. "Some Aspects of the Organisation and Operation of a Colonial Railway Running Department," Mr. J. G. B. Sams. 6 p.m.

Inst. of Mechanical Engineers.—At Dorchester Hotel, Park-lane, W.1. Annual dinner, 6.45 for 7.15 p.m.

Inst. of Mechanical Engineers: Yorkshire.—Queen's Hotel, Leeds. "Fatigue and Corrosion Fatigue, with Special Reference to Service Breakages," Prof. Frederic Bacon. 7.30 p.m.

Inst. of Structural Engineers.—10, Upper Belgrave-street, S.W.1. "The Cumberland Hotel and Annexe," Mr. A. Frost. 6. 30 p.m.

University of London.—King's College, Strand, W.C.2. Department of Mechanical Engineering. "Injection and Combustion in High-speed Oil Engines: ii., Basic Problems—Cycle of Reference—Utilisation of Air," Dr. S. J. Davies. 5.30 p.m.

Friday, October 27th.

Inst. of Chemical Engineers.—At Inst. of Civil Engineers, Great George-street, S.W.1. "Engineering in the Service of Chemical Research," Professor G. T. Morgan. 6.30 p.m.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. General meeting. Presidential address, Mr. Alan E. L. Chorlton. 6 p.m.

Inst. of Structural Engineers: Midlands.—James Watt Memorial Inst., Birmingham. Chairman's address, Mr. E. L. Cotterell. 6.30 p.m.

Inst. of Electrical Engineers: N.E. Centre Students.—At Armstrong College, Newcastle-upon-Tyne. "The Dunston 50-cycle Power Station," Mr. A. S. Carr. 7.15 p.m.

Junior Inst. of Engineers.—At 39, Victoria-street, S.W.1. "The Electrolytic Theory of Corrosion," Mr. H. E. Yerbury, M. Inst. C.E., M.I. Mech. E., M.I.E.E. 7.30 p.m.

Royal Inst. of Great Britain.—21, Albemarle-street, W.1. Discourse, Mr. E. V. Appleton. 9 p.m.

Saturday, October 28th.

Hull Assoc. of Engineers.—Municipal Technical College, Park-street, Hull. "Experimental Research on Boundary Lubrication," Mr. J. E. Southcombe. 7.30 p.m.

Inst. of British Foundrymen.—The Technical College, Derby. "Technical Control in the Small Foundry," Mr. J. G. Pearce. 6 p.m.

Royal Inst. of Great Britain.—21, Albemarle-street, W.1. "The Course and Causes of the World Depression," Mr. L. C. Robbins. 3 p.m.

Stephenson Locomotive Society.—Visit to Stratford, L.N.E. Railway Running Sheds. 2.30 p.m.

Monday, October 30th.

Bradford Engineering Soc.—Technical College, Bradford. "Salvage Work on the Ex-German Fleet at Scapa Flow," Mr. E. F. Cox. 7.30 p.m.

Inst. of Automobile Engineers.—At 39, Elmbank-crescent, Glasgow. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7.30 p.m.

Inst. of Mechanical Engineers: Graduates.—Storey's-gate, S.W.1. "Stainless Steels in Aeroplane Structures," Mr. F. J. Murdoch. 6.45 p.m.

Tuesday, October 31st.

Inst. of Transport.—At Inst. of Electrical Engineers, Victoria Embankment, W.C.2. Discussion, "The Duties of a Modern Transport Manager," Mr. M. F. Barnard.

Wednesday, November 1st.

Inst. of British Foundrymen.—At Charing Cross Hotel, London, W.C.2. "Cupola Practice," Mr. L. W. Bolton. 8 p.m.

Inst. of British Foundrymen.—Technical College, Corporation-street, Preston. "Manufacture and Application of Centrifugal Castings," Mr. T. R. Twigger. 7.30 p.m.

Inst. of Physics.—In the Royal Institution, 21, Albemarle-street, W.1. "Physics in the Building Industry," Dr. R. E. Stradling. 5.30 p.m.

Royal Soc. of Arts.—John-street, Adelphi, W.C.2. Presentation of medals. Address, "Quality," Mr. John A. Milne. 8.30 p.m.

Thursday, November 2nd.

Inst. of Automobile Engineers.—Queen's Hotel, Birmingham. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 8 p.m.

Inst. of British Foundrymen.—At James Watt Memorial Inst., Birmingham. "The Education of Foundry Workers," Professor J. H. Andrew. 7.30 p.m.

University of London.—King's College, Strand, W.C.2. Department of Mechanical Engineering. "Injection and Combustion in High-speed Oil Engines: iii., Injection: Processes in Injection Systems," Dr. S. J. Davies. 5.30 p.m.

Friday, November 3rd.

Faraday House Old Students' Assoc.—At Savoy Hotel, W.C.2. Twenty-fifth annual dinner.

Inst. of British Foundrymen.—Municipal College, Ormerod-road, Burnley. "Continuous Casting Plant," Mr. F. J. Cook. 7.15 p.m.

Inst. of Marine Engineers.—Grosvenor House, Park-lane, W.1. Annual conversazione. 7 p.m.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. Thomas Hawksley Lecture, "Kinematic Design in Engineering," Professor A. F. C. Pollard. 6 p.m.

Junior Inst. of Engineers.—39, Victoria-street, S.W.1. "Safety and Efficiency in Electrical Installation Work," Mr. W. F. C. Cooper. 7.30 p.m.

Railway Club.—57, Fetter-lane, E.C.4. "Train Ferries: Their History and Development," Mr. S. R. Yates. 7.30 p.m.

Saturday, November 4th.

Inst. of British Foundrymen.—At Engineers' Club, Manchester. "Continuous Casting Plant," Mr. F. J. Cook. 4 p.m.

Inst. of Electrical Engineers: North Midland Students.—Visit to the Hunslet Engine Company, Ltd., Jack-lane, Leeds. Meet at Corn Exchange, Leeds, 2.30 p.m.

Tuesday and Wednesday, November 7th and 8th.

Inst. of Gas Engineers.—At Inst. of Mechanical Engineers, Storey's-gate, S.W.1. Fifth autumn research meeting. Morning sessions, 10 a.m.; afternoon sessions, 2.30 p.m.

Thursday, November 9th.

Inst. of Marine Engineers.—85–88, The Minories, E.C.3. Junior Section. "Pumps for Marine Service," Mr. F. M. Jones. 7 p.m.

Inst. of Structural Engineers: Yorkshire.—Hotel Metropole, Leeds. "Designing for Welding," Mr. C. Helsby. 7 p.m.
